4191. *Potato starch may be detected in flour* by examination with a microscope; the grains of starch may be seen of a round form, and to possess a glistening appearance, which is not the case with flour. See "Starch," Book VII., Chap. VIII., Sect. II.

4192. *Common salt*, which is essential to bread in a small quantity, is rarely employed in too great proportion as a fraud. Salt has the property of causing the dough to take up more water than it otherwise would, and thus increases the weight of the bread; but as this increase is mere water, the bread gains nothing in nutritious quality. This kind of adulteration, however, is not likely to be carried to any great extent, as the saltness of the bread will be complained of.

4193. *Sand* is sometimes found in bread; but this cannot be supposed to be introduced purposely by the miller or baker. The sand is derived either from grain badly cleaned, or more frequently, perhaps, from the wearing away of bad millstones. In some parts of the country, the millstones being of too soft a material is not unfrequent. This accident is a serious evil, as fine sand is extremely prejudicial.

4194. *On the Continent*, bakers appear to be no less ingenious than in this country in the contrivance of adulterating processes. Some time ago the bakers of Lisle were detected in using sulphate of copper (blue vitriol), a poisonous substance, in bread, to correct the qualities of bad flour.

SECT. VI.—HOME-MADE BREAD.

4195. Hitherto we have treated of the general principles of the art of making bread, which cannot but be desirable to be understood by those who have the management of a family; and we stated in our introduction, Sect. I., that the convenience of having public bakers almost in every village has, in many places, superseded, in a great degree, the necessity for baking at home; nevertheless, domestic baking is very generally practised in the country; and one advantage of this is, that bread can be secured from any adulteration, and may be had of the best quality. It has been said justly that "the evils of adulteration are probably exaggerated;" but, with some persons, the suspicion that they are eating other substances than the produce of wheat is painful enough. In general, good home-made bread is observed to be more full of flavour than that of the baker, to keep better, and to go farther, being more nutritive. In many families, a difficulty occurs respecting the oven; one built of brick is the best; and, where the family is large, a bake-house is found an important requisite; but perfectly good bread may be, by proper management, baked in iron and other ovens on a small scale, and we must refer the reader to the article "Description of Ovens," Sect. IX., Chap. III., where the various kinds will be treated of.

4196. *With respect to the economy or saving in baking bread at home*, some persons consider that it is so little as not to deserve attention except the family be large. This depends much upon opinion, but it is well to see what the cost actually is, in order to determine this question. The following calculation, given in an excellent little work entitled "Cottage Comforts," will place this in a clear light: "The expense of making a bushel of wheat into bread will be as follows: Wheat, 9*s.*; grinding, 9*d.*; yeast and salt, 3*d.*; heating the oven, 1*s.*; in all 11*s.*; but from this you must deduct at least 6*d.*, as the bran and pollard, of which you have 13 lbs., is worth more than ½*d.* per pound. I have also rather overcharged than otherwise on the other things. Salt, now the tax is taken off, is very cheap; yeast, if you have brewed lately, you need not buy, and 1*s.* is perhaps more than ample allowance for heating the oven; perhaps 10*s.* will be about a fair calculation for the baking. From your bushel of wheat you will get from 58 to 59 lbs. of bread, that is, about thirteen loaves and a half of 4 lbs. each, which will cost you, at the baker's, 11*s.* 9¾*d.* Should there be no convenience for grinding, the best white flour may be purchased, of good quality, usually at about 5*s.* 6*d.* per bushel of 56 lbs." From this it is obvious that the saving is not great, and that the baker's profits cannot be considerable, if the materials he uses are of the best kind; but it is also obvious that it is possible to make bread at home, of the very best quality, at least as cheap as it is sold by the baker, with the certainty of its being genuine.

If a certain proportion of potatoes are added to the flour, as is the practice with the bakers, then the bread will be cheaper, weight for weight, but the real saving will be little, as the potatoes contain so much water; added to which, bread into which potatoes enter as an ingredient is decidedly somewhat less nutritive, though very white, and keeps worse, becoming dry and hard in less time.

4197. *To make good Family Bread.*—The general mode of making bread fermented with yeast must be nearly the same in all cases; and we have already described the method as practised by the public baker; but we consider it proper to describe, likewise, the process as it is employed in private families, where the scale is of course less. We will suppose that a bushel of wheat flour is to be baked into bread; if the quantity be less, then all the ingredients must be diminished in proportion, observing that a bushel of flour weighs fifty-six pounds. If the family be large, it may be supposed to consume that quantity weekly; but in a small family of three or four persons, twenty pounds of flour may perhaps be found sufficient for the weekly batch. Put the flour in one heap into a wooden trough that is made for the purpose, or into a smooth tub or pan sufficiently large to hold near twice the quantity, but not too deep. Then mix a pint of good stiff brewer's yeast with a pint of lukewarm water, and a quarter of a pound of salt, and strain it through a sieve; with a spoon, work as much flour into it as will make the whole of the consistence of a thin batter, and stir this together well. Make a large hole in the middle of the heap of flour, and pour this mixture into it; sprinkle some dry flour over this, so as just to cover it. The sponge being thus set, cover the whole over with a cloth, and place it in a warm situation, nearer to, or farther from the fire, according to the state of the weather, whether it is hot or cold.

The sponge will now ferment and swell up, or *rise*, as it is called; and, as it rises, cracks will be seen across the flour that was scattered over it. The whole of the flour is now to be mixed up with the mass in which the fermentation has already taken place; mixing in as much water as is necessary, and taking care to add it a little at a time. The whole must now be very well kneaded together into dough. Much of the goodness of the bread will depend upon the thorough kneading, in order that all the lumps of flour may be completely moistened and broken, and the fermented batter intimately mingled with the dough, so that it may be as uniform as possible.

At first, the mass is very adhesive, and clings to the fingers, but it becomes less so the longer the kneading is continued; and when the fist, on being withdrawn, leaves its perfect impression in the dough, none of it adhering to the fingers, the kneading may be discontinued. The dough is now to be made up into a lump in the middle of the trough, a little flour is dusted over it, and it is placed in a warm situation to ferment, and rise still more. In about half an hour or more, according to circumstances, it will have risen sufficiently; and before it has time to fall back again, it is cut into pieces of the required sizes for loaves, and made up into shape, ready to be put into the oven, and dusted over with flour. No more should be done than is necessary to bring the loaf into shape, since much handling in this stage of the dough is apt to make the bread heavy.

In the mean time, while this was going on the oven should be heated either with wood or by a coal fire, according to its construction, for which see "Oven," Sect IX It is difficult to describe the degree of heat that is proper for the oven; but persons accustomed to bake in a brick oven guess this pretty well by the bricks being red-hot, and the degree of heat which they feel on their faces. The hot embers are now to be drawn out of the oven; if that is of brick, this is done by a long pole with an iron hook; and the bottom is farther cleaned with a mop made of shreds of cloth or sacking. No time should now be lost in putting in the loaves, by means of a proper wooden shovel, called a *peel*, and the oven door should be shut very close; the bread should be looked at when it is supposed to be nearly done, which is generally in about two hours, more or less, according to the size of the loaves. When the loaves are taken from the oven, they should be placed with their bottoms upward, and covered with a thick cloth or flannel, that they may cool gradually.

If the fermentation of bread be too rapid, as it sometimes will be in warm weather, or if too much or too strong yeast has been used, there is a danger of the dough souring by passing into the acetous fermentation. If that should happen, it will become heavy. To check this, it is customary to uncover the dough, and expose it to the air, in order to diminish the temperature of the fermenting mass, or to put it, if possible, in a cooler place. Chaptal proposes to knead a little carbonate of potash with the dough, which will neutralize the excess of acetic acid; magnesia has also been tried for the same purpose; but though these practices may be very proper were bakers scientific, they will frequently fail with our present makers of bread.

4198. *Household*, or *Brown Bread.*—In Sect. II. we described the different kinds of flour prepared from wheat, produced by the mode of dressing it after it was ground; and we showed that the finest and whitest part lay in the centre, or heart of the grains. Originally, the distinction of the kernel and the pollard was neglected by the miller; and, after taking off the bran, the whole was ground together. Future refinements found means to separate the pollard from the kernel, in order to produce a very white flour. There are many persons, however, who consider the *whole flour*, or *grist flour*, as it is called, that is, the pollard and the kernel ground together, as formerly, to be more wholesome than the white flour alone; and this is still extensively used, particularly in the country. Bread made of this is generally known by the name of *household*, or *brown bread.*

Brown bread certainly possesses some qualities peculiar to itself. Its flavour is somewhat sweeter than white bread, and it keeps longer moist, as it absorbs more water; but when it dries it is apt to crumble; it likewise appears to agree better with some constitutions, and on that account it is occasionally preferred.

One of the advantages of grinding our flour at home is, that it may be bolted and separated in any way that may be desired. There is nothing in the baking of brown bread different from that of white; it is now frequently made and sold by the London bakers at a somewhat lower price than white bread.

4199. *Brown Bread with the Bran.*—This is the coarsest sort of brown bread. If a Winchester bushel of wheat is sent to the mill and ground, the meal, including the bran, will weigh fifty-eight or fifty-nine pounds. To make bread of it, mix as much of the meal as is required with water, and add yeast and salt in the usual manner. The dough, before it is put into the oven, will weigh eighty-eight pounds. It may be divided into eighteen loaves, which, when baked, will altogether weigh seventy-four pounds and a half.

4200. *Pan Loaves.*—In many families a preference is given to what are called pan loaves, as being of firmer consistency and better flavour than loaves baked in the ordinary way. The dough is made nearly in the same manner as has been already described, but it is not so stiff as the dough for common bread. After having been suffered to rise for some time, it is divided into portions of the size required, and placed in earthen pans, or in square sheet iron ones tinned. The rising having continued for a short time, the surface of the dough in each mould is pierced with a fork or similar instrument, to prevent inequalities or blisters in the crust. They are then placed in a quick oven, and when nearly done are taken out of the moulds and transferred to flat tins, on which the baking is completed. Iron ovens answer better for these than for the ordinary kind of loaves.

4201. *Rye, and likewise barley, are sometimes made into bread by fermenting them with yeast*, in the same manner as wheat flour; but barley requires the dough to be baked very soon after it is made, as it grows sour almost immediately.

Sect. VII.—FANCY BREAD.

4202. There are many forms of bread which come under this designation; and the bakers seem to vie with each other in producing new varieties. As few of these are made in private families, and as those conversant with the practice of baking will find no difficulty in imitating them, it is not necessary to enumerate them all. We shall describe those kinds that are in general use only.

4203. *Rolls* are made from dough of a less dense consistency than that which is intended for common bread, and when baked they are more porous and lighter than ordinary bread. The London bakers prepare both kinds by the same kneading, and leave the portion intended for the lighter bread in the trough after the loaves have been put into the oven, that the rising may continue a little longer. When the rising is sufficient, the mass is formed into rolls, which are deposited in a warm place, and allowed to expand as much as possible. The baking is effected in twenty or thirty minutes.

4204. *French Bread.*—The French make a great many more varieties of bread than we do; some coarser, and others finer than ours.

To make French bread of a superior kind, put a peck of flour into the kneading trough, and sift it through a wire sieve; then rub in three quarters of a pound of butter, and, when it is intimately incorporated with the flour, mix up with it two quarts of warm milk, a quarter of a pound of salt, and a pint of yeast; in mixing these with the flour, a sufficient quantity of water must be superadded to make a dough; after the kneading, it must stand for two hours to rise; it must then be moulded into loaves, which are to be laid on tins and placed for an hour by the fire, or in a hot closet. They are placed in an oven (a brick oven is best) for twenty minutes, and when drawn are divested of the friable crust by rasping; but some prefer not to rasp them.

4205. *Muffins* are made from a light paste prepared in the following manner: To a quarter of a peck of flour add three quarters of a pint of yeast, four ounces of salt, and as much water or milk, slightly warmed, as will form a dough of rather light consistence. Small portions of this dough are put into holes made in a layer of flour about two inches thick, placed on a board; and the whole is covered up with a blanket, and laid near the fire to promote the rising. When this has been effected, the portions, which are now of a semi-globular form, are removed to a heated iron plate to be baked When the muffins begin to acquire a brown colour on the lower side, they are turned and baked on the other.

4206. *Crumpets* are made thus: The usual ingredients are one pound of flour, three table-spoonfuls of yeast, and a sufficient quantity of milk or water to form a fluid paste. After having been suffered to rise, a portion of the fluid is poured on a heated iron plate, and baked quickly on either side successively, like a pancake.

4207. *Gingerbread* is made from a dough composed of one pound of fine pollard, three quarters of a pound of treacle, half an ounce of the sub-carbonate of potash, half an ounce of butter, with warm water sufficient to make it knead. Several spices are added, as ginger, cinnamon, nutmeg, allspice, Cayenne pepper or black pepper. The dough is kept for several days, sometimes nearly a fortnight, till a rising or fermentation is produced by the action of the acid of the treacle and of the sub-carbonate of potash, by which carbonic acid gas is disengaged very slowly; it is then baked.

4208. Besides the various preparations which we have described, and which go under the general denomination of bread, a great many others are made by the confectioners and biscuit bakers, which are not fermented but are rendered either brittle, or *short*, by the admixture of various substances, as milk, eggs, sugar, butter, and seasoned with seeds, spices, currants, &c. These will be treated of under "Confectionery," Book XV., Chap I.

Sect. VIII.—Receipts for making yeast.

4209. The difficulty of procuring yeast for baking, particularly in country places, at a distance from breweries, constitutes, sometimes, a great inconvenience. Many endeavours have therefore been made to obviate this difficulty by the discovery of an easy mode of forming or of preserving yeast. We shall describe some of the best of these.

4210. *The following method is stated by Mr. Fownes in the "Philosophical Magazine:"* If common wheaten flour be mixed with water to a thick paste, and exposed, slightly covered, to spontaneous change in a moderately warm place, it will, after the third day, begin to emit a little gas, and to exhale an exceedingly disagreeable sour odour, much like that of stale milk; after the lapse of some time this smell disappears, or changes in character; the gas evolved is greatly increased, and is accompanied by a very distinct, and somewhat agreeable vinous odour; this will happen about the sixth or seventh day, and the substance is then in a state to excite fermentation. A quantity of brewer's wort is next to be prepared in the usual manner, by boiling with hops; and when cooled to 90° or 100°, the altered dough above described, after being thoroughly mixed with a little lukewarm water, is added to it, and the temperature kept up by placing the vessel in a warm situation. After the lapse of a few hours active fermentation commences; and when that is complete, and the liquid clear, a large quantity of excellent yeast is found at the bottom, well adapted to all purposes to which that substance is applied.

4211. *Another Method.*—Take sixteen parts of ground malt, and add to it five parts of honey and one of powdered tartar; mix the whole with water warmed to 122°, and place it in the proper temperature for fermentation; yeast will be produced, which must be taken off in the usual manner.

4212. *Method of making Yeast by the late Dr. Henry.*—Boil flour and water to the consistence of treacle, and when the mixture is cold, saturate it with carbonic acid or fixed air. Then pour it into large bottles with narrow mouths, which should be loosely covered with paper, and a weight to keep it down. Place them in the temperature of 70° or 80° for twenty-four hours, stirring it two or three times. At the end of this time it will have fermented so much as to be of the consistence of yeast. Incorporate the dough to be made into bread with this artificial preparation, in the proportion of six pounds of the former to one quart of the latter, and a due quantity of warm water. The whole must now be kneaded together, covered with a cloth, and suffered to stand till it be sufficiently fermented, which, perhaps, may require twelve hours, when it should be formed into loaves and baked. Dr. Henry proposes this as a method that might be useful in making yeast for baking at sea. In order to produce the carbonic acid in this way of making yeast, some have used the common soda powders, and have proceeded in this manner. Some flour and water are boiled into thin paste, and a little of the soda powders (carbonate of soda and tartaric acid) mixed together stirred in; this will produce the carbonic acid gas, and the whole should be well stirred with a whisk, and kept in a warm place. It will soon ferment, and be a strong yeast. It is necessary that the two powders should be in such proportions as to neutralize each other, otherwise the dough will taste acid or alkaline. The salt will give the bread somewhat of an aperient quality, but it will be perfectly wholesome.

4213. *Dr. Lettsom's Method of making Yeast.*—Thicken two quarts of water with four ounces of fine flour; boil it for half an hour, then sweeten it with three ounces of brown sugar; when almost cold, pour it, with four spoonfuls of baker's yeast, into an earthen jug deep enough for the fermentation to go on without running over; place it for a day near the fire, then pour off the thin liquor from the top, shake the remainder, and close it up for use; first strain it through a sieve. To preserve it sweet, set it in a cool cellar, or hang it some depth in a well. Keep always some of this to make the next quantity of yeast that is wanted.

4214. *Yeast from Potatoes.*—Choose some potatoes of the mealy kind that are quite sound, and boil them; skin and mash them very smooth with boiling water; add water till they are of the consistence of common beer yeast, not thicker; then add two ounces of treacle to every pound of potatoes, and while the whole is yet warm, stir in for every pound of potatoes two table-spoonfuls of yeast. Set this before the fire, and it will soon begin to ferment, and in twenty-four hours, perhaps, the fermentation will be at the greatest height, when the yeast will be fit for use. Some add a little honey or other saccharine matter to the mashed potatoes.

4215. *Yeast cakes are made in America for the purpose of baking*, and are thus described by Cobbett in his "Cottage Economy:" "The people of Long Island make a parcel of these cakes once a year, and when they bake, they use them instead of leaven. To make them, they use three ounces of good hops, three pounds and a half of rye flour, seven pounds of Indian corn meal, and one gallon of water. Rub the hops so as to separate them. Put them into the water, which is to be boiling at the time. Let them boil half an hour; *then strain* the liquor through a fine sieve into an earthen vessel. While the liquor is hot put in the rye flour, stirring the liquor well, and quickly, as the rye flour goes into it. The day after, when it is working, put in the Indian meal, stirring it well as it goes in. Before the Indian meal be all in, the mass will be very stiff; and it will, in fact, be *dough*, very much of the consistence of the dough that bread is made of. Take this dough, knead it well, as you would for pie-crust, roll it out with a rolling-pin as you roll out pie-crust, to the thickness of about a third of an inch. When you have it, or a part of it at a time, rolled out, cut it up into cakes with a tumbler glass turned upside down, or with something else that will answer the same purpose. Take a clean board, a *tin* may be better, and put the cakes to dry in the sun. Turn them every day; let them receive no wet, and they will become as hard as ship biscuit; put them into a bag or box, and keep them in a place perfectly free from damp. When you bake, take two cakes of the thickness above mentioned, and about three inches in diameter; put them in hot water over night, having cracked them first. Let the vessel containing them stand near the fire-place all night; they will dissolve by the morning, and then you use them in setting your sponge, as it is called, precisely as you would use the yeast of beer. White pea meal or barley meal will do as well as Indian meal."

4216. *Methods of preserving Yeast.*—For this purpose, it may be pressed in a bag, so as to separate the chief part of the water, and then exposed to a gentle heat on a sieve; by this it will be dried into a hard, granular substance, or coarse powder, which retains all the original properties for a great length of time, if packed into a bottle, jar, or cask, and kept from the air and quite dry. By drying, it is reduced to one third of its weight. This method has been long practised in Holland and Flanders with perfect success, and it is extremely useful; for fluid yeast in warm weather soon becomes sour and putrid, and not only loses its properties, but imparts a most disagreeable flavour to the bread where it is used.

4217. *Another method* by Thenard is as follows: Dip some twigs in yeast, and dry them in the air. This is commonly practised.

4218. *Another Method.*—Work it round with a whisk until it becomes thin; then spread it with a brush over a piece of clean wood, and dry it in the air; when that coat is dry, lay on another, and repeat this till the quantity is an inch or two in thickness; when it is thoroughly dry, put it into close bottles or canisters; or it may be spread and dried on a clean wooden bowl, and a piece cut off as it may be wanted. It should be dissolved in warm water when it is to be used for baking or brewing.

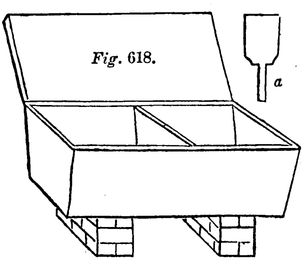
4219. *In Germany* they put the yeast into bags, which they surround with wood-ashes, which will absorb all the moisture from the yeast; then they form it into balls, which they keep in a dry place.

What is called *levure* in France is the yeast and lees of beer put into canvass bags to drain, and some water added to assist in carrying off the bitter flavour of the hops; it is sent from Flanders to Paris for the use of the bakers.

SECT. IX.—ON THE BAKE-HOUSE; CONSTRUCTION OF OVENS FOR BAKING BREAD; AND REMARKS ON THE PROCESS OF BAKING.

4220. In large establishments, where the offices are complete, the bake-house is a distinct apartment, fitted up in a convenient manner. It should have a good light, should contain the ovens, kneading-trough, chests for flour and other materials, a strong table, presses, or cupboards to hold various articles, and should be supplied with water by a pipe. *Fig.* 618 represents the usual form of the kneading trough; and the chests for the flour may be of the same form, and should be placed at one end of the trough, there being a table at the other; and *a* is a wooden scoop to scrape the dough from the sides of the trough.

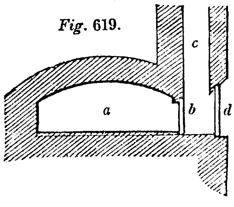
Fig. 618.



4221. *The ovens* employed by the bakers, and likewise in general use by families in the country, where sometimes a considerable quantity of bread is prepared, are built of bricks.

4222. *The common brick oven* is of a circular or oval plan, and is arched over with good sound bricks, the bottom being laid with flat tiles closely jointed. The woodcut, *fig.* 619, represents a vertical section: *a* is the cavity of the oven, arched over where the bread is put. The oven is heated by wood, introduced by the door *d*, laid upon the floor and kindled. When the bricks are sufficiently hot the fire is withdrawn, and the ashes carefully swept out, when the bread is introduced. While the wood is burning the smoke goes up through the flue *c;* but when the bread is put in, the inner door, *b*, is closed, and likewise the outer, *d*, to keep in the heat. The bread is baked merely by the heat of the brick-work, and when it has remained a sufficient time, the doors are opened, and the baked bread is taken out.

Fig. 619.



4223. *Coal is now very generally employed by bakers* in towns for heating the oven, instead of wood, and is found to answer perfectly, at less expense. *Fig.* 620 represents the plan and section of the usual construction of a *London baker's oven heated with coal:* *a* is a *plan* of the body of the oven, of which *s* is a section; *b* the door; *c* the fire-grate and furnace; *d* the flue to carry off the smoke after it has circulated round the oven.

When the bread is taking out there is a great deal of steam and hot air, and these are carried off by another short flue, *e*, over the door, that goes into the flue *d*; this steam flue has a damper to shut it when it is not wanted, represented in the section; and the smoke flue has also a damper, to be shut when the oven is sufficiently heated. A small pan is sometimes put over the fire-place for heating water. In using coal, some management is requisite to burn away the soot which at first adheres to the inside of the oven, and blackens it; but when the fire gets clear this soot is burned away, and the oven is quite clean.

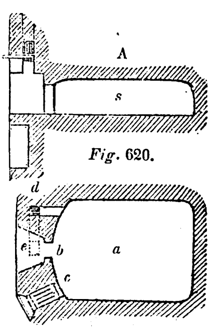


Fig. 620.

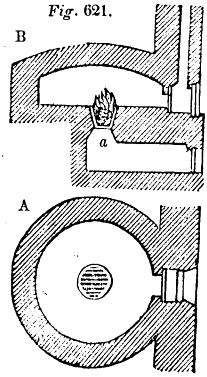
4224. *Fig.* 621 *exhibits the plan,* A, *and section,* B, *of another construction of oven to be heated with coal.* In this the fire is made on *a*, a small moveable grate, made in form of a garden pot, placed in a hole in the middle of the floor, supplied with air from beneath. When the oven is heated, this grate is to be lifted out with the fire, and the aperture covered with an iron cover. The situation of the flue is the same as in the last construction. This plan has the advantage of being easily cleaned out.

Fig. 621.



The kind of coal which answers best for heating the oven is that which is called *swift* in burning. Scotch coal is therefore excellent. When *Troone* coal can be procured, it is always to be preferred. The fire-place has double doors, which, of course, are of iron.

4225. *The common brick oven for baking, heated with wood, is the cheapest, simplest, and most durable,* and, consequently, the fittest for cottages or small houses in the country, particularly where there is plenty of wood or fagots to burn. When properly heated, it is superior to any other, and possesses what bakers term a "soaking heat," that is, a uniform, lasting heat, that penetrates the bread perfectly; but in numerous situations, particularly in towns, they are scarcely admissible, and likewise where wood is scarce or expensive.

4226. *Iron ovens are, therefore, frequently more convenient, and even more economical.* There are many persons who imagine that it is quite impossible to bake bread and pastry well in an oven of iron; but this opinion arises from want of experience. It must be observed that much more skill is required in fitting up and managing an iron oven than a brick one; but when the former are fitted up in a proper manner, and persons understand the method of using them, they answer the purpose very well, and have, at the same time, many advantages in baking on a small scale.

The brick oven is a long time in heating, and when used only once or twice a week it is difficult and tedious to bring it to that state which bakers consider to be the right degree; and without that the bread will be imperfectly baked; whereas, iron ovens are soon heated, although the heat is more liable to be unequal, and requires more care in the management of it.

Small iron ovens, very convenient for families, are usually now attached to kitchen ranges, and will be described under "Kitchen Furniture;" though these seldom answer for baking bread: others are made of a portable kind; but the best iron ovens are fixed up separate on purpose for baking bread and pastry. It is essential that the circulation of the smoke and heat should go all round the oven; and when the fire is below, they are apt to be hotter at the bottom than at the top. To defend the bottom from too great heat, it is frequently necessary to put a piece of tile, or fire-stone, or a tray with sand, on the bottom of the oven.

4227. *The simplest kind of oven* is a metal pot or kettle, inverted and covered with live coals. In new settlements, like those in Canada, the most simple contrivances are often the most desirable, as being the most easily put in practice in the infant state of society; and many a valuable hint may be borrowed from the make-shifts which necessity suggests When an oven is not attached to the house, and there is no convenience for constructing one within doors, the oven is sometimes made out of doors, and wholly detached from the dwelling. They are built of clay, somewhat in the form of a large bee-hive, and placed, like it, upon four posts stuck in the earth; and whenever these ovens are not prepared, the bread is baked upon the earth in large iron pots called *bake-kettles*. A flat iron plate, from fifteen inches to two feet in diameter, is first heated by burning fuel on it, or by any other means. It is then swept clean, and a little flour is sprinkled over it, to prevent the bread from adhering. An iron kettle is then placed over this, with its mouth downward, and a fire is kindled upon its bottom, the sides being also surrounded by fire. The heat of this fire striking downward through the kettle, bakes the bread, pastry, meat, or whatever may be required. This mode, like confined ovens, does not admit of any escape of steam; which, in some cases, is an advantage, in others, the contrary. The time necessary for baking can be determined only by experience; but two hours is that which bread usually requires in a common oven.

4228. *Observations on baking meat* and pastry will be given in the description of the processes of cookery.

4229. *To bake properly requires Attention to several Circumstances.*—The heat of the oven must be *just sufficient*, otherwise the bread will not be well baked. If the heat is not enough, the bread will be soft and wet, or pasty; and if the oven be over hot, it will form too hard a crust, which will lock up the water in the bread, or this will be burned. To ascertain when it is heated just enough demands considerable practice. There are, however, several signs which may be observed to assist the operator. Some try the heat by putting in a green vegetable; if this is scorched, the oven is too hot; but the best method is to sprinkle some flour upon the floor of the oven; if this takes fire, or is burned black quickly, the oven is heated too much, and must be suffered to cool; when the heat is proper, the flour should only turn black without taking fire. Every kind of flour is not proper for this test; old flour will burn with a heat that will scarcely blacken new flour, and will therefore lead to an error. The newest flour is the most proper for trying the heat of the oven. Experienced bakers form an opinion of the proper heat of the oven from the appearance of the brick-work in the arched roof; when that is sufficiently hot, it has burned away the soot which lodged upon it when the fire was first kindled, and has become quite clean. Also, if the point of a stick be placed on the heated bricks, it will take fire, and by rubbing the charcoal will make a black mark; but this mark will disappear instantly by being burned off if the bricks are sufficiently hot.

4230. *Experiments have been made to ascertain what is the actual degree of heat in a baker's oven* when fit for baking bread; and it has been stated to be about 270°, which is 58° above the heat of boiling water. The baker's oven has afforded some remarkable facts demonstrative of what the human constitution is capable of enduring, and likewise of one of the properties of air. The German ovens are too deep from the front to the farther end to allow of arranging the loaves conveniently; and it is a common practice in Germany for girls to go into the ovens and stay for a few minutes to arrange the bread. The reason why this great heat is not felt so much as might be supposed, is because the feet are cased in flannel, and also because air does not part with its heat so readily as solid bodies.

4231. *The shapes given to bread are extremely various;* and this is a matter of some importance, as the quality sometimes depends, in a great measure, upon it. The common shape of the loaves made by the baker in England is nearly cubical, but rather a short prism with six unequal sides, a form which is produced by the mode of baking. The dough is first made into the form of two thick cakes, and these are pressed together by the baker's elbow, which is the cause of the deep indent seen on the top of the loaf. The loaf is thus nearly of a globular form; and as they are placed in mutual contact in the oven, by their swelling they press against each other, and produce flattened sides; in consequence, sometimes, they do not separate very readily where they ought, and one of the alleged uses of the alum is to facilitate this separation. One of the reasons for packing the English bread so close together in the oven is that they may take up little room; and another, that they may lose as little in weight as possible, in consequence of which the quantity of crust is small; and this kind of bread is often not sufficiently baked. In the English common loaves, the sides where they are in contact with each other have no crust; and the upper crust differs from the lower from this circumstance: the heat which radiates from the brick-work which forms the top of the oven, and which is conveyed by the hot air from the furnace, is greater than that which is given out by the tiles on which the loaves rest. Several other shapes, however, have been lately introduced by our bakers; and these are baked without being in contact in the oven, by which the crust is increased.

4232. *The imperfect baking which we often see in bakers' bread* is, no doubt, owing to the present law which fixes the weight of the loaf. The loss of weight is variable, according to the quality of the flour. In receiving bread from bakers in a hot state, there is sometimes a loss of five per cent. from evaporation; for this reason parish bakers always send in their bread hot to the work-house when they can. The average loss of weight in baking is about one eighth of the whole. Formerly we had peck loaves weighing 17 lbs. 6 oz.; half pecks, 8 lbs. 11 oz.; quarterns, 4 lbs. 5 oz.; and half quarterns, 2 lbs. 2½ oz. At present the loaf nearest to the old quartern is the 4 lb. loaf; if this proves 1 oz. lighter, the baker is liable to a penalty; hence the baker is tempted to underbake.

4233. *An oven for baking bread, heated by high-pressure steam,* has been made; but this was upon a large scale for a public company, and as it is not applicable to domestic purposes, it is unnecessary for us to describe it.

4234. *Baking by hot water* has also been attempted. To effect this, the hermetically-sealed tubes, filled with water heated to 300° and upward, have been used on the plan of Mr. Perkins; but this mode must likewise be evidently of very limited application.

SECT. X.—BREAD MADE OF THE MIXTURES OF VARIOUS GRAINS.

4235. Though wheat is the most valuable of the varieties of corn, yet it cannot be cultivated in very high latitudes, and demands a rich soil with plenty of manure; whereas some other kinds of grain, as barley, oats, and rye, will grow on comparatively poorer soils, and may be raised at a cheaper rate; these grains will, therefore, necessarily continue to supply the bread of northern nations. But even in many parts of Britain wheat cannot be successfully cultivated; and the crops are liable to fail through bad seasons or other unfavourable circumstances. The employment of other grains also for bread is, therefore, desirable; and many endeavours have been made to combine together the produce of several farinaceous substances, so as to obtain results that cannot be had from any one of them singly. It is important to record some experiments of this kind, as well as the practices of different times; and we shall describe several varieties of bread which have been found useful.

4236. *Bread of Potatoes with Wheat Flour.*—In describing bread made by professed bakers (Sect. IV.), we stated their practice of mixing some potatoes with their flour; but what we are now about to mention is bread made of potatoes with only flour sufficient to produce the necessary fermentation. In describing the composition of potatoes, we showed that their farina consisted almost entirely of starch without any gluten, and since the latter is the chief ferment, the farina of potatoes alone cannot be made into fermented bread. But if a certain portion of wheat flour be added, this mixture, worked into dough, will rise in the usual manner, the fermentation of the flour being communicated to the whole mass. To effect this, however, equal quantities of wheat flour and potatoes are necessary; and it is to be observed, that though the economy may be considerable, and the bread nutritious, yet it is much inferior to that of wheat alone, as it is apt to crack and crumble, and grow clammy when it is stale.

4237. *A sort of cakes may be made of potato flour, without mixing with any other,* as follows: "Its adhesive quality does not admit of baking or kneading unmixed with meal or wheaten flour; but it may be managed in this manner. A small wooden frame, nearly square, is laid on a flat pan like a frying-pan; this frame is grooved, and so constructed that, by means of a presser or lid introduced into the groove, the cake is at once fashioned according to the dimensions of the mould. The frame containing the farina may be almost immediately withdrawn after the mould is formed upon the pan, because, from the consistency imparted to the incipient cake by the heat, it will speedily admit of being safely handled. It must not, however, be fired too hastily, otherwise it is apt to become unpleasantly hard, and unfit for mastication. This precautionary measure being observed, it will be found that, when thoroughly ready, the bread of potato flour, even unaided by any foreign ingredient, will eat very palatably. It might then, from time to time, be soaked for puddings, like the tapioca; or it might be used like the capada cake, which, in appearance, it so much resembles; that is, when well buttered and toasted, it will make an excellent breakfast appendage."—*Quarterly Journal of Agriculture*, vol. ii., p. 69. It is to be observed here that this potato bread is not fermented.

4238. *Potatoes may be prepared to serve the purpose of bread* by simply boiling and cutting them into thin slices, which are dried thoroughly by a gentle and equal heat, for which purpose steam heat answers best. They may be close packed, and carried to any distance, or preserved for any length of time.

M. Parmentier observes that potatoes contain too much mucilage in proportion to their starch, which prevents them from being converted into good bread; but that if starch be collected from ten pounds of raw potatoes by grating them in cold water, and agitating them, and the starch thus produced be mixed with other ten pounds of boiled potatoes, and properly subjected to fermentation, like wheat flour, it will make good bread.

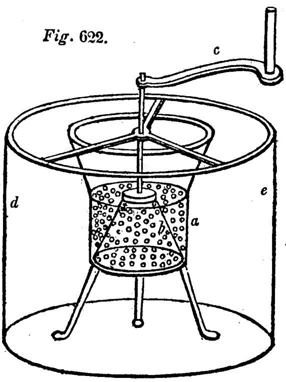
4239. *It has been justly stated, respecting making bread from potatoes*, that though that may be effected by various processes, and more especially by the mixture of different sorts of flour, yet they answer the purpose of food equally well, plain boiled or roasted, without all the trouble of such conversion.

4240. *Potato Flour.*—Sir G. Mackenzie, in the "Transactions of the Highland Society," observes that potato flour, boiled with milk and a little sugar, forms one of the most palatable, wholesome, and cheap dishes of which a labouring man can partake, and cannot be too strongly recommended to cottagers, who ought always to convert a portion of their potato crop into flour, to be used when fresh potatoes cannot be got. In fact, it is potato starch that very nearly resembles arrow-root, though inferior, and, at all events, would be a very desirable thing to have in a cottager's family as a light nourishing food in case of sickness.

4241. *The manufacture of potato flour* is carried on to a considerable extent in the neighbourhood of Paris, and the flour is sold at a price considerably higher than that of wheat, for the use of confectioners, and for bakers who prepare the finer sorts of bread, as it is remarkably white. The potatoes are washed and grated, and the flour, or starch, separated in the usual way of making potato starch; it is dried on shelves in a room heated by a flue, and afterward broken on a floor by passing a cast-iron roller over it; it is then passed through a bolting machine, and put up in sacks for sale. It is stated that 40,000 tons of potatoes are annually manufactured into flour within a circle of eight leagues around that city.—*Gardener's Magazine*, vol. vi.

4242. *A mill for grinding potatoes was invented by M. Beaume.* This mill, *fig.* 622, consists of two graters, made of sheet-iron, punched with holes; an outer one, *a*, cylindrical, and an inner one, *b*, conical; the bars made by punching point towards each other, and grind the potatoes which are put into the hopper above, and fall between the two graters, the inner grater being made to revolve by the handle, *c*. When the potatoes are ground, they fall through at the bottom into water contained in the large vessel, *d e*, in which the graters stand upon three feet. By this contrivance, which is so simple that it might be made by any country smith and carpenter, potatoes may be ground very expeditiously for starch, flour, or any other purpose.

Fig. 622.



4243. *A new species of bread has been made in Paris*, composed of potatoes or potato flour, and a small quantity of the gelatin procured from bones. This is said to be as nutritive as wheaten bread, and much less expensive. Biscuits have also been made upon the same plan. There can be no doubt that it will be nutritive and wholesome; but we would not hazard any opinion upon its comparative merits until it has been more tried. It might certainly, among others, be occasionally a useful resource.

4244. *Potatoes have been made to keep* by converting them into a kind of vermicelli. The potatoes are boiled or steamed, and their pulp forced through a colander fitted with a piston and cylinder; the pulp when it comes out is dried, and may be ground, or used as vermicelli.

4245. *Bread made of barley-meal* is considerably improved by the addition of wheat flour. It is always best to set the sponge with wheat flour altogether, as barley-meal does not ferment readily with yeast, and to add the meal when the dough is about to be made. This bread requires longer time to bake, and a greater heat than wheat bread. It is much used in Yorkshire, and also in Devon, and by the miners in Cornwall.

The following receipt is from the reports of the Board of Agriculture: "Mix two bushels of wheat flour, extracting only a very small quantity of the coarser sort of bran. Add one bushel and three quarters of barley meal. Make this into dough, with salt, yeast, and warm water, and bake for three hours and a half."

4246. *Bread made of Rye and Wheat.*—Equal quanties of wheat and rye flour, made and baked in the usual way, make very good and cheap bread.

4247. *Bread of Wheat and Turnips.*—Mix equal quantities of wheat flour, and turnips boiled, mashed, and having the water well squeezed out. Make the dough in the usual way, and bake it a considerable time. This kind of bread was made in England in a time of scarcity, in 1629, and again in 1693. It has a peculiar taste, by no means disagreeable; it is as light and white as wheaten bread, and should be kept twelve hours before it is cut, when the smell and taste of the turnip will scarcely be perceptible.—*Phil. Trans.* Carrots and parsnips may be treated in a similar manner with turnips. Also, mixtures may be made of wheat with oats, buckwheat, or any other farinaceous substance; all these may be fermented, as wheat flour contains the principles necessary for fermentation.

4248. *Rice Bread.*—In this country rice is rarely made into bread by itself, though it may be by the following process: Let a sufficient quantity of rice flour be put into the kneading trough; at the same time, boil a due proportion of water in a caldron, and throw in a small quantity of ground rice, which must be boiled until the decoction forms a thick viscous substance, which is poured upon the flour, and the mass is kneaded with a mixture of salt and yeast. The dough is then covered with a warm cloth, and left to rise. As the fermentation proceeds, the dough, which at first was firm, becomes almost fluid, and seems totally incapable of being moulded by the hand: to prevent the inconvenience and loss which would ensue from its spreading, a tin box is prepared, with a handle long enough to reach the end of the oven; a little water is poured into it, and it is then filled with dough, over which are laid some cabbage leaves, and a covering of paper. The box is deposited for a short time in the heated oven, and then suddenly reversed, so that the dough retains its place in the mould, and is converted into a loaf of the same form. The bread is of a fine yellow colour, as if it had eggs in it, and is very agreeable to the taste; but it must be eaten while fresh, as it loses much of its flavour on becoming stale. This bread is also useful to put into soups.

4249. *Rice, when made into bread, is more frequently mixed with some other grain.* The following are modes in which it has been so employed with advantage:

1. The Americans make bread with it in this manner. The rice is thoroughly cleansed by pouring water upon it and stirring it, the water being changed occasionally until all impurities are washed away. The water is then drawn off, and the rice, while yet damp, is bruised in a mortar; it is then dried and passed through a hair sieve. The flour thus obtained is generally kneaded with a small quantity of Indian-corn meal, and is boiled until it has acquired a thickish consistence; sometimes boiled potatoes are added. The mass is fermented either with leaven or yeast, and the dough is then baked in pans. The bread thus prepared is reputed to be light, wholesome, and agreeable to the palate.

2. Let a quarter of a pound of rice be boiled until it be quite soft; leave it to drain on the back part of a sieve, and, when cool, mix with it three quarters of a pound of wheat flour, a spoonful of yeast, and two ounces of salt. Let it stand for three hours to ferment, then knead it very thoroughly, and roll it in as much wheaten flour as will give to the exterior sufficient consistency to allow of its being conveniently deposited in the oven. After baking an hour and a quarter it will form a loaf of good white bread, weighing one pound fourteen ounces.

3. To one peck of wheat flour add half a peck of rice flour; let them be mixed and kneaded with salt, yeast, and warm water, in the usual manner. Divide the mass, when fermented and duly risen, into eight loaves, and bake them.

4. Boil a peck of rice until it becomes soft; let it stand all night in a pan, and it will be found greatly distended. Let a peck of potatoes be boiled, skinned, and mashed to a pulp. Knead them while hot with the rice and a peck of wheat flour; then add a sufficient quantity of yeast and salt, and leave the dough to ferment; the mass may be divided into loaves, and baked in the usual manner.

4250. *Bread made of Rice, Potatoes, and Wheat Flour.*—Boil some rice till it is soft, and let it remain some time afterward to swell. Boil an equal quantity of potatoes, peel and mash them, and, while hot, knead them up into dough with the rice, and the same quantity of wheat flour as of rice; add yeast and salt; let the dough rise, and bake in the usual way.

4251. *Although we have already described rice* as one of the materials of which bread is occasionally made, yet, as this is not the mode in which that substance is usually employed as food, its great importance demands a few farther remarks, which are chiefly extracted from the "Household Almanac and Year Book" for 1837. Rice constitutes the principal aliment of millions in India, who are supported by it in health and vigour; and many probably live and die without ever having tasted more substantial food. It is, perhaps, one of the cheapest aliments which can be obtained in this country; and though some persons imagine that it is not sufficiently nutritive, that opinion, upon trial, is found to be erroneous. Some objection is raised to its use on account of its insipidity, but this is easily corrected by the addition of a little spice, milk, suet, or sugar. With milk and sugar it makes excellent puddings. It can be employed as thickening in soups, or may be stewed with meat, bacon, or any other seasoning. In experiments made at the Foundling Hospital, in 1795, it was shown that rice can go much farther than flour for the same price, when made into puddings. Several circumstances, however, require to be attended to in cooking it. It is essential that it should be done till it is quite soft, yet, if brought to table by itself, that not a drop of water be seen with it.

4252. *Bread made of Oatmeal and Wheat.*—The following has been recommended as a good and economical bread: Add a peck of oatmeal to the same quantity of seconds flour, and half a peck of potatoes skinned and washed; knead it up into a dough with yeast, salt, and warm milk; make it up into loaves, and bake as usual. Oatmeal and rice may also be made together into bread.

4253. *Maize, or Indian-corn Bread.*—In North America maize is the principal corn, and bread made from it is extensively eaten in the United States, as well as in many parts of Europe. Meal from maize is made into unfermented cakes in the same manner as those from barley; but the late Mr. William Cobbett, who had considerable experience of its qualities, directs that a mixture should be made of one third maize and two thirds wheat or rye. "Set your sponge," he says, "with the wheat flour only. As soon as you have done that, put the water (warm water in cold weather, and cold in hot weather) to the corn flour, and mix the flour up with the water, and there let it be for the present. When the wheat sponge has risen and has fallen again, take the wetted-up corn flour and work it with the wheat sponge, and with the dry wheat flour that has been round the sponge. Let the whole remain fermenting together for about half an hour, and then make up the loaves and put them in the oven."

4254. *Buckwheat is capable of affording human food very wholesome and nutritious.* In many parts of the Continent it is so employed, as in France and Tuscany, mixed with barley and made into bread; in Germany it is used in puddings. This grain is covered with a hard, black, triangular husk, of which it is deprived by an operation previous to grinding. This is effected by high-drying the grain, either by the sun's rays or by the heat of a kiln, and afterward by running it slightly through the millstones. The husks are then blown away by a winnowing machine, and the grain is ground in the same manner as wheat. To convert it into bread, a gallon of water is boiled, and, by degrees, a peck of buckwheat flour is added, constantly stirring it to prevent lumps from forming, till the whole is formed into the consistence of a thick batter. Some salt is added, and the mass is boiled for an hour and a half. A quantity of this, sufficient for a cake, is then poured into an iron kettle hanging over the fire, in which it is baked, taking care to turn it frequently to prevent burning. An excellent mixed bread is made in England by the addition of a peck of wheat flour to the abovementioned quantity of buckwheat. After the latter has been made into batter and cooled down to blood heat, it may be poured into the trough containing the wheat flour and yeast; being there well kneaded, it should stand two hours to prove, divided into loaves, and baked rather longer in the oven than for wheat bread alone

The Tartars prepare an excellent food from buckwheat in a mode that might be applied upon occasion to other species of grain, where a mill and the other necessary apparatus cannot be had. They first steep the seed well in cold water, and then put it into sacks to drain for ten or twelve hours; after it has been thus swelled, it is well dried over a slow fire in iron pans, when the husks crack and split. The kernel, or flour, is then easily separated from the husks by beating it in a wooden mortar, and sifting separates the fine flour.

SECT. XI.—FARINACEOUS SUBSTANCES WHICH ARE USED IN VARIOUS PARTS OF THE WORLD INSTEAD OF BREAD, TOGETHER WITH OTHERS WHICH MIGHT BE OCCASIONALLY EMPLOYED IN TIMES OF SCARCITY.

4255. It may be useful to know all the plants, either in this country or abroad, which are capable of supplying us with farinaceous matter fit for food, with the view of introducing such of them as we have not noticed, thus increasing our resources against times of scarcity, which, although they rarely occur, are not altogether beyond our experience. It is likewise desirable to be acquainted with the various substitutes for bread which are employed in our colonies and in other parts of the world.

4256. *In many parts of the tropical regions*, the climate or the soil does not admit of the cultivation of corn of any kind; and in those places nature has supplied the inhabitants with other plants which afford a food nearly analogous to bread. Of these, the tribe of palms are some of the most useful of the tropical trees, affording not only an agreeable shade, but also an abundance of nutriment. The stem, or wood, consists of bundles of fibres, interspersed through a pithy substance that, in some species, is highly farinaceous, and which, when extracted by a simple process, constitutes our sago, arrow-root, and similar articles of food.

4257. *In the enumeration of some of the principal vegetables from which nature supplies man with abundance of food* almost ready prepared, in regions deprived of the cerealia, whether from the heat of the climate, or the aridity or rocky nature of the soil, we may perceive the bounty of Providence to the human race before it had extended, probably, to those parts of the earth where the cultivation of our faculties is more demanded. It would indeed be curious, but departing too far from our subject, to consider the numerous natural productions which, in the sultry regions, render effort less necessary, and thus, in fact, deprive man of the motives for progression. Safe under the shade of the banyan-tree, architecture could never have commenced, or if it had, the bamboo and the palm would have rendered the construction of a habitation a matter of little difficulty. Independently of delicious fruits, as the plantain and banana, numerous bread-trees present themselves; in Africa there is an excellent butter-tree, and Humboldt describes the cow-tree of Cumana, which, though growing upon a rock, affords, when its stem is pierced, a flow of delicious vegetable milk, which the natives collect and carry home to their children. Then, for furniture, they have barks to serve as baskets, leaves that fold up for umbrellas, and others that require little to transform them into hats, with numerous fibres ready made for thread and ropes. Little that is essential seems to be wanting for the support of man; yet is all this surpassed among more northern nations where nature has been less bountiful, through industry and art, the result of intellectual improvement.

4258. *Macaroni* is a favourite food in Italy, particularly among the Neapolitans, by whom it may be considered as their staff of life. It is prepared in the following manner, by a very simple process: The best wheat is made into a paste by the smallest quantity of water, and as this is too hard and consistent to be kneaded with the hand, the following contrivance is resorted to: A wooden pole, about fourteen feet long, is fastened at one end by a chain to a strong post fixed in the ground, so as to be moveable up and down like a lever, the paste being placed under one end. Two men take hold of the other end of this pole, and by elevating and depressing it alternately, and moving a little from side to side, they work the paste very thoroughly, the power of the lever being very great when acting in this manner. When the paste is sufficiently worked, it is put into a hollow cylindrical vessel, having its bottom of cast iron, and pierced with holes about the size of a goosequill, or of any size and form required. A piece of wood that exactly fits the inside of the cylinder is forced down upon the paste by means of a screw turned by two men, and in this manner it is forced through the holes in the form of the hollow tubes in which we see it. The macaroni is partially baked as it issues from these holes by a fire that is placed below the cylinder; and as it descends it is drawn away and hung on rods placed across the room, where in a few days it dries fit for use. The manufacture of macaroni appears to be sufficiently simple, and having been usually brought from Genoa and Naples in three different sizes, and also in thin plates, it was formerly sold at so high a price as to be seen only at the tables of the rich; but there appears no reason why it should not be made in this country; and, indeed, we are informed that a manufactory of it, as well as of vermicelli, has existed in White's Row, Spitalfields, ever since 1730. It is generally brought to table dressed with Parmesan cheese; it is likewise used in thickening soups, and in puddings. Since it is very wholesome and nutritive, it appears desirable that it should be brought more into general use.

4259. *Vermicelli* is a preparation very similar, and of Italian origin; it is made in the same way as the last, only to the paste are added cheese, yolk of eggs, sugar, and saffron. The name means little worms, from its form.

4260. *Semolina* is the heart of a kind of Italian wheat, called *grano duro*, remaining in granules, like coarse sand, that resist the action of the millstones, which are soft, blunt, and not set very close. It is imported for making the best vermicelli, and is also used in soups, and may be purchased at some of the Italian shops. It is called also *soojee*; and a still smaller kind, called semoletta, is sifted out of the other.

4261. *The polenta* of the Italians is made from maize, by roasting it when half ripe.

4262. *Fictitious sago*, salep, macaroni, vermicelli, semolina, and tapioca are manufactured from potato starch.

4263. *Rice boiled to a kind of paste*, and drawn out into threads, forms a transparent substance used to thicken soups, and is known by the name of *China lock soy*. There is a kind that is opaque, and which is less esteemed.

4264. *Sago* is the produce of the sago palm (*Sagus farinifera*, Linn.), which grows spontaneously in the East Indies, as well as in the islands of the Indian Ocean; in the latter, it supplies the principal farinaceous food of the inhabitants.

The part which affords the sago is the pith, and, to procure this, the body of the tree, when it is full grown, is sawn into pieces, and the raw sago cut out and put into a trough with water, in which it is well stirred to separate the flour from the filaments. This is now suffered to rest, and the flour, or meal, subsides to the bottom. The water is then poured off, and the wet flour laid upon wicker frames to dry. To form it into the round grains in which we have it, the sago, when moist, is passed through a colander, and rubbed into little balls like small shot, and then thoroughly dried. A single trunk of the tree will furnish 600 pounds of sago; and Mr. Crawfurd has calculated that in one acre of ground, 430 sago-trees can be planted, producing 120,500 pounds of sago. The trees require seven years to be fit to cut down. Our sago has sometimes been stated erroneously to be the produce of the *Cycas circinalis*, or *revoluta*, but that yielded by the cycas is inferior to the other kind. The best sago is of a slightly reddish hue, and readily dissolves in hot water to a jelly, but differs from wheat starch in being likewise soluble in cold water. A superior sort is imported from China which has a pearly lustre. Several other trees yield sago besides the above, but in less quantity.

4265. *Cassava.*—South America is the native region of a plant of this name (belonging to the tribe of Euphorbiaceæ), and the roots of which formerly afforded the chief sustenance to the Indians of that continent; it is still extensively used there, as well as in the West Indies.

There are two varieties of cassava: the *Jatropha Manihot*, or bitter cassava, and the *Jatropha Janipha*, the sweet cassava. They nearly resemble each other, and both are used as food. The first, in its natual state, is so highly poisonous, that the Indians employed its juice for poisoning their arrows; the second is not at all hurtful. The roots of the bitter cassava are nearly of the shape and size of parsnips; and to prepare them they are grated, and the pulp is subjected to pressure, to deprive it of its poisonous juice, which is of a milky colour: by allowing this to rest, a white starch subsides, which is separated from the clear juice, and reserved for use as food. What remains after pressure consists of the same kind of starch, mixed with the woody or fibrous part of the roots; when this is dried by exposure to the heat of a fire, it is pounded and sifted, to separate the fibrous matter from the starch. The latter is made into dough, which is formed into cakes that are afterward baked. It is supposed that what may remain of the poisonous juice in the starch is volatilized by the heat employed. The original inhabitants of America had employed this process for the preparation of cassava; and it is singular that they should have found out the means of separating an excellent food from a substance known to be a malignant poison. The *sweet cassava plant*, of which bread is also made, is free from any noxious property; its stalks are green, whereas those of the bitter cassava are rather of a purplish hue.

4266. Cassava bread, though not relished by those accustomed to wheaten bread, yet is in such repute with some Creole families who have settled in Europe, that they have sometimes been at considerable trouble and expense to procure it.

4267. *Tapioca* is made from the finest part of the farinaceous pith of *Jatropha Manihot*, or cassava-tree, by washing the root and preparing a fecula or starch from it, which, when dried, is sprinkled with a little water, and steamed, so as to form irregular masses, when dried in the sun, or on plates of hot iron; these are afterward broken into the small grains, in which form we have it. A considerable quantity is imported from Brazil, and it is also made in the East Indies. It is extremely nutritious, and forms an excellent food for children, and persons whose powers of digestion are weak.

"No amylaceous substance," Dr. Christison observes, "is so much relished by infants about the time of weaning; and in them it is less apt to become sour during digestion than any other farinaceous food, even arrow-root not excepted."

4268. *Arrow-root* is a well-known, very nutritious fecula, obtained from the roots of the *Maranta arundinacea*, or starch plant, a perennial cultivated in the East and West Indies. Its name is derived from another plant with which it was once confounded, now called Apinia galanga, the root of which the Indians used as an antidote to the poison of arrows. The roots are dug up when they are about a year old; and, after being well washed, they are beaten to a pulp, which is again washed in water to separate all the fibrous part; after being passed through a sieve, the starch is suffered to settle, when the water is drawn off. The white sediment of starch is again washed with water; and, when it is dried by the heat of the sun, it forms the pure arrow-root. The best arrow-root we have is from Antigua, Jamaica, and Bermuda; but a great deal of what is sold in London is adulterated with potato starch, which, though a substance not very different, has not precisely the same properties. Arrow-root, like every kind of starch, boils to a jelly, but it differs from potato starch in this respect: the jelly formed with arrow-root will remain firm for three or four days without turning thin and sour, whereas the jelly from potato flour, in the course of twelve hours, becomes as thin as milk, and acescent; hence it is not so well calculated for food, and particularly for children. It is, therefore, very important to have this useful article genuine when a strengthening food is required: potato flour, though inferior, may, on occasion, form a cheap substitute.

4269. *Salep* is considered to be a very nutritious substance. It consists almost entirely of a peculiar vegetable principle called *bassorin*, with a small quantity of starch and gum. The name of bassorin is derived from gum bassora, in which Vauquelin first discovered this priniciple, which is likewise found in gum tragacanth. Salep is imported from the East Indies, Turkey, Syria, and Persia, where it forms a considerable part of the food of the inhabitants, boiled, or in soup. It is said that an ounce a day is sufficient to sustain a man; hence, from its portability, it is very useful to travellers over desert regions. It is prepared from the roots of different species of orchis, especially the *orchis mascula*, a tropical plant, though some is manufactured in Europe. The bulbous roots of these plants are deprived of their cuticle, and baked in an oven for ten or twelve minutes, which gives them a semi-transparency: they are then dried in a moderate heat.

Salep is brought to this country in oval pieces, of a yellowish-white colour, somewhat clear and pellucid, very hard, and almost horny; of little or no smell, in taste like gum tragacanth. It is not easily pulverized. The powder, dissolved in water, forms a jelly.

4270. *The orchis*, or *salep plant*, grows plentifully wild in moist meadows in some parts of Britain and Ireland, particularly in Gloucestershire, and is also cultivated, but not to any extent. It has been proposed to make salep from it; and it is proper that it should be pointed out, as a resource to the poor in times of distress. The preparation of salep has been described in "Philosophical Transactions," vol. lix. The bulb, or tuberous root, is to be washed in water, and the fine brown skin which covers it is to be separated by means of a small brush, or by dipping the root in hot water, and rubbing it with a coarse linen cloth. The bulbs are then to be dried upon a tin plate, by placing it in an oven for six or ten minutes, in which time they will have lost their milky whiteness, and they will then become transparent like horn. They are afterward dried in the air, which will take several days; or a gentle heat may be used, which will effect the same in a few hours. Reduced into powder, they soften and dissolve, in boiling water, into a kind of mucilage, which may be diluted for use with a large quantity of water or milk, and comes very near to what is made from the salep brought from Turkey.

Dr. Percival, in his "Medical and Experimental Essays," mentions that a mixture of mucilage of salep with flour makes an excellent bread.

4271. *Portland sago* is so called from the Isle of Portland, where the substance is manufactured from the roots of the common wake robin, *arum maculatum*, which grows there in great abundance. These roots are full of farina; but, in their natural state, they are so acrid that, if the juice be applied to the skin, it will raise blisters; it appears to be very analogous to the poison of the cassava root; and, like that, is so volatile that, when heat is applied by roasting or boiling, it is dissipated, and the roots rendered perfectly harmless. When, after this, they are dried and pounded, they afford a starchy matter very much resembling the Indian arrow-root; in consequence of which, it is sometimes called *English arrow-root*.

4272. *Tous les mois* is the French name for a new aliment, prepared from the pith in the roots of the canica coccinea, a plant which flowers every month, whence it has received its appellation. It is stated by Dr. Waterton, of St. Kitt's, to differ in some respects from arrow-root, though extremely analogous to it, and applied to the same uses. It is said not to be apt to sour upon the stomach, and to be well calculated for invalids and children. It is imported into London, and sold in canisters at 2*s*. and 4*s*. each.

4273. *Tacca.*—This is the root of a plant of that name, which, when mashed and prepared, affords food to the natives of the South Sea Islands and the Malays. The roots are something like yams, but in their natural state are bitter and acrid; they are rasped very fine, and steeped in several waters. The farinaceous matter thus prepared is both palatable and nutritious, and is made into cakes and loaves, which some prefer to sago bread. The leaf-stalks boiled are used as food in China.

4274. *Bread Nut* (*Brosimum Alicastrum*).—These nuts abound with farinaceous matter, together with much gummy substance; they form a very nutritious food, and are eaten by the negroes boiled, or roasted with meat instead of bread.

4275. *The celebrated Lotus*, the *Zizyphus Lotus*, is eaten in Barbary and other parts of Africa, and the following account of it occurs in "Burnett's Outlines of Botany." "Dr. Shaw says this fruit is common in the deserts and other parts of Barbary, and is still in great repute, and sold in the markets all over the southern districts, and cattle as well as men are fed upon it. Park states that he found the lotus abundant in all the countries of Africa he traversed, but in the greatest plenty in the kingdoms of Kaarta, Ludamar, and the northern parts of Bambara. The natives, he says, convert the fruit into a sort of bread by exposing it some days to the sun, and afterward pounding it gently in a mortar until the farinaceous part is separated from the stone; this meal is then mixed with a little water and made into cakes, which, when dried in the sun, resemble in colour and flavour the sweetest gingerbread. The stones are afterward put into a vessel of water, and shaken about, so as to separate all the farina that adheres to them. An agreeable taste is thus given to the liquid, which, by the addition of a little pounded millet, is made into a kind of gruel called *fondi*, and this, for several months in the year, forms the common breakfast of the majority of the people in many parts of Ludamar. The fruit, when dried, is laid by for winter use; a sort of wine is also made from it by expression and mixing the juice with water; it is a pleasant drink, but will not keep many days. The people who lived upon the lotus were denominated Lothophagi in the time of Homer."

4276. *Arracacha.*—A farinaceous root about the size of a cow's horn, which grows abundantly on the plains of Bagota, and which has lately been brought to England. A few which are planted near Plymouth are said to thrive well, and may prove in time a valuable addition to our farinaceous vegetables.

4277. *Acorn Bread.*—Take ripe acorns, deprive them of their skins, and beat them into a paste; steep them in water for a night, and then press them dry, which will take out their astringent quality; then dry the mass, and reduce it to powder, to be kept as flour or meal when wanted. Form this into dough, knead it, and make it into thin cakes, which may be baked on an iron plate or the embers. This has been used, but we cannot recommend it.

4278. *The whole of the bran may be used in bread made of wheat.* In the Reports for bettering the Condition of the Poor, we find an account by Sir Thomas Bernard of the use of bran in bread, which was recommended in a time of scarcity: "Take seven pounds of bran and pollard, and fourteen quarts of water; boil the whole very gently over a slow fire; stir it frequently to prevent burning. After two hours boiling it will acquire the consistence of a custard pudding; then put it into a cloth, and twist it till the liquor is squeezed out. Mix a quart of this with three pints of yeast, and set the sponge for twenty-eight pounds of flour. The bran and pollard, which, when the liquor has been squeezed out, is above four times its original weight before it was boiled, is then to be set near the fire, in order that it may be kept warm. In about two hours the sponge will have sufficiently risen, upon which the bran and pollard (then lukewarm, but not hot, and into which is to be sprinkled about half a pound of salt) should be mixed with flour, and the whole kneaded up very well together with a quart of the bran liquor, and it should then be baked for two hours and a quarter in a common oven. The produce, weighed when cold, will be half as much again as the same quantity of flour would produce in the common way without the addition of bran. Most of the objections to the use of bran appear to be founded on a presumption that no mode of preparation will make any difference in the degree of nutriment to be derived from it as a food. Though the subject is yet but little understood, we have gone far enough to ascertain the fact that, in most kinds of grain, some increase of the ordinary nutritive power may be produced by culinary process; the very making of bread affords an example of this increase. In rice it is very great; and in barley meal, particularly when used in soup, its increased power of nutriment may be extended to a surprising degree, as it is now well known that rice, when increased by water to a solid substance of five times its original weight, or, by the addition of milk, to eight times what it originally weighed, is converted from a hard, indigestible grain into a wholesome, nourishing food.

4279. *The fibrous part of potatoes, left after the starch has been separated*, is stated by Sir John Sinclair to be not only a valuable article of food for horses and cattle, but that it may be advantageously employed in bread upon occasion. Mr. Jefcoat, of Gateshead, near Newcastle-upon-Tyne, has proved that 21 lbs. of wheaten flour, kneaded with 12 lbs. of the fibre of potatoes, will produce, when well baked, 38 lbs. 8 oz. of excellent bread, which, allowing that a stone of flour produces at the rate of 18 lbs. of bread, is an increase of 11½ lbs. of bread from 12 lbs. of fibre. His mode of preparing the fibre is as follows: After washing it in two waters, he places it for about an hour upon a sieve to drain; then he adds, without its being boiled, the usual quantity of yeast; and after it has stood for about an hour, he works in the 21 lbs. of wheaten flour. It requires very little addition of water, but rather time to rise, preparatory to its being placed in the oven. The bread thus prepared continues equally good for several days. This potato fibre may also be used with barley or oatmeal, and is an excellent ingredient in a pudding with milk and butter, and either with or without eggs and other ingredients.

4280. *Lichen Islandicus*, or Iceland moss. The lichens form a remarkable class of plants that live in the most barren situations in the most northern parts of the world, where nature refuses any description of corn, growing even on bare rocks. They have no roots, but adhere by a kind of claws, and are nourished by absorption from the atmosphere. The Lichen Islandicus, so named from existing in vast abundance in Iceland, on the northwest coast of which scarcely any other vegetable is to be seen, is now called by botanists *Cetraria* islandicus, and had formerly received the name of *Reindeer moss*, as supplying the only food which these animals can procure in the winter season. The appellation moss is improper, as it is really a lichen.

Notwithstanding its mode of growth, it is an extremely nutritious substance, as may be seen from the following analysis by Berzelius: Starch, 44·6; lignin, 36·6; green wax, 7·0; bitter principle, 3·6; acidulous tartrate of potash and lime, 3·0; extractive, 1·9; traces of gallic acid. With the Icelanders it constitutes a very important article of aliment, and is collected by them during the summer months. The lichen has an outer skin covering a green resinous substance; and the remainder of the plant consists chiefly of fecula, or a kind of gummy, soluble matter, and of a fibrous matter, on which water does not act. The plant has a natural bitterness and astringency; and to take this off, it is scalded two or three times with boiling water, which causes the skin to crack, swell, and peel off. It is then steeped for an hour or two in cold water to extract the bitter principle, and boiled for an hour or two in milk till the liquor acquires a gummy or gelatinous consistence. When cold, this is a jelly like blanc-mange, and it is eaten with milk or cream, with which it makes a very palatable dish. The Icelanders also make it into a kind of bread; or it is powdered or ground, and the meal made into porridge, gruel, or broth, or baked as cakes: these Dr. Henderson describes as not only wholesome and nutritious, but extremely palatable.

This useful plant is not confined to Iceland, but grows all over the north of Europe, and is found on the Pentland hills, the mountain of Ben Lomond, and many other parts of the Highlands of Scotland, but it does not grow to so large a size there as in Iceland. It is also found on many of the lofty mountains of Europe, where the temperature is low, as the Alps, Pyrenees, Jura, &c. From its esculent qualities, its use has been recommended in times of scarcity. If it is boiled for a quarter of an hour after the bitter principle is extracted, it may be dried, and will keep for any length of time.

It is, however, not sufficiently plentiful in this country to be much regarded as an article of food; but it is thought to have some tonic power, and to be proper for convalescents. Dr. A. T. Thomson observes that this quality depends on the bitter principle contained in it; consequently, when employed as a tonic, the bitter should not be wholly removed.

4281. *The starch procured from the horse-chestnut* has been employed successfully in Germany for many of the purposes of flour.

4282. *Bread from the Bark of the Pine.*—From the civilized state in which we now live, we can form but faint ideas of the necessitous situation under which many of the inhabitants of the globe exist, and in comparison of whom our poorest cottagers may be considered in a state of ease. Von Bush informs us that in the rigorous and unfertile climates of Norway and Lapland necessity obliges the inhabitants to make use of the inner bark of the common Scotch fir (*Pinus sylvestris*) for food. In the spring season they cut down the older trees, and, stripping off the bark, collect the soft, white, succulent interior part, which in the early time of the year has a sweet, milky juice in it, and is the new layer of wood in an incipient state. When they have occasion to use it, they dry this at the fire, or bake it in an oven, till it becomes brittle; then beat it and grind it into meal, and after steeping the farinaceous part or flour in warm water to take off the resinous taste, they mix it with a small portion of oats or moss, and make it into thin cakes about an inch thick, which are baked for use. The poor inhabitants are sometimes constrained to live upon this disagreeable food for a great part of the year. We learn from the same authority that "in summer the Laplanders scarcely eat anything but fish from the fresh-water lakes, and drink with great eagerness the water in which the fish has been boiled. In winter they must put up with dried fish and the innermost bark of the fir, which they strip off in summer, divide it in long strips, and hang them in their dwellings to dry for winter stores. When used, these strips of bark are minced in small pieces along with reindeer tallow, and boiled together for several hours with water, till they form a thick broth." Dr. Prout suggests, with respect to this process, that, during the long boiling, the lignin or woody fibre may, perhaps, combine with the water so as to form a kind of starch, which is soluble in the stomach; but the precise nature of the change is not yet understood.

The young shoots of the fir stripped of their leaves just as they begin to appear in the spring are sought for with avidity by the children, and are very wholesome, forming an agreeable salad; these are also stored in winter for the reindeer. In the same countries, also, they dry the root of the water-dragon (*Culla palustris*), grind it to flour, and mix it with the above. The inner bark of the elm and other trees has been employed in the same manner.

4283. *The seeds of the stone pine*, being farinaceous, are eaten in some parts bordering the Mediterranean, and likewise those of the gigantic pine discovered by Douglas in the west part of North America. The inhabitants of Australia likewise bruise and eat the seeds of the screw pine (*Pandanus spiralis*, Brown) and of several cone-bearing pines, but these do not form a very nutritive food.

4284. *The roots of various species of fern* are used as food in different parts of the world. Those of the *Pteris*, the common fern of this country, are ground to powder, mixed with barley meal, and boiled by the poor inhabitants of the Canary Islands; but it is a very coarse food. Another kind, the Cyathea, is much superior, has soft and pulpy roots, and affording a substance not unlike sago, is eaten by the New-Zealanders. The *Pteris esculenta* of Australia, which much resembles the common English fern, has roots which contain a good deal of farinaceous matter; but though these form, in some places, the principal food of the natives, they are very disagreeable, being mixed with much woody matter. A remarkable fern (*Angiopteris erecta*) grows in the Society Islands, the roots of which weigh fourteen pounds, and are used by the natives as food.

4285. *Bread made from Wood.*—Professor Autenrieth, of Tubingen, has shown, by a series of careful experiments, that it is possible to make a palatable and nutritious bread from the dry, ligneous part of wood by proper management. The following is his process, as we find it stated by Dr. Prout in the Philosophical Transactions, 1827: "In the first place, everything that was soluble in water was removed by frequent maceration and boiling. The wood was then reduced to a minute state of division, that is to say, not merely into fine fibres, but actual powder; and after being repeatedly subjected to the heat of an oven, was ground in the manner of corn. Wood thus prepared, according to the author, acquires the taste and smell of corn flour. It is, however, never very white, but always of a yellowish colour. It also agrees with corn flour in this respect, that it does not ferment without the addition of leaven, and in this case some leaven of corn flour is found to answer best. With this it makes a perfectly uniform and spongy bread, and when it is thoroughly baked, and has much crust, it has a much better taste of bread than what is in times of scarcity prepared from the bran and husks of corn. Wood flour, also, boiled in water, forms a thick, tough, trembling jelly, like that of wheat starch, and which is very nutritious."

The following details respecting this extraordinary process are added in the Quarterly Review: "To make wood flour in perfection, according to Professor Autenrieth, the wood, after being thoroughly stripped of its bark, is to be sawed transversely into disks of about an inch in diameter; the sawdust is to be preserved, and the disks are to be beaten to fibres in a pounding-mill. The fibres and sawdust, mixed together, are next to be deprived of everything harsh and bitter which is soluble in water by boiling them where fuel is abundant, or by subjecting them for a longer time to the action of cold water, which is easily done by enclosing them in a strong sack which they only half fill, and beating the sack with a stick or treading with the feet in a rivulet. The whole is then to be completely dried, either in the sun or by the fire, and repeatedly ground in a flour-mill. The ground wood is next baked into small flat cakes, with water rendered slightly mucilaginous by the addition of some decoction of linseed, mallow stalks and leaves, lime-tree bark, or any other such substance. Professor Autenrieth prefers marsh-mallow roots, of which one ounce renders eighteen quarts of water sufficiently mucilaginous, and these serve to form four pounds and a half of wood flour into cakes. These cakes are baked until they are brown on the surface. After this they are broken to pieces and again ground, until the flour pass through a fine bolting-cloth; and upon the fineness of the flour its fitness to make bread depends. The flour of a *hard wood*, such as beech, requires the process of baking and grinding to be repeated. Wood flour does not ferment so readily as wheaten flour, but the professor found fifteen pounds of birch-wood flour, with three pounds of sour wheaten leaven, and two pounds of wheat flour, mixed up with eight measures of new milk, yielded thirty-six pounds of very good bread. Professor Autenrieth tried the nutritive properties of wood flour, in the first instance, upon a young dog; afterward he fed two pigs upon it; and then taking courage from the success of the experiment, he attacked it himself. His family party, he says, ate it in the form of gruels or soup, dumplings, and pancakes, all made with as little of any ingredient as possible, and found them palatable and quite wholesome." This account, were it not so well authenticated, might have the air of a romance, and it still remains to be shown how far the fact may be available for useful purposes in general; in the mean time, it adds to the stock of our knowledge on the subject of food.

BOOK X.

ON THE PRESERVATION OF FOOD.

CHAPTER I.

INTRODUCTION.—GENERAL OBSERVATIONS.

4286. *All animal and vegetable substances being liable to change*, so as to be at least unfit for food, their perishable nature, together with the unavoidable irregularity in their production, has imposed upon mankind the necessity of storing up the superabundance of one time to meet the exigencies of another. It has, therefore, become an object of great importance to ascertain the best method of *preserving* the various substances suitable for food as nearly as possible in their original state, or, at least, in some condition in which their nutritive properties may be, as much as possible, retained. But for the art of preserving food, mankind would at times be subjected to great deprivations; and to mariners, in particular, every method of preserving articles of diet in a wholesome and nutritive state must present itself under a very striking point of view.

When we hear of beef, fruit, milk, and other articles of nutriment eaten quite fresh after having travelled round the globe, and when we consider the simplicity of the means by which this has been effected, we must admit the value of those sciences to which this almost miraculous preservation is owing.

4287. Thus the methods of preserving food for a shorter or a longer period of time are not only deserving of attention in domestic economy, but are highly important in a national point of view. We shall begin by adverting to the chemical history of the substances to be preserved, the nature of which has been already described in Book VII.

4288. *While the living principle exists* in a healthy state in animals and vegetables their elementary constituents cannot separate, and no decomposition can take place; but no sooner is life extinct than an alteration commences, and those elementary substances which we have described as composing the whole animal and vegetable kingdom, and which are held together by the laws of organic life, have a tendency, when deprived of this bond, to separate from each other, and to enter into new combinations. This is a law of nature. Organic bodies come into existence, live their allotted time, and die. If nothing retards the usual course of things, they then pass into other states, and the tangible substances of which they consist are made to form the corporeal part of other living beings. Man, whose present existence demands the use of some portion of matter which is in the act of passing from one state to another, contrives various methods of arresting it in its progress to decay, and rendering it in the mean time subservient to his wants.

4289. *The inevitable change to which dead organic matter is liable is called fermentation*, of which we pointed out, in a former part of this work, that there are several kinds, the vinous, the acetous, and the putrefactive. By the first two, useful products are obtained; but the last is that complete change, termed decomposition, by which the substance is entirely resolved into the inanimate materials of which it had been originally composed, and the greater part of which are finally, if left to themselves, dissipated in the atmosphere in the form of offensive and noxious gases. These changes do not take place precisely in the same manner in animal as in vegetable substances. Although vegetables generally go through more than one of the stages just mentioned, and sometimes through all three, yet the flesh of animals can pass at once into the putrefactive state.

4290. *We have previously stated that animal bodies differ from vegetables in their composition*: the former always have a large quantity of nitrogen as one of their elementary principles, whereas nitrogen enters in a small proportion as a constituent in vegetables.

When animal bodies undergo the putrefactive fermentation, or putrefaction, their elements, oxygen, hydrogen, nitrogen, and carbon, separate from each other, and combine again in the following manner: The carbon absorbs oxygen from the atmosphere, and forms carbonic acid; one portion of the hydrogen forms water with the oxygen; an other portion, uniting with the nitrogen, composes ammonia ; of the rest of the hydrogen some part combines with the carbon, producing carburetted hydrogen gas ; and the remainder unites with some phosphorus and sulphur which animal bodies contain, thus giving rise respectively to phosphuretted and sulphuretted hydrogen gases, which are in part the cause of the nauseous smell evolved by substances that putrefy, although this does not entirely account for the remarkable fetor which is diffused, an effect which is not perfectly understood.

4291. *We observed that vegetable matter*, under favourable circumstances, can go through a series of changes before they arrive at the putrefactive state ; nevertheless, there are some cases where vegetables decompose without experiencing all these. Sometimes they pass into the acetous state without perceptibly going into the vinous, and sometimes the putrefactive alone takes place, as in the case of mushrooms. Vegetables which contain no nitrogen, particularly the ligneous parts, decompose much more slowly than animal matter. The juices which plants contain first enter into the acetous fermentation, and the acid thus generated destroys the cohesion of the ligneous fibre, and reduces the whole to a pulpy state ; but there is very little of that smell so remarkable in animal putrefaction, because the whole of the elementary principles necessary to form the offensive gases seldom exist in vegetables. When vegetables putrefy, their oxygen and part of their hydrogen unite and form water, while another part of their hydrogen combines with carbon, and forms carburetted hydrogen ; but the chief part of the carbon remains in one of the simplest forms of this element, and gives the black colour so prevalent in a rich soil produced chiefly by the decay of plants that have grown there.

4292. *In dead animal bodies*, it is the albumen that first begins the putridity, and serves as a ferment to the rest ; and those plants which contain much vegetable albumen are most apt to become putrid, as mushrooms, cabbages, &c.

4293. The production of ammonia has been generally supposed to distinguish the putrefaction of animal from that of vegetable bodies ; but although this is generally the case, there are exceptions. Such vegetables as contain nitrogen, as the gluten of wheat, also generate ammonia abundantly.

4294. *In the putrefactive fermentation certain conditions are necessary*, as is the case in the vinous and acetous, viz. : 1, a certain degree of heat ; 2, a certain degree of moisture. If we deprive animal and vegetable substances of either of these conditions, no change can take place. 3. The access of air, likewise, though not absolutely necessary, remarkably accelerates it. It is upon these principles that some of the methods of preserving food are founded. The process of putrefaction agrees also with the other stages of fermentation in this respect, that a small quantity of animal substance in this state will inoculate others with which it is in contact, and occasion them also to putrefy ; even their effluvia will sometimes have this effect.

4295. *We shall divide this subject into two parts.* The first will relate to those precautions which are necessary to preserve meat and vegetables for a short time in a perfectly fresh state previous to their being subjected to the culinary art ; and the second will describe the modes of preserving from decay the various species of food which are required to be kept as store for a considerable length of time. But as the difference in the nature of animal and vegetable food demands different modes of treatment, we shall consider each of these classes separately.

CHAPTER II.

PRECAUTIONS TO BE USED IN KEEPING ANIMAL FOOD FOR A SHORT TIME PREVIOUSLY TO ITS BEING COOKED.

4296. *In consequence of the changes to which we have alluded*, it might be supposed desirable that all animal substances used as food should be dressed as soon as life has been destroyed. This, however, is true only of some kinds. The flesh of some animals which have been just killed is at first tough and difficult to digest ; a fact well known to all butchers and cooks, who are not ignorant that the keeping of it for a long or short time, according to circumstances, previously to its being dressed, renders it more tender, palatable, and easy of digestion. Our object is to point out the principle upon which this depends.

The fleshy fibre, or muscular part of living animals, is endued with a property called *irritability*, and this does not cease the instant that life becomes extinct, but continues for a short time after death. The hearts of many animals continue to beat after being separated from the body, and a muscle cut from a living creature trembles and palpitates for some short time afterward. The bodies of animals that are slaughtered cool gradually, and when they are quite cold, and irritability has ceased, *the muscles begin to contract and grow rigid ;* first those of the trunk, and then of the limbs. In whatever attitude the limbs are placed at the commencement of rigidity, they continue, and hence butchers take care to dress the carcasses of animals properly while they are in a supple state.

4297. *While this rigidity continues, meat is tough*, and can scarcely be made tender by any process of cookery, except by being long stewed, or being made into soup, for which it is quite proper; but if boiled or roasted in this tough state, it resists in a considerable degree the action of the gastric juice, or, in other words, it is hard to digest. If meat be kept for a few days or less, according to the weather and climate, this rigidity ceases, the flesh becomes softer, and, before long, those changes commence, which, if suffered to go on, would terminate in putrefaction. Now the moment when the meat is in the fittest state to be dressed, as being the most tender, is just *before* the last change commences; for it is the nature of the decomposing or putrefactive process to loosen the fibres, and dispose the muscular part to be easily acted upon by the digestive organs. It is upon this principle that animals killed by electricity and cooked immediately are found to be tender, because the electric fluid has destroyed entirely the irritability of the nervous system.

4298. *But the length of time that meat ought to be kept* after it is killed depends upon the climate, the season of the year, the weather, and the temperature, moisture, and ventilation of the place where it is kept, as likewise the particular kind of animal. In very warm climates, meat will not keep above four or five hours, and is therefore used in a more recent state than in cold countries. With us it is sooner ready in summer than in winter; and in some animals, as in venison and game, this change is permitted to show stronger symptoms than in other kinds of meat before it is considered as fit for the spit. But although it is proper to hang up meat for some time in the air till its fibres have lost some degree of their rigidity, yet it must be clearly understood that if it be kept so long as to lose its natural sweetness, and to exhibit symptoms of putrescence, it becomes as detrimental to health as it is disagreeable to the smell and taste. Much experience and attention to various circumstances are necessary to determine exactly how long any particular joints ought to hang up in order that they may be ready against a certain day; and much of the success of the cook will depend upon hitting this point with precision, by using the necessary precautions. In warm weather, the change from the rigid state towards putrefaction proceeds often too rapidly, and then it requires to be checked. But a moderate reduction of temperature may be all that is required.

Meat should, accordingly, be always kept in the most cool and shaded places, as a degree of temperature very little below that of the atmosphere, even 10°, is of great use in warm weather.

In summer it is difficult to get meat that is not either tough or tainted, as the butcher runs great risk in keeping it sufficiently long, and is therefore glad to sell it as soon as he can. The best mode, therefore, is to buy joints as fresh as possible, and to hang them up in the larder, where the manner of proceeding must be founded upon the principles which have been alluded to.

The due degree of *itineration*, or tenderness of meat, may be partly ascertained by the way in which it yields to the pressure of the finger, and by its opposing little resistance in attempting to bend the joint; fortunately, the slightest degree of change beyond that can be detected by the odour.

4299. *Where a regular larder is desired, its construction should be carefully attended to.* It should be cool and dry, should have good ventilation by windows on opposite sides, which ought to be covered with wire cloth to admit the air, but not the flies, which lay their eggs in the meat, and occasion it to be what the cooks call *fly-blown;* and from these eggs, if suffered to remain, maggots will be produced. Meat should be carefully examined every day in summer, wiped dry, and such bits as are beginning or seem liable to taint, particularly kernels, should be removed. It may be kept for several days more in hot weather than it otherwise would, by wrapping round it a linen cloth moistened with vinegar, or equal parts of vinegar and water; the acid vapour keeps off the flies, and the moisture occasions cold by evaporation. The wood vinegar, or pure pyroligneous acid, may be used for this purpose. Charcoal bruised to powder has also the property of preventing meat from spoiling for some time, and, in some cases, is useful; it is important that it should be fresh made, or at least heated red hot and cooled again, and spread entirely over the meat. So strong is the antiseptic power of charcoal, that meat, when but slightly tainted, may be recovered by boiling it for some minutes with some pieces of this material fresh burned.

4300. *To preserve fish quite fresh for a short time* requires even more care than meat. They should be kept in a very cool place, an ice-house if possible; but if that cannot be had, they should be laid upon a stone floor or shelf, and dipped in cold salt and water every night and morning. If it is necessary to keep them a few days longer, this may be done by immersing them in a pickle composed of equal quantities of common vinegar, small beer, and water.

4301. *Succulent or soft vegetables*, such as cabbages, when just gathered, quickly lose their natural juices by evaporation from the leaves, which soon become flaccid, and in his state they are not only disagreeable to the eye, but deteriorated with respect to their nutritious properties. Every care should, therefore, be taken to preserve them in their full and plump state previous to their being dressed. As heat is the cause of the loss of their juices, a cool, shady, and damp place is proper to keep them in. A cool cellar, with the floor paved with stone, is the most proper place, except there be an ice-house or a room attached to it, which is still better.

They should not be kept in water, as that dissolves and destroys some of their juices, and injures their flavour; and the best method of refreshing them is to cut off a portion of the stem, and set the cut part in water, of which the vegetable will then absorb a good deal to supply the leaves and make up for the evaporation. They should not be laid together in heaps, since this is apt to generate heat and fermentation, as is often the case with vegetables brought up from the country to market, when they are seen to steam and sweat, as it is called, in which state they are far from being wholesome. In the "Practical Directions to the Cook," Book XII., farther particulars relating to the business of the larder will be found.

CHAPTER III.

PRESERVATION OF ANIMAL FOOD FOR A LONG TIME.

4302. *The various modes of preserving animal food as store* for a considerable period of time may be reduced to the following: 1. Preserving by drying; 2, by cold; 3, by salting, and by sugar; 4, by smoking; 5, by vinegar; 6, by M. Appert's method of parboiling and excluding the air; 7, by potting; 8, by alcohol. Sometimes one of these methods is employed singly, and sometimes several in conjunction.

4303. *Substances that prevent the putrefaction* of animal and vegetable bodies are termed *antiseptics;* the principal of which are, common salt, nitre, vinegar, spices, and sugar. These operate partly by inducing a change in the fibres, and partly by rendering the aqueous constituents unsusceptible of decomposition.

SECT. I.—PRESERVATION OF ANIMAL FOOD BY DRYING.

4304. *Moisture being one of the essential conditions of the decomposition of animal substances,* their complete desiccation is one of the means of preventing their decay, and is employed as a mode of preserving them as food for a long period. Every one knows that common glue will dry quite hard, and will keep in this manner for any length of time; the same is the case with white of egg if it be spread thin, one layer being dried upon another. Now, both these substances, consisting the one of gelatin and the other of albumen, are constituents of flesh; and fibrin, or the fleshy fibre, dries equally well, and in that state is not liable to putrefaction. Gelatin, after being hardened by drying, is easily softened again, and brought into the gelatinous state by hot water; but if albumen be thoroughly coagulated by boiling water, it cannot be softened again; nevertheless, albumen can be dried without coagulating in a heat of 140°, and may then be redissolved in cold water with its valuable properties unaltered. Meat dried to be preserved for cooking must not, therefore, be exposed to too high a degree of heat, other wise it would become insoluble.

4305. *Remarkable instances of the power which drying has in preserving* flesh may be observed in those parts of the earth where there are sandy deserts, and where rain seldom falls; the air that blows over these is rendered dry, and possessing a great affinity for moisture, greedily attracts it from all substances with which it comes into contact. Buried in these deserts, the bodies of travellers and of camels that have been arrested and overwhelmed by the drifting sand have been found preserved from time immemorial, the flesh having been totally deprived of all moisture, and perfectly dried. While they continue in that state they are not liable to change. Such effects are never known in Britain, the winds being well saturated with moisture before they can reach our shores.

4306. *The North American Indians, in the fur countries, prepare the flesh* of the bison, buffalo, and deer merely by drying, according to the account given by Mr. Hearne, in his "Journal to the Northern Ocean," who found it to be excellent food. This preparation is called "pemmican." It is stated to be quite essential to travellers in those countries, and is thus described by Captain Back, who travelled with Sir John Franklin:

"While meat remains in a thick piece, it is impossible to get the middle dried before putrefaction commences; but if the meat be cut into slices, its desiccation may be easily effected. The fleshy parts of the hind quarters are cut into very thin slices, dried in the sun or before the fire, and pounded. Two parts of the pounded meat are then mixed with one of melted fat, and packed into a bag formed of the hide of the animal. A bag weighing ninety pounds is called a *taureau* by the Canadian voyageurs; and, in fact, only one bag of pemmican is generally made from each bison cow. Two pounds of this kind of food are sufficient for the daily support of a labouring man, though, when the voyageurs first commence upon pemmican, they will each consume three pounds, or more. In the spring, they generally boil the young shoots of the *Epilobium angustifolium* along with it; and some Scotchmen in the service of the Hudson's Bay Company add flour or oatmeal, thus rendering it more palatable. The best pemmican is made of finely-pounded meat, mixed with marrow, and farther improved by the addition of dried berries or currants. If kept from the air, it may be preserved sound for several years, and being very portable, it might be used with great advantage in provisioning troops that have to make forced marches. It may be eaten raw, or mixed with a little water, and boiled; and although not much rel wished by those who taste it for the first time, the *voyageur*, with a single addition of the luxury of tea, requires nothing else for breakfast, dinner, or supper."—*Back's Journal.*

4307. *The Moors of Africa preserve meat in the following manner:* They cut into thin slices beef, mutton, or camel's flesh, and after salting them well, suffer them to lie in the pickle twenty-four hours. The meat is then removed from the tubs or jars, and put into others filled with fresh water; and when it has remained there a night, it is taken out, and hung on ropes to dry in the sun and air. When thoroughly dried and hard, it is cut into pieces two or three inches long, and thrown into a pan, or caldron, which is kept ready with boiled oil and suet sufficient to cover it; thus it is boiled, till it be very clear and red on cutting it, when it is again taken out and set to drain. After having undergone this process, it stands to cool, while the jars are getting ready for storing it; at the same time, the liquor in which it was fried is poured upon it, and as soon as it is thoroughly cold the vessels are closely stopped. Preserved in this manner, it will remain hard, and keep two years; indeed, the hardest is considered the best and most palatable. It is brought to table sometimes fried with eggs and garlic, or stewed with a little lemon juice poured on it.

4308. *Jerked beef* is a name given to a method of curing beef in the West Indies and South America. It is there difficult to preserve beef by pickling; but they cut the meat into slices, dip it into sea-water, or brine, and dry it in the sun. In this manner they preserve the flesh of the wild cattle at Buenos Ayres, from whence a great deal is exported to Brazil and Havana for the slaves, and is found to be excellent food. Sometimes, also, they pound this dried meat in a mortar into a uniform paste, which is pressed into jars; and if required for travelling, they beat it up with maize-meal and press it into leather bags; prepared in this way, it is eaten without farther dressing by fire. Captain Owen, in his late "Survey of the East Coast of Africa," mentions American ships bound for India being supplied with jerked beef at Madagascar.

4309. *Some kinds of fish are dried*, when they are below a certain size, merely by slitting them, and by exposure to the air, so as to evaporate their moisture; these will preserve fresh perfectly well if kept from damp. Small cod and haddock are often treated in this manner, and the stock-fish of the north of Europe. In the large kinds of fish, however, the desiccation seldom proceeds with sufficient rapidity, and the addition of salt is found necessary to prevent putrefaction taking place before they can be sufficiently dried in the air.

4310. *By drying meat from air alone*, a great part of the nutritive juices are dissipated, and its flavour considerably impaired, which forms a great objection to this mode of preserving.

4311. *Portable soup* comes into this class of substances preserved as food by drying. The principle upon which it is made is the same with that of manufacturing glue. The gelatin of meat is dissolved by boiling water; and the water being afterward evaporated, the gelatin is left in a solid state. Any fresh lean meat will answer for this purpose, but the fat should be cut away. Portable soup, made in large quantities, forms a valuable acquisition to the traveller, and to those engaged in naval and military duties.

4312. *Dr. Kitchener* endeavoured to ascertain by careful investigation the best and cheapest mode of making this soup. The legs and shins of beef he found to answer better than other meat, both in regard to quantity and flavour. If expense is not a principal object, the addition of other meat, and the trimmings of poultry and game, together with lean ham, in the proportion of one pound to eight of beef, will greatly improve the flavour. Made without ham, the price of this essence in the shops is from 10*s.* to 12*s.* the pound; made in a private kitchen, Dr. K. estimates the expense to be scarcely more than 3*s.* 6*d.* per pound. One ounce of this (2½*d.*) will make a pint of broth; double that quantity with the addition of either thickening or flavouring ingredients, the same quantity of soup.

4313. *To make portable Soup.*—Take a leg or shin of beef weighing about ten pounds; have it from a bullock recently killed; break the bones, and put it into your soup pot; just cover it with water, and set it on the fire to heat gradually till it nearly boils. It should boil for nearly an hour. When scum rises it should be carefully skimmed off, and a little cold water be poured in once or twice, which will cause more scum to rise on the surface, which must be again removed. When the scum has ceased rising, let it boil for eight or nine hours, and then strain it through a hair sieve into a stone jar, and place it where it will quickly cool. The next day, after removing every particle of fat, pour it quite through a very fine sieve, or tamis, into a stew-pan, taking care that none of the settlings at the bottom go into the stew-pan. After adding a quarter of an ounce of black peppercorns, let it boil briskly, the pan uncovered, until it begins to thicken, and is reduced to about a quart. All scum that rises must be removed, as in the preceding process, but without adding water to it. When it begins to thicken, withdraw it from the brisk fire, and place it where it can continue to boil gently until it becomes a very thick sirup. Great care must be taken to prevent it burning, which would in one instant destroy the whole. Pour out a little in a spoon, to ascertain if it will jelly. If it does not, then boil it longer, and at length pour it into a little potting jar, about an inch and a half in depth and perfectly dry. These pots Dr. Kitchener recommends, if the soup is intended for home consumption, and is sufficiently concentrated to keep for six months. If to be longer preserved, it may be put into bladders such as are used for the German sausages; or it may be dried in the form of cakes, by pouring it at first into a dish until cooled. When cold enough to turn out, weigh the cake, and divide it into pieces of an ounce or half an ounce each; place them in a warm room, and turn them twice a day for a week or ten days, by which time they will be thoroughly dried. If kept in a dry place, they may be preserved for years.

4314. Portable soup, besides being very serviceable to travellers, is also very convenient in country places, where it is difficult to have a supply of fresh meat, for making extempore broths, sauces and gravies for hashed or stewed meat, &c. When they are to be used, half an ounce is put into a vessel with half a pint of boiling water, which is to be covered and set upon hot ashes, or put into a water-bath for a quarter of an hour, until the whole is dissolved. If seasoning of roots or herbs is required, they may be added. Boil an onion, with or without a bit of parsley and sweet herbs, and a few corns of allspice, or other spice, in the water you melt the soup in, which may be flavoured with mushroom catsup, essence of sweet herbs, or of celery, or anything else that is customary.

As this portable soup is easily made, and is not only convenient in a family, but economical, since no more need be dissolved than is wanted, it is recommended that it be made at home, as affording the only certainty of the goodness of the materials; it may thus be made for less than half the price of that at which it is sold.

4315. *A preparation is made in France, called "Gelatin brut fin,"* from bones; the ends being cut off and the bones cut down the middle to remove the fat, they are steeped in diluted muriatic acid for about ten days, which dissolves the solid part and leaves the gelatin. The acid being poured off, they are soaked afresh in weak acid for a day and a night, and then steeped in water some hours, renewing it five or six times until all the acid is washed out, and finally they are steeped in a very weak solution of sub-carbonate of soda to neutralize what acid may yet remain. 100 lbs. of bones yield about 25 lbs. of gelatin. The gelatin is then dried and cut in the form of dice, and is used for making soup, for which it keeps better than the cakes of portable soup. This kind of prepared gelatin is made in England, and may be had in the London shops; but we wish our readers to observe that we merely mention the fact, without recommending the substance.

SECT. II.—PRESERVATION OF FOOD BY COLD.

4316. If animal and vegetable substances be exposed to a degree of cold below the freezing point of water, the juices are congealed and converted into ice, and during this state they cannot undergo any change whatever; hence freezing becomes a very simple and effectual mode of preserving food in many cases. The inhabitants of northern countries are thus enabled to lay up a sufficient store of provisions for their winter consumption, and to receive supplies from a great distance. Meat frozen at Archangel is sent to Petersburgh and Moscow; and the markets of these places present the extraordinary appearance of immense numbers of hogs, sheep, fish, &c., built up in stacks, in a complete state of rigidity, and as firm as so many statues or stuffed figures. About the end of October, the Russians pack their meat in tubs, with layers of snow between, and preserve it in this way, using it afterward as occasion requires. Veal frozen in this manner, and sent from a distance, is esteemed the finest they have in Petersburgh; and, when properly thawed, it is said that it cannot be distinguished from that which has been recently killed, being equally juicy. The same practice is followed in Canada, Hudson's Bay, and in all countries where the frost is sufficiently steady. All that is necessary is to hang it out of doors till it be frozen as hard as a board.

4317. *But the most extraordinary proof of the power of extreme cold in preserving animal bodies* is in the account given by Pallas of a species of elephant discovered in a frozen state in a mass of ice that was driven on shore on the coast of Siberia, about thirty-five years ago, and which is supposed to have been preserved in that state as long since as the time of the Mosaic deluge; and yet so fresh was the flesh when the animal fell out of the iceberg, that it was fed upon by the bears of the country. The skeleton and great part of the skin are now to be seen entire in the Museum of Petersburgh. The proofs of the great antiquity of this carcass depend upon geological reasoning, which we cannot here enter into; but whatever difference of opinion there may be with respect to its exact age, all agree that it must have been at least thousands of years old, since the climate of Siberia has long been such that no elephants could live there; nor could the carcass have floated from a warm climate, since it must have undergone decomposition during its passage. We can put no limit, therefore, to the period during which organic substances may be preserved when enclosed in ice.

4318. *In our variable climate, this mode of preserving butcher's meat is not so applicable;* but ice is employed with great advantage in the transportation of fish to London. Salmon is brought by this means to the metropolis from all the northern rivers that flow to the eastern coasts of Britain. The practice is said to have been first recommended by a public-spirited gentleman in Scotland, Mr. Dempster, of Dunichar. Every salmon fishery is now provided with an ice-house, and a stock of ice is laid in during the winter; the salmon are packed in large oblong wooden boxes, with pounded ice interposed between them; and in this manner they are conveyed to the London markets as fresh as when they were taken out of the water, but it is to be observed that they are not actually frozen. Almost all fishmongers have either ice-houses or ice-cellars for the preservation of their fish in tubs of ice. But whenever meat, fish, or vegetables are frozen, it is of the utmost importance to attend to the manner in which heat is subsequently restored; if thawed too rapidly by putting them before the fire, or into hot water, putrefaction is soon induced; and though it may be cooked before that time, yet the flavour is destroyed, and it becomes hard. It is necessary, in order to have the frozen substances unimpaired, to thaw them by immersion in *cold* water. A crust of ice will then be seen gathering round them on the water, owing to their abstraction of heat from that fluid.

4319. But although meat and fish are perfectly preserved by ice, it is doubtful whether the flavour does not suffer in some degree, at least in this country. Some are of opinion that when they have once been frozen, they never completely regain their fine flavour. Taking advantage, however, of the usual cold of our winter, and exposing animal food of any kind to a temperature not quite so low as freezing, so that the juices are not converted into ice, does not produce any injurious effect upon the flavour, but, on the contrary, renders the meat more tender, while all the sapid qualities are perfectly preserved.

4320. *The most complete mode of employing ice in this country for the preservation of food is by a well-contrived ice-house;* but where this cannot be had, many methods more economical may be employed. See "Ice-house," Book VIII., Chap. VII.

SECT. III.—PRESERVING ANIMAL FOOD BY SALT.

4321. *The power which salt possesses of preserving animal food* from decomposition has been known from time immemorial. In the early periods in this country, before markets were so well supplied as they now are with fresh meat, the barons and other wealthy persons laid in an immense store of salted provisions against the winter; for so wretched was the state of husbandry, that they often had not subsistence for their cattle during the winter months, and they killed some of them for this reason, to preserve the flesh in salt. Thus Hume informs us that when the insurgent barons ravaged the estates of the elder Spencer, in the reign of Edward II., he had in his larder the enormous quantity of 600 bacons, 80 carcasses of beef, and 600 muttons; the latter as well as beef being at that time salted. Nor do things appear to have been any better in 1512; for, from the "Northumberland Household Book," we learn that during the winter months the family lived on salted meat. The scurvy was then one of the most common diseases in this island, owing, no doubt, to the great use of this kind of food and the scarcity of vegetables.

In later times, it was usual for families in the country to lay in a stock of salted meat in October and November, which served for their consumption during the winter and spring; but in consequence of the universal establishment of markets, butchers' shops, and travelling butchers, this is less necessary, and fresh meat may at present be had in most places almost every day. Large quantities of meat, chiefly beef and pork, are, however, salted for the use of the navy, and for exportation to the East and West Indies, of which Ireland supplies a large proportion. The property which salt possesses of preserving animal substances from putrefaction is of the greatest importance to the empire in general, and to the remote grazing districts in particular. It enables the latter to dispose of their live stock, and distant navigation is wholly dependant upon it, as long voyages could not be undertaken without the usual stock of salt provisions.

4322. *Animal food is rendered harder and less digestible by being salted* for preservation; and the quantity of salt with which it is thus incorporated is greater than is beneficial to health. Hence it is that those who feed much upon salted provisions are liable to peculiar complaints, as was the case with sailors, who in long voyages were often attacked with scorbutic diseases, before the method of preventing them was so well understood as at present, when great care is taken to have supplies of food preserved fresh, and likewise of lemon juice or citric acid.

Salting is at present the most general process by which meat is preserved in the British Isles; and as, in describing the methods of salting provisions, mention is often made of different kinds of salt and their various qualities, we propose to explain the nature of this substance and the modes of preparing it.

Of the various Kinds of Culinary Salt.

4323. *Common or culinary salt is obtained from two sources.* It is found in great abundance in the waters of the ocean, sea-water containing about three per cent. on an average. This substance is also found in the solid form, composing rocks in various parts of the world; this is called *rock salt*, of which there are mines in Cheshire, from which most of our salt is derived. There are likewise many springs of water issuing from the earth so highly impregnated with salt, that they are called *brine springs;* these are supposed to owe their origin to water passing through rock salt below ground, in consequence of which it dissolves a portion of this mineral substance; on evaporating the water of these springs, or sea-water by boiling, salt is procured. From whichever of these sources salt is obtained, it is never quite pure, being at first contaminated with earthy substances, or with other salts; and it has to be purified or refined before it is fit for all domestic purposes. These salts are sulphate of magnesia, or Epsom salt; sulphate of soda, or Glauber's salt; muriate of lime, and sulphate of lime; they are nearly all separated in the process of refining the salt, by chemical processes not necessary to describe in this place. Common salt is generally a little deliquescent, that is, attracts water and becomes damp, which is owing to its not being entirely freed from the muriates of lime and magnesia. Salt should be preserved for immediate use in a salt-box with a close lid, and be kept in a warm, dry place.

4324. *Common salt*, when perfectly pure, was formerly said to consist of muriatic acid and soda, consequently to be *muriate of soda:* at present, chemists consider it as formed of chlorine and sodium, consequently it is *chloride of sodium;* but it frequently retains its former name. It is white, transparent, without smell, with a taste strictly saline, and free from bitterness. When thrown upon a heated metallic plate, or on the fire, it decrepitates; in a greater heat, or red heat, it melts; and in a white heat it is volatilized in white vapour, but is not altered. Water can only dissolve a certain quantity; when it cannot take up any more, the solution is said to be *saturated;* and this is the strongest brine that can be made. Boiling water dissolves more salt than cold; but when the hot solution is suffered to cool, all the salt falls down in a solid state above what the cold water can hold in solution. Hot brine, therefore, can be made stronger than cold, but will remain so only as long as it is in the hot state. To make brine completely saturated, it is best to boil it, and when the solution is cold, it is certain to be as strong as possible.

4325. *Culinary salt may be divided into two kinds:* 1. Bay salt and Fishery salt; 2. White, or fine-grained salt.

4326. *Bay salt* is obtained from the sea-water by evaporating it in large shallow reservoirs by the heat of the sun only. None is made strictly by this method in Britain, the climate being scarcely warm enough; but large quantities are manufactured on the southern coasts of Europe, as France, Spain, and Portugal, and from thence it is imported into this country. It is very large or coarse-grained, in consequence of the slowness of the evaporation, and more or less impure, being brownish, gray, or reddish, according to the colour of the clay which formed the bottom of the pans in which it was made. The bay salt of different countries differs considerably in purity and colour, according to the mode in which it has been manufactured. The more slowly the water has been evaporated, the larger are the crystals of salt, and the more perfect and pure they are. Bay salt is generally considered to be stronger than white salt; but this opinion is erroneous: its superior operation is rather by dissolving slower on account of the large size of its crystals; and hence it is more useful in salting sea stores. It is cheaper than white salt; and although fitter for the same purposes in curing fish and meat, is much less fit for ordinary purposes from its containing much impurity. Little actual bay salt is now imported, as a coarse salt equally useful is manufactured in this country.

4327. *Cheshire fishery salt* is the coarsest grained of all, and is made by evaporating the brine from dissolving rock salt, or natural brine from the springs, by a temperature of 100° to 110°, by which slow evaporation the crystals become large, and better adapted to the use of the fisheries. It is sometimes called British bay salt.

4328. *White salt* is made either by boiling sea-water in places where fuel is cheap, as at Newcastle; or by partly evaporating sea-water by the heat of the sun, and thus reducing it to a brine, which is afterward boiled to salt, as at Lymington in Hampshire; or by boiling the brine of salt springs, as in Worcestershire and Cheshire; or, lastly, by dissolving and boiling rock salt, as in Cheshire. The different states in which salt is prepared for sale have given it various appellations, as *stored* or *lump salt*, *common salt*, *basket salt*, and *Sunday salt*. In making the stored salt, the brine, whether from the natural brine springs, or from the rock salt, is evaporated in wrought iron pans by a heat of 226°, or 14° above the boiling point, a temperature which brine can sustain, although fresh water cannot; as the liquid boils, a scum is taken off, consisting of carbonate of lime, with which the salt was mixed in the earth; when the brine is sufficiently concentrated, the salt crystallizes, while the other salts, the Epsom salt and the Glauber's salt, do not crystallize so soon, and are poured off in the liquid state; these are called the *bittern*, which are crystallized afterward. The salt now purified is put in baskets and drained, and afterward dried upon a stove; this is often called *basket salt;* it is very fine grained, in consequence of the great heat, and is the best salt used for the table.

4329. *The common salt is made by the same process*, but the evaporation is slower, the temperature being only 160° to 170°, and it is not stoved after draining.

Lymington common salt is made by evaporating salt water by means of the sun and air in shallow ponds, till five parts out of six have disappeared, and quick boiling the remainder to dryness.

In Scotch common salt, the sea-water is boiled very quick, and the crystals, or grains, are small, approaching stoved salt.

Salt upon salt is made from bay salt dissolved in brine and recrystallized.

The following table, by Dr. Henry, gives the components in 1000 parts of foreign and British varieties of salt:

Kind of Salt.		Insoluble Matter.	Muriate of Lime.	Muriate of Magnesia.	Total Earthy Muriates	Sulphate of Lime.	Sulphate of Magnesia.	Total Sulphates.	Total Impurities.	Pure Muriate of Soda.
Bay salt	St. Ube's contain of	9	a trace	3	3	23½	4½	28	40	960
	St. Martin's . . .	12	. .	3½	3½	19	6	25	40½	959½
	Oleron	10	. .	2	2	19½	4¼	23¾	35¾	964¼
British salt from salt water	Scotch common .	4	. .	28 or +	28 or +	15	17½	32½	64½	935½
	Do. Sunday .	1	. .	11½	11½	12	4½	16½	29	971
	Lymington common	2	. .	11 or +	11 or +	15	35	50	63	937
	Do. cut .	1	. .	5	5	1	5	6	12	988

	Stoved	1	0¼	0¼	1	15½	. .	15½	17½	982½

4330. *Common or culinary salt is not only important as a preserver, but as a seasoner of food.* No other condiment is in equal request; and it is considered by medical men to be not only a useful, but a necessary stimulant, and that its valuable properties contribute much to health, when used in moderation. Mankind in all ages appear to have had a relish for salt: "Can that which is unsavoury be eaten without salt? or is there any taste in the white of an egg?"—*Job*, vi., 6. In countries where salt is scarce it fetches a good price, and long journeys across deserts are undertaken to procure it. Although salt is known to be a powerful antiseptic, yet, according to the experiments of Sir John Pringle, it, like sugar, is only so in large quantities; this physician found that a small quantity, so far from preventing, promoted putrefaction; and from this fact he concluded that, as we use salt at table in small quantity only, it helps digestion by softening and dissolving our animal food. Its utility is strikingly exemplified in the avidity with which animals in a wild state, guided by natural instinct, seek for the salt pans of Africa and America, and in the difficulties they will encounter to reach them. The great desire that cattle and sheep have for salt is remarkable, and well known to farmers. Lord Somerville attributed the great health of his merinoes to the salt with which they were supplied; in Spain the merinoes have a ton annually to every 100 sheep.

In the interior countries of Africa, the greatest of all luxuries is salt. A child there, according to Parkes, will suck a piece of rock salt as if it were sugar. The poorer class of the inhabitants are, however, so very rarely indulged with this precious article, that to say a man eats salt with his victuals is the same as saying he is a rich man. The long use of vegetable food creates so painful a longing for salt that no words can sufficiently describe it.

Salt among the ancients was the emblem of friendship and fidelity; also of the inviolability of compacts; hence it was used in all their sacrifices and covenants. At this day the Bedouin Arabs consider it in the same light; they have a great respect for bread and salt, and are accustomed to affirm or deny anything by these substances. Hostile as they generally are towards strangers, yet, if they have eaten salt with any one, it would be accounted the greatest of all crimes to rob him, or even to take the smallest article of his baggage. They never break any engagement made with the ceremony of exchanging bread and salt. If a stranger can contrive to oppose this alliance to their rapacity, he is safe among them even in the middle of the desert; the Arab with whom he has tasted them regards him as one of his own tribe. This feeling extends also to India; no natives will ever fight against those whose salt they have eaten.

Considering the utility of salt to be thus established, it may excite surprise why the long-continued use of salted provisions should give rise, as is well known, to diseases.

But it has been observed by Dr. Paris that the salt, when it has combined with animal fibre, in the case of salt meat, is no longer to be considered as the condiment we have mentioned; and although chemistry cannot explain the cause of the difference, yet it is certain that flesh, when salted, is not so digestible as it was before salting.

4331. *In the process of salting, besides common salt, several other antiseptics are frequently employed* to improve the meat; as saltpetre, sugar, vinegar, and spices.

4332. *Saltpetre*, called also *nitre*, is a salt which consists of nitric acid and potash; hence the chemical term is *nitrate of potash.*

It is a natural production, and is found crystallized on the surface of the soil in certain countries and places, particularly among old walls and spots that have been uninhabited. The surface of the ground is swept off frequently, and the saltpetre contained in it is procured by mixing the whole in water; when the salt dissolves, and the impurities have subsided, the former is obtained by evaporation. What is used in England comes from Bengal in a very impure state; it is purified here; that which is of the best quality is in long transparent crystals. Its taste is sharp, bitterish, and cooling; it is possessed of a greater degree of antiseptic power than common salt. Sir John Pringle found that it exceeded the latter four times; hence it is always an ingredient in making strong brines where the saline taste is to be avoided. When common salt alone is used, it is apt to give a greenish tinge to the meat; and those who are desirous of having the beef of a fine red colour, add a little saltpetre, which has the property of giving this colour; but as this salt has also the effect of hardening the meat, and communicating a harsh taste, to correct these defects, some sugar or molasses is likewise added. Those who are desirous of the red colour without using saltpetre, may give it by a little cochineal, which is perfectly harmless.

4333. *Sal prunella*, mentioned in receipts, is the same salt as saltpetre, only it has been melted over a fire, poured out, and made up into cakes.

4334. *The theory of the preservation of meat by means of alkaline salts* does not appear to have been clearly explained. We know that they attract water, and that the existence of this fluid in meat accelerates its decomposition. When applied to meat, the water in the juices unites with them, and they become dissolved, which facilitates their entrance into the pores of the animal substance. The albumen of the meat being thus deprived of its water, is concentrated, and is less apt to putrefy; hence salted meat may be more readily dried in the air than fresh meat.

It is generally understood that salting greatly impairs the nutritiousness of meat. There can be little doubt that the action of long-continued salt is to corrugate and harden the fibrin, rendering it somewhat less easily digestible; but by *a few days' salting only*, probably its nutritive properties are scarcely, if at all diminished; and although certainly in the process some of the juices of the meat are lost, yet these appear to consist chiefly of water tinged with blood. Meat that has been kept very long in salt becomes strongly and disagreeably saline; and it is difficult by soaking in water to expel the salt, for the meat retains it with great obstinacy, even in boiling. Over-salting appears to have no remedy; for if the meat be kept so long in water as to bring the salt from the middle of the mass, the outside will be totally deprived of it; and cutting it in pieces is well known to injure the quality of the meat.

4335. *Salting meat is performed in two ways*, by dry salting, and pickling.

4336. *Dry salting* is performed by packing the meat in dry salt, and sometimes rubbing the surface of it all over with the salt. Packed in salt, the meat will keep longer, but it is made more salt, and is more altered in its nutritious properties than when it is simply cured by pickling. Dry salting is necessary where beef or pork is intended for exportation and keeping in a hot climate. In general, the pieces of the animal best fitted for being salted are those which contain fewest large blood-vessels, and are most solid. Very little salt penetrates except through the cut surfaces, to which it should therefore be chiefly applied, and all holes, whether natural or artificial, should be particularly attended to. For each twenty-five pounds of meat, about two pounds of coarse-grained salt should be allowed; some employ the following mixture: a pound of black pepper, a quarter of a pound of Cayenne pepper, and a pound of saltpetre, all ground very fine, and mixed well with three quarts of fine salt; this mixture is sufficient for eight hundred weight of beef. The pieces should be first sprinkled with the spices, and then the salt and spice should be well rubbed into every part, moulding and turning the meat very often to open the grain. The meat is then to be put into tubs, with a layer of large-grained salt between each piece; the juices of the meat dissolve the salt, and cause it to form a strong brine. In about a week, or rather sooner, some take out the meat, and re-pack it in smaller vessels with more coarse-grained salt; and some add a little spirit of salt in this re-packing to improve the flavour. Cutting out the bones of meat salted in this manner is advantageous. The meat requires to be kept a month in salt before it is fit to use for sea or winter store.

4337. *If the salting is performed immediately after the animal has been slaughtered*, and is still warm, and before the fluids are coagulated, the salt penetrates rapidly by means of the blood-vessels through the whole substance of the meat; and this is the practice in Ireland in the provision trade. In warm climates, it is important to perform the operation of curing meat very quickly, to prevent putrefaction, and Mr. Jackson, in his "Reflections on the Trade in the Mediterranean," informs us that this operation is admirably performed at Tunis, where the heat is 110° in the shade. There a good-sized bullock, of six or seven hundred weight, is killed and salted in three hours. They use a good deal of pepper.

4338. *The recipe given by Admiral Knowles for salting meat* is as follows: "As soon as the ox is killed, let it be skinned and cut up into pieces fit for use, as quick as possible, and salted while the meat is hot; for which purpose have a sufficient quantity of bay salt and saltpetre pounded together, and made hot in an oven, of each equal parts; with this sprinkle the meat at the rate of about two ounces in the pound; then lay the pieces on shelving boards to drain for twenty-four hours; turn them and repeat the operation, and let them lie for twenty-four hours longer; by this time the salt will be all melted, and will have penetrated the meat, and the pieces may then be drained off. Each piece must then be wiped with clean dry cloths, and a sufficient quantity of common salt, made hot likewise in an oven, and mixed, when taken out, with about one third of brown sugar; the casks being ready, rub each piece well with the mixture, and pack them well down, allowing about half a pound of the salt and sugar to each pound of meat, and it will keep good for several years, and eat well. It is best to proportion the casks or barrels to the quantity consumed at a time, as the seldomer it is exposed to the air the better. The same process does for pork, only a smaller quantity of sugar and more salt will answer; but the preservation of both depends equally on the meat being hot when first salted."

4339. *In directions for salting meat and other provisions, we often find bay salt recom-*

mended as preferable to any other; and it will be useful to consider how far this opinion is well founded.

Dr. Henry has shown, by careful analyses, that the Cheshire salt contains less impurities altogether than the foreign or bay salt, and therefore that the latter cannot be stronger; but the bay salt has not so much of the muriate of lime (now called chloride of calcium) and muriate of magnesia, and therefore it is less disposed to dissolve in the air; and bay salt, from the slow way in which the water is evaporated, is crystallized in larger crystals, or is what is called larger grained. Dr. Holland, who seems to have attended much to this subject, is of opinion, that although the different sorts of salts may differ little in their purity, yet from the different way in which they are made, they possess a difference of form, as well as of compactness, which may fit them for various applications, especially in the preservation of animal flesh and provisions. But in every case, the more pure the salt is, and the more free from any admixture of alkaline or earthy saline matter, the more effectual it will be for the purpose of salting. The small-grained salt is better suited for table, the salting of butter and cheese, because it dissolves more readily and incorporates more easily and intimately with these substances; on the same account, it is the most proper for preserving the different kinds of vegetables. For the like reason, of the smallness of its grain, as well as from its consequent readiness of solution, the same sort of salt is best adapted for making the pickle for meat, and for rubbing on and into its substance; salting by it is sooner performed. But it is not so well calculated for *packing* meat, fish, or provision of any kind, as the bay salt, or the common large-grained fishery salt. This is not from any want of purity or strength, but merely from the smallness of the grain, by which it runs more readily into brine, which, by being forced out from between the layers of flesh or fish, by the pressure of these on each other, the different portions of the animal matter are allowed to come into close contact, without having any salt interposed. Whereas, on the contrary, when salt of a larger and firmer grain is employed, a considerable part of it remains a long time undissolved, separating the different layers or portion of meat; admitting, in some degree, the brine to flow and insinuate itself between them, and admitting also a constant new supply of saturated brine, from the gradual solution of the salt in the fluids exuding from the animal matter to every part of the packed provisions. It does not appear, from all these considerations, that the bay salt, which is a foreign commodity, has any real advantage over the salt made in this country of as large a grain, either by sea-water or from the rock salt, and therefore it is desirable that the prejudice in favour of foreign bay salt should be removed, as injurious to our home manufacture. This fact is well illustrated by the practice of the victualling department of Government at Deptford; there, for several years, the large-grained salt manufactured in this country from natural salt brine springs has been the only salt used for packing provisions, after they have been first cured with common salt, or that which is prepared by a heat of 180°. And though these provisions have been carried to the hottest climates, the strength and purity of the salt employed in preserving them have never been called in question; and the provisions are considered equal in every respect to that packed with the bay salt of St. Ube's or any other place. Indeed, what is now sold in the metropolis as bay salt is almost wholly the large-grained salt of home manufacture from natural brine springs. Such salt, however, though it may be equal in quality, should not be charged at the same price as foreign salt. It is said that strongly rooted prejudices in favour of bay salt exist in Ireland and Scotland; but as salt of equal quality can be made in England, it is very desirable that the large sums paid for bay salt may be saved to the country.

4340. *In domestic economy, salting is sometimes performed only by rubbing in salt;* but this is less efficacious than pickling in brine, or packing in dry salt, and frequently fails when it is wished to keep the meat long; it answers very well where the meat is to be used in a short time.

It is desirable to avoid salting meat in hot weather, if it is to be kept for any length of time; and, in particular, it is improper for the butcher to send meat to any distance in the heat of the day if it is intended for salting; if the meat has been heated, it will not take the salt well. Autumn is the most favourable season for this purpose. If salting in warm weather be necessary, it should be done as soon as possible after the animal is killed; for if it hangs a single day, it runs the risk of being fly-blown, or being tainted in some part, and, if once tainted, it will not take the salt. If the weather be cold, and it cannot be salted immediately on being killed, it will be better for hanging two or three days to become tender, as this change does not take place after it has received the salt; but the first must be guarded against.

For salting, wooden troughs are generally used; some line them with lead, but this is better omitted, as this metal may prove injurious. Glazed salting pans are purposely made of Welsh ware, or Nottingham stone-ware, which answer very well; but common red earthen-ware pans are liable to have the glaze destroyed. The first operation is to clear away any blood or slimy matter that may appear on the meat, and to remove any kernels. It should be then slightly sprinkled with salt, and laid on sloping boards for a day or two for the blood to drain off; and the brine that runs out must be thrown away, as unfit to use again, if the weather be warm, for the blood and other juices that are extracted are apt to putrefy; but if the weather be cold, the brine may be saved to be used over again, if necessary, after boiling. The meat should then be wiped with clean cloths. Dry some common salt in an oven, and bruise it by rolling; some add to this brown sugar, in the proportion of three ounces of salt to one of sugar, which will assist in preserving the meat, and also render it more juicy and mellow. The salt should now be well rubbed into every part of the meat; after which the meat should remain in the trough for a day, and then be turned and rubbed again for several days successively. If it be required to have the meat look read, add half an ounce of saltpetre to the salt; but it is to be observed that this rather tends to harden it. As to the time required for salting, that will depend partly upon the size of the joints, the manner in which the salt has been rubbed in, and the length of time it is required to be preserved. Meat requires, in general, from four or five days to a fortnight, according to the size. Much salt injures its nutritive properties, and makes it tough; but when slightly salted, or *corned*, as it is called, it is still juicy and tender, easily digested, and sufficiently nourishing. Rubbing in salt cannot be applied to fish, on account of their tenderness not bearing the necessary rubbing.

Salt meat is flavoured sometimes by adding to the salt some sweet herbs, onions, &c., pounded, and likewise a little spice.

4341. *Salting meat by pickle* is keeping meat immersed in a pickle, which is a brine composed of common salt dissolved in water. This mode of application does not render the meat so salt as dry rubbing, but is not calculated for keeping it so well for a great length of time, being chiefly limited to small pieces; it is thought, however, to be less injurious to the nutritious quality of the meat.

4342. *A pickle for domestic purposes* is by some recommended to consist of six or seven pounds of salt, and four ounces of saltpetre, to four gallons of water, boiled together, carefully skimmed, and then suffered to get cold before the meat is put in; to this some add a pound or two of sugar, which assists in preserving, without making the meat so salt, and corrects the hardness given by the saltpetre. It is essential that the meat should be kept wholly immersed in the pickle, by laying some weight upon it. Meat preserved in pickle gains in weight. Messrs. Donkins and Gamble found in one experiment a gain of three per cent.; in another two and a half. It should always be kept in mind that the true art of preserving meat by salting is to do with the smallest quantity of salt that can answer the purpose.

4343. *When meat is to be preserved a long time, the brine should consist of a saturated solution of salt.* A common direction in books is, that the brine should be so strong that an egg will float in it; but this is a very imperfect test of its strength, for an egg will not only float in a saturated solution, but in one that has double its measure of common water added to it; and from observing this imperfect direction, and making their brine too weak, some persons have failed in preserving their meat. Indeed, it would be advisable that the brine should not only be as strong as it can be made, but that a little more salt should be added than can be dissolved; because, as the meat is constantly giving out its juices up to a certain period, these juices will lower the strength of the brine below the preserving point; but if there is an excess of salt present, it will dissolve in the juices given out, and thus the strength of the brine will be kept up. A saturated solution of salt is made by dissolving seven ounces and a half of salt in an imperial pint of water at 60°. When the meat has lain sufficiently in the brine, it is to be taken out and packed in casks with dry salt between each layer of meat. *A strong brine or pickle* for preserving meat a long time, or for sea voyages, is made by boiling down the solution; and the rule is, that the water should be evaporated till the salt begins to crystallize, which is known by a thin film of salt beginning to form on the surface when the liquid is on the fire; the water is then completely saturated.

4344. *The same pickle may be used repeatedly*, provided it be boiled up occasionally, with additional salt to preserve its strength, as this is diminished by the combination of part of the salt with the meat, and by the dilution of the pickle by the juice extracted. In consequence of boiling, the albumen, which would cause the pickle to spoil by changing very soon, is coagulated, and rises to the surface in the form of a scum, which must be carefully removed.

4345. Notwithstanding the antiseptic power of the salt, the brine that has been used is very liable to putrefaction; for the blood and all the liquid parts of an animal are more putrescent than the flesh. Mr. Ramsay, of Glasgow, has given an economical process for recovering it: "Dilute the brine with water until its specific gravity is 1·16; then pour it into a clean boiler—cast iron is best; and, to two gallons and a half, add an egg previously beaten up along with two thirds of an ounce of finely-powdered charcoal; boil and skim off the impurities which will then collect. The liquid, on cooling, will be as colourless as water. Any fish or meat to be preserved by this recovered brine must be sprinkled with salt. Different sorts of meat should never be put into the same brine."

4346. *Pickled Pork.*—Pork does not keep long without being salted, not so long as other meat. Great part of what is used for domestic purposes is slightly salted, or, as it is called, *pickled;* this, as is well known, is generally eaten with fresh meat of some kind, as poultry, veal, &c. The method of pickling it is the following: Cut the pork into pieces of a suitable size; rub them well with salt; put them into a pan with a sprinkling of salt between each piece; as the salt melts on the top, strew on more. Lay a coarse cloth over the pan, a board over that, and a weight on the board to keep the pork down in the brine.

4347. *In most farm-houses* where pork is to be kept it is treated thus: When well salted and cut into pieces, it is put into kits; after which it is directed to be covered with brine made sufficiently strong to swim an egg, and simmered over a gentle fire until the impurities which rise are skimmed off; this, when cold, is poured upon the meat, which sometimes remains in that state so long as two or three years before it is used; at which age, it is said, the fat is more firm, of better flavour, and wastes less when boiled than with less keeping.

4348. *All kinds of animal substances may be preserved by salt*, but beef and pork are the only kinds of meat usually cured in Britain as staple articles; and the former is by far the most used in domestic life. Neither of these it is now found necessary to salt to a great degree for home consumption; it is for sea stores chiefly that it is requisite to salt them completely. For distant sea voyages, pork is preferred, for several reasons, which it may be useful to point out. Pork can be preserved by a smaller quantity of salt than beef; it takes up less salt, and is, consequently, less salt to the taste. A piece of pork and a piece of beef were salted as nearly as possible in the same manner; at the end of three months the pork was of a proper degree of saltness, but the beef was so salt as scarcely to be eatable. Every one must have observed that the fat of salted meat is less salt than the lean; and, as pork contains much fat, this may be one cause of the effect mentioned. The fat of fresh pork is too luscious to be relished; but, when salted, it becomes firmer, not so disagreeable to the palate, and is more digestible. Fat, in general, has a less tendency to putrefaction than the lean of meat, as may be observed in oil, tallow, lard, &c.

It is scarcely necessary to observe that too great care cannot be taken that the provisions for the navy should be of the best quality, when we consider the importance of health to sea-faring people, and that they are for a long time deprived of the power of changing their provisions.

Bacon.

4349. *Bacon* is made from the sides and belly of the hog, salted and dried. Each side is called a *flitch* of bacon. This is a very ancient mode of preserving the flesh of the hog; and bacon has long been, and still continues a favourite food among the labouring classes in England, but is scarcely at all used by the same class in Scotland. It is extremely useful in the compositions of the cook. Smoke is generally employed in the drying of bacon, which is effected by hanging it in the wide chimneys of farm-houses. But some persons dislike the flavour communicated by much smoke; and bacon is sometimes cured entirely, or almost entirely without it.

4350. *The general process of curing bacon without smoking* is as follows: It is recommended that the hair should be burned off the hog, after it has been killed, by singing it with kindled straw laid over it, and that the skin should not be scalded, or wetted with water. A large wooden trough, or tray, being provided for the salting, with a gutter round its edges to drain off the brine, the flitches are to be sprinkled over with salt, and left for twenty-four hours in the trough, or on sloping boards, for the blood to drain away thoroughly. They are then to be taken out and wiped dry; the drainings are to be thrown away. Both sides of the flitches, but particularly the inside, or fleshy side, are to be well rubbed with either common salt alone, or, what some prefer, with a mixture in the proportion of three or four pounds of common salt, half a pound of saltpetre, and one pound of coarse sugar or treacle. The salt should be previously well dried in a frying-pan over the fire. When the rubbing is finished, the flitches are placed in the trough upon each other, the skin side lowermost, and next day they should be salted again. They are then to be left in the trough for a month or six weeks, according to the size of the flitches and the state of the weather, rubbing them over with salt four or five times in that time. After this they are dried by hanging them up over the fire, but not in the smoke, and afterward laying them upon a rack hung up to the ceiling in the kitchen, or in some very dry but not too warm a place, nor in the sun, as either of these will cause the bacon to turn rusty. There are some slight variations of this process, as practised in different parts of the kingdom; and it is in Yorkshire and Somersetshire chiefly that bacon is cured without smoking.

A great deal of bacon is cured in Ireland, and imported from thence; but it is not so well fed or cured as the English bacon, and is lower priced.

4351. *Hams are cured* in a similar manner; but this varies in different parts of the country. In Yorkshire they are cured without smoke as follows:

Mix and pound together a peck of common salt, five pounds of bay salt, of saltpetre and sal prunel two ounces each; sprinkle the ham with salt, and lay it down for twenty-four hours; rub it well with the above mixture, and let it remain for three days; then take out the meat, and boil the pickle in two gallons of water, adding salt sufficient to make the brine strong enough to float an egg; when this is cold, pour it over the ham, and suffer it to lie for a fortnight or three weeks; then dry it without smoke, having tied it up in paper to keep away the flies, &c. Some, for the same purpose, whitewash the hams over while they are drying.

See the finishing of bacon and hams by smoking under "Preservation of Meat by Smoking," Sect. V.

Salting Fish.

4352. *In preserving fish, salt is usually more or less employed.* Fish, according to the modes of preserving it, is distinguished into *dry*, *salt*, *green*, and *pickled*. The method by drying alone has been already mentioned; it is used only in the smaller kinds. Pickling fish will be described, Chap. VI.

4353. *Large quantities of cod are salted and dried* in the Newfoundland and Shetland fisheries; these are little esteemed in England, and they are chiefly sent to the Mediterranean, where they fetch a good price, as in the Catholic countries there is a prodigious consumption of fish in Lent. At Newfoundland, the fish, after being gutted and split, are laid in a pile on the shore with a layer of coarse-grained salt, called fishery salt, between each layer of fish; when they have taken the salt sufficiently, they are placed upon stages of wattle-work supported by poles, and exposed to the sun till they are quite dry, when they are packed up and put on board the ships. This mode of preparing the fish is called *curing*.

4354. *Green cod* is the kind most generally used in England. These, instead of being split quite open, like the dry fish, are only opened down to the navel; they are then salted and laid in brine or strong pickle, and put in this manner into casks, without any drying. The finest we have is cured at the Dogger Bank, and is generally brought to the London market two or three weeks after it is caught; the fish sometimes weigh from fifteen to twenty pounds, and are known even to measure from four to five feet in length. But by far the greatest quantity is prepared at Newfoundland; these and the Irish cod-fish are of an inferior quality.

4355. *Haddock, cod, or ling, are cured* by splitting the fish and removing the bone, they are then salted for two or three days with equal parts of salt and sugar, or with salt alone; afterward they are stretched on sticks, and laid on the beach to dry in the sun, or on stages, or within the influence of a kiln or stove.

4356. *Herrings are preserved* by being salted, pickled, or smoked. The Dutch have always been famous for curing herrings, and it has been supposed that they first began the herring fishery; but there is evidence to show that the Scotch had preceded them.

4357. The people of Yarmouth have been long celebrated for salting and barrelling herrings, and for their method of preparing red herrings. They have greatly the advantage over the Dutch in being nearer to the herring shoals.

4358. *To salt herrings*, as soon as they are taken out of the sea they are cut open, and everything is taken out except the milt and the roes; then, after washing them in fresh water, they are left in a tub of strong brine for twelve or fifteen hours. They are drained, and afterward packed up in barrels, disposing them evenly in rows, pressing them well down, and strewing a layer of salt between each row, and another at top and bottom. Mackerel are sometimes cured in the same manner; also pilchards, of which vast numbers are taken off Cornwall, and exported to the Mediterranean.

The same objection that is made to salted meat applies likewise to herrings and other fish; but they are much used by the poor, and are rendered less injurious by a plentiful addition of potatoes; indeed, the best way of using salted herrings is by merely employing them to give a relish to that excellent vegetable.

Sect. IV.—Preserving meat and fish by sugar.

4359. The preservative power of sugar is well known; and though it is not a common practice to preserve meat and fish by it alone, yet this has been done occasionally. Meat has been preserved fresh for months by being immersed in molasses.

4360. To preserve fish by sugar, open them and rub the sugar in, in the same manner as salt, leaving it then for a few days. If the fish be intended for long keeping, dry it after this, taking care to expose new surfaces to the air frequently, to prevent mouldiness. Fish preserved in this manner, it is said, will be found, when dressed, much superior to what has been cured by salt or smoke. For a salmon of six pounds' weight, a table-spoonful of brown sugar is sufficient; and if hardness be required, a tea-spoonful of saltpetre may be added.

Sect. V.—Preservation of meat by smoking, or smoke-drying.

4361. It has been long known that the smoke of burning wood has the property of preserving the flesh of animals from putrefaction. We find from Horace that the making of hams in this manner was practised by the Romans:

"Fumosæ cum pede pernæ."—Sat. ii., 2.

But it is only of late that chemistry has taught us the rationale of the process. A certain portion of salt is almost always employed; but much less is necessary than when no smoke is used, and the smoke imparts a peculiar flavour that is much relished by many persons; the juices of the meat are likewise more perfectly preserved than when it is only salted and dried, by which it is apt to become hard if long kept.

4362. *The usual method of smoking meat in England* is to hang it, after being salted to a certain degree, in those large and wide chimneys which were universally built formerly in our farm-houses, in which they were exposed to the ascending smoke; latterly it has been the custom to erect rooms or houses for the express purpose of hanging meat in to be smoked. The smoke from every kind of fuel is not effectual for this purpose; that from coal does not answer; the smoke of wood and of peat only are fit: nor is every kind of wood equally proper; the quality of the wood has an influence upon the flavour of the meat; beech and oak are preferable to fir or larch. Smoke from the twigs of juniper, rosemary, peppermint, &c., impart to the meat something of their aromatic flavour. Westphalia hams are smoked by juniper; slow smoking is preferable to a more rapid one, as this penetrates more completely into the interior of the meat.

4363. *With respect to the theory of preserving by smoke*, it is now known that in the smoke of wood there is an acid vapour which rises with it, and is the cause of the preservation of the meat. Every one must have remarked how much more pungent for the eyes is the smoke of wood and turf than that of coal; this is owing to the acid just mentioned, which can be procured in a separate state; and as this was at first thought to be one of a peculiar kind, distinct from all other acids, it received the name of *pyroligneous acid*, or acid of wood. But subsequent observations have shown that it is not a peculiar acid, but the same as the acetic, which forms the sour principle *in vinegar*: an opinion which is confirmed by the manufacture of actual vinegar in the distillation of wood. The liquid that comes over first in this distillation is of a dark brownish colour, and consists of acetic acid mixed with tar and water, from which good vinegar is afterward prepared by rectification. The crude liquor still goes by the name of the pyroligneous acid, and is now successfully applied to the preservation of animal substances by simply washing them with it, which is, in fact, making use of the active principle in wood smoke; and this substance might, without much impropriety, be familiarly styled the *essence of smoke*.

4364. *It appears that the first application of pyroligneous acid* to the preservation of meat was made by Mr. Sockett in 1820, from having reflected upon the antiseptic property of wood smoke, and having the opportunity of making some experiments with this acid, made in a manufactory near him. By adding some of it to the pickle for making hams, he found that a much smaller quantity of salt was sufficient; and he even succeeded by brushing over the ham with the acid without employing the pickle. He likewise tried it with success on salmon and herrings.

It should be observed that, after meat or fish have been smoked by the liquid pyroligneous acid, it is necessary to expose it a few days to the air, to take off a peculiar smell.

This opinion respecting the antiseptic property of pyroligneous acid has been completely confirmed by various experiments. Fish simply dipped in it and dried in the shade are perfectly preserved. If haddocks are cleaned, split, and slightly sprinkled with salt for six hours, then drained, and dipped for about three seconds in the acid, and afterward hung in the shade for eight days, they are found to be equal to the highly esteemed *Finnan* haddock. Herrings cured in the same way, and dried in the shade for two months, are equal in quality and flavour to the best red herrings, the fish retaining the shining and fresh appearance which they had when taken out of the sea. A piece of beef was dipped for one minute in pyroligneous acid, in July, 1819; on March 4, 1820, it was as free from taint as when first immersed; no salt was used.

4365. Acetic acid, or pure vinegar, appears to have likewise considerable antiseptic power. Beef and fish dipped in it were found free from taint several months afterward, but when cooked had an insipid taste. The empyreumatic oil, or tar of the pyroligneous acid, is useful in giving that peculiar flavour so much relished in smoked meat. Mr. Donovan observes that pyroligneous acid is, perhaps, more generally made use of in the curing of fish and flesh, as a substitute for wood or turf smoke, than the public are aware of, and that perhaps it acts to the full as well, if not better, for communicating flavour, while it is also an antiseptic. Hams intended for smoke-drying are usually cured with a less quantity of salt than when they are not smoked; even one half the quantity is often sufficient.

4366. Hitherto we have spoken of the pyroligneous acid as possessing the property of preserving meat from putrefaction; and it is sufficient for most practical purposes to take this view of it. But we may now state that late discoveries in chemistry have shown that there *is a peculiar principle in the acid of wood which produces this effect.* A kind of oily substance has been extracted from this acid by Reichenbach, and also from coal tar, to which they have given the name of *creasote.* This oil is transparent, colourless, peculiarly volatile, has a pungent odour, and possesses a very remarkable power of coagulating albumen. That it is this principle in wood smoke and the pyroligneous acid which is effective in preserving flesh is evident from the following facts: If to a solution of albumen in a large quantity of water, a single drop of creasote be added, the albumen is immediately coagulated. When fresh meat is put into a solution of creasote, allowed to remain for half an hour or an hour, then withdrawn, and afterward dried, it may be exposed to the heat of the sun without putrefying, and in the space of eight days it becomes hard, the colour changes to a reddish brown, and the flavour is that of good smoked beef. Fish may be preserved by it in the same manner. M. Reichenbach has ascertained that creasote does not act upon pure fibrin, which by itself is said not to be susceptible of putrefaction. Its action upon living animals is highly deleterious. It is not to be understood from this that pure creasote is to be preferred for this purpose to the pyroligneous acid; it would be much too powerful; and what we have said is merely intended to show that it is really this substance that is the effective agent in wood smoke and pyroligneous acid.

Bacon.

4367. *Bacon is smoked* after it is salted, in many parts of England, particularly in Wiltshire. The treatment is at first nearly the same as has been already described in preparing salted bacon; after which the flitches are hung up in the smoke. Smoked bacon is by some considered as superior to what is salted and dried only; as it is less salt, and thus acquires a flavour relished by some persons. The smoke may be not only from wood, but from straw; but the wood of fir or deal is improper. The best way is to dry the flitches slowly over smoke made by sawdust of oak or beech; the fire may be kept burning in a smothering manner by sawdust, and should be kept up night and day. In some parts of the country, drying and smoking bacon and hams is a separate trade; they charge fourpence or sixpence each for hams, and one shilling for each flitch of bacon; and it saves much trouble to send the flitches to those persons who practice smoking as a business. The flitches should be hung up sufficiently high from the fire, and they should hang till quite dry, but not so long as to get hard and cause the rind to separate. It is not prudent to rub the flitches with bran, as is sometimes done, since this often harbours insects; and great care must be taken to preserve bacon and hams from flies, which lay their eggs there and produce maggots. It is better to put them into coarse calico bags than in paper, as the latter is liable to break and tear.

When large quantities of bacon are to be smoked, it is generally performed in a *smo-*

king-house, prepared on purpose. This is generally a hut about twelve feet square, and the walls seven feet high, with a hole in the roof; joists are laid across in the inside to hang the flitches upon, and the floor is covered five or six inches deep with sawdust, which is kindled, and causes a great deal of smoke, with scarcely any flame.

4368. *What is called rusty bacon* is, in fact, bacon more or less advanced in the process of decay or putrefaction; and though this may be swallowed with impunity in small quantities by strong ploughmen, yet it will prove extremely unwholesome to more delicate stomachs. Bacon, as an article of food for the labouring classes, has many inconveniences, as well as its advantages of convenience and cheapness. It creates thirst, which must be quenched sometimes with beer, and too often leads to ardent spirits.

Hams.

4369. *Hams consist* of a leg or thigh of the hog, salted, seasoned, dried, and sometimes smoked to give it an agreeable flavour. They are cured according to various modes in different places, but it does not appear that the best method has been determined by any well-conducted set of experiments, though the methods are nearly similar to what we have described in the curing of bacon. In those districts which are the most celebrated for the making of good hams, they are first rubbed very hard with salt, and some let them remain for a time upon a stone bench, in order that the brine may drain away; others, on the contrary, cover them up quite close. But whatever method has been followed, after the lapse of a few days they are again rubbed as hard as before, with the same kind of salt, mixed with saltpetre in the proportion of about half an ounce to each ham; and some add sugar. Ude recommends equal parts of sugar and salt. They are then continued about a week longer on the bench, or in the salting tub among the brine, when they are supposed to be ready to hang up to dry. The drying is performed in different modes, according as it is wished to have the hams smoked or not. If they are to be smoked, they are usually hung up in large, wide chimneys where they burn wood or peat, as in Westmoreland, or in smoke-houses. The smoke of peat gives a peculiar flavour. These smoking-houses sometimes consist of two or three stories, the fire being made in the lower one, generally a sunk story, where the previous salting is performed. The meat is hung in the story above, and it is desirable that they shall be at some distance from the fire, that the smoke may arrive at them cool; the principal part of the soot being deposited in the flues of the lower story. From this story the smoke ascends through holes in the ceiling into another placed above, in which sausages and fish are also smoked. It requires about six weeks to smoke meat sufficiently, if it is five or six inches thick; if thinner, less time will do. The smoke penetrates quicker and better in cold weather than in warm; and on this account the process is seldom carried on in the summer season.

4370. Several places on the Continent, Westphalia in particular, are famous for the delicacy and flavour of their smoked hams and other meat; and the manner of smoking them is nearly the same as that just described. In Westphalia, it is said they use juniper wood for the smoking.

4371. In many countries, various kinds of animal food are preserved by smoke-drying besides bacon, pork, and hams. In the north of England, and in Dumfriesshire, mutton and beef hams are smoked. In Germany, venison, geese, and ducks are cured in this manner. The Orkneys were formerly celebrated for smoked geese, and sillocks, a small salt-water fish. The Highlands of Scotland are famous for smoked salmon.

4372. *To prepare hung Beef.*—This is preserved by salting and drying, either without or with smoke. Hang up the beef three or four days, till it becomes tender, but take care it does not begin to spoil; then salt it in the usual way, either by dry salting, or by brine with bay salt, brown sugar, and saltpetre, with a little pepper and allspice; afterward roll it tight in a cloth, and hang it up in a warm, but not in a hot place, for a fortnight, or more, till it is sufficiently hard. If required to have a little of the smoky flavour, it may be hung for some time in a chimney corner, or smoked in any other way: it will keep a long time.

4373. *To make hung Beef in the Dutch Way.*—Take a lean piece of beef; rub it well with treacle or coarse sugar, and let it remain for three days, turning it frequently; after that, wipe it dry, and salt it well with common salt and saltpetre, well dried and beaten fine; turn it every day for a fortnight; roll it quite tight in a coarse cloth, and put it into a cheese press, or under a heavy weight for a day; hang it then to dry in the smoke of wood or turf, but turn it upside down every day.

4374. *The tongues of various animals are preserved by salting and smoking. Neats' tongues* are sometimes pickled only; but they are more commonly salted, dried, and smoked. *Reindeers' tongues* smoked come to us from Norway as a great delicacy.

4375. *Tar vinegar has been used for giving the smoky flavour* to meat. Pour half a pound of the best pickling vinegar over an equal quantity of common tar; stir them together, and let them remain for an hour; then pour off the vinegar. Cut slices from a ham that has been cured with salt, but which is deficient in the smoky flavour, and dip them into this tar vinegar. Broil them, and they will be found to be much improved.

4376. *Curing with smoke is applied very successfully to fish of various kinds. Red herrings* derive their appellation from the brownish red colour given to them by smoke after they have been salted. Yarmouth has been celebrated for many centuries for the preparation of red herrings, and it still stands unrivalled in Great Britain, and is, perhaps, not excelled anywhere. The best kind prepared there are known by the name of "*Yarmouth bloaters.*" The Yarmouth are first salted, and then smoked with wood smoke; but the Dutch use turf, and sometimes straw, for smoking.

4377. *Herrings may be easily smoked* thus: Wipe them clean, and lay them in equal parts of salt and sugar, and a little saltpetre for twenty-four hours; then hang them on a stick by passing it through the eyes. Put some oak sawdust into a cask, and place in the sawdust an iron heated red hot. Fix the stick across the cask, letting the herrings hang within; cover the whole with a cloth, and let it remain for twenty-four hours.

The best way of dressing red herrings, we are told in "Sir John Cochran's Seamen's Guide," is to soak them in water until they become pretty fresh, and hang them up in the sun and wind; then boil or broil them as wanted. In this way they eat extremely tender. Red herrings, though by no means a wholesome food if eaten too frequently, and particularly if the salt be not taken out, yet, from their high flavour, they may be made extremely useful, as a cheap addition to other varieties of food that would be insipid by themselves; and they have the advantage of being easily kept for a very long time.

4378. *Smoked salmon*, called "kippered salmon," is a favourite article of diet in Scotland for breakfast. After taking out the inside of the salmon, scale and split it; then rub it with common salt and Jamaica pepper, and let it drain for twenty-four hours. Mix together salt, coarse sugar, and a little saltpetre, and rub the fish well once or twice with this, and leave it in a tray to pickle for a couple of days; wipe and dry it, stretch it on sticks, and hang it up in the smoke of a turf or wood fire to dry. If less smoking is wished, dry it partly by the heat of a fire or the sun. Kippered salmon is eaten boiled and just warmed through.

4379. *Finnan haddocks* are cured at Findhorn (pronounced Finnan), a fishing village near to Aberdeen famous for this fish, which are considered very delicate, and are much used at breakfast in that part of Scotland; they are split, dried for a day or two in the sun, and hung up for a few days on wooden spits on a wide chimney filled with smoke from a fire made of peat and sea-weed, so as to receive a very slight flavour. These may be had at Billingsgate in London; but great care must be employed in getting them genuine. *An imitation of the Finnan haddock* is commonly made by salting them for a few hours, splitting and wetting the fish with pyroligneous acid, and hanging them to dry.

4380. *Buccaning meat* is a mode of preserving it practised in some parts of the West Indies, and which was employed by the Caribs before their conquest by the Europeans. A number of hunters and pirates, existing in the West Indies about 1630, received the name of "Buccaneers" from their practising this mode of preserving meat.

The flesh was cut into pieces of the length of the arm and salted. Next day the pieces were laid upon a grating, or hurdle, made of sticks, called a buccan, and placed at some height above the ground. A fire of wood was then made below, and a thick smoke produced; the meat was thus partly roasted, partly dried, and also smoked. Large quantities used to be cured in this manner by the hunters, and the meat is said to have a particularly agreeable flavour.

SECT. VI.—PRESERVATION OF ANIMAL FOOD BY VINEGAR.

4381. *The antiseptic property of vinegar* has been long known; but the acid nature of vinegar renders it improper for the preservation of food in general, and it is only employed, combined with salt and spices, in some substances that may be considered among the luxuries rather than the necessaries of life. It is not used for preserving any kind of butchers' meat; and only a few kinds of fish are preserved by it. Its chief employment is in pickling certain fruits, roots, and leaves of vegetables employed as condiments to improve the relish of several kinds of food.

4382. The principle by which acids preserve animal and vegetable substances is the property which they have of coagulating the albumen of the vegetable or animal substance, this principle being peculiarly susceptible of putrefaction.

4383. *Salmon is pickled with vinegar* in the following manner: The fish ought to be perfectly fresh, and in good condition. It must be cut into pieces of convenient size, but the scales are not to be taken off. Make a strong brine, and boil the fish in just so much as will cover it, with some whole pepper and allspice, but take care not to over-boil. When sufficiently done, lay the fish on a slope to drain off the superfluous liquor. When quite cold, pack it up close in kitts, a kind of small, shallow casks, and pour over them some of the brine, together with some good vinegar; let this stand for a day; and then, to make them lie close, strike the sides of the kitt with a mallet, and pack them down as close as possible; then head the kitts. Some boil in the liquor bay leaves, fennel, and tarragon. The kitts should not be opened till wanted for use; the fish will keep after that about a fortnight. The goodness of pickled salmon is known by the brightness of the scales, and their adhering fast to the skin, the firmness of the flesh, and its fine rose colour. If stale, or beginning to spoil, it is extremely unwholesome, and altogether unfit for food.

4384. *To make Caveach, or Pickled Mackerel.*—Take the heads off the fish, open them, and take out the inside, preserving the roes and livers; then divide the fish into quarters. Prepare a seasoning by mixing together a quarter of a pound of salt with two ounces of pepper, half a drachm of mace, a drachm of allspice, and some nutmeg grated; rub well this into the fish, and then fry them of a fine brown with olive oil; drain them dry on a hair sieve, and then put them close into a stone jar, which must be filled up with vinegar; put a little olive oil on the top, and secure the whole with bladder. Mackerel may also be pickled in the same way as salmon.

4385. *To pickle Oysters.*—Put the oysters into a stew-pan, with their liquor, over the fire; do not let them boil, but take them off when they are white and firm; remove the beards; strain the liquor, and put it with twice its quantity of good vinegar into a stone jar; to this may be added some mushroom ketchup, some bay leaves, tarragon, and shallots. Stew the whole in an oven for three hours; when cold, put them into a jar, strewing in with them a little pounded sugar, some pepper-corns, allspice, and bay leaves. Fill up the jar with vinegar, and cork and secure it with bladder.

4386. *Mussels and Cockles* may be pickled in the same manner, and the spices may be varied according to taste.

SECT. VII.—M. APPERT'S METHOD OF PRESERVING FOOD.

4387. *A work was published in Paris in* 1810 *by M. Appert*, entitled "The Art of preserving all Kinds of Animal and Vegetable Substances." The methods employed by the author for this purpose had been in some degree anticipated by Mr. Boyle many years ago, and have, to a certain extent, even been practised by our housewives in this country, at least with respect to vegetables; yet M. Appert does not appear to have been acquainted with any of the former experiments, which had never been followed out and reduced to practical rules: he is therefore entitled to the merit of the invention, which has proved of great utility, and has afforded the most complete mode of preserving meat in the best condition, which has been of late eminently useful in long voyages by sea.

4388. M. Appert received a reward of 12,000 francs from the French government, and he observes, "That before that time two principal methods had been employed for preserving food; that of drying, and that of mingling, in greater or less quantities, some other substance for the purpose of impeding fermentation or putrefaction. By the first of these methods we obtain smoked and hung meat, dried fish, fruits, and vegetables; by the latter, we have fruits and other vegetable substances preserved in sugar, pickles, salted meat, and vegetables. But each of these modes has its peculiar inconveniences. Drying takes away the odour, changes the taste of the juices, and hardens the fibrous or pulpy matter. Sugar, again, from the strength of its own flavour, in a great measure conceals or destroys other flavours, particularly where we wish to preserve the agreeable acidity of certain fruits: it is also very expensive. Salt communicates an unpleasant acerbity to substances, hardens the animal fibre, and renders it difficult of digestion. Vinegar can seldom be made use of, except in certain articles for seasoning."

4389. *To describe the principles of M. Appert's method*, we must observe that animal substances are more liable to decompose, or *spoil* (to use the language of the kitchen), than vegetables, and hence are more difficult to preserve. Many of the latter can be kept quite fresh for a great length of time in their raw state, merely by sealing them in a close vessel, and filling the interstices with some loose substances that will exclude nearly all the air. But meat cannot be preserved raw in the same manner. If raw meat should be treated in this way, its complete change would be much retarded, but it would not be preserved long in a condition fit for food. When meat has been boiled, there is a remarkable difference; the albumen has been coagulated, and, as this is the principle where the putrefaction first commences, cooked meat keeps longer than raw; but it does not by this alone keep any great length of time, except the air be *thoroughly* excluded. Air is essential to the process of putrefaction, and if animal or vegetable substances could be kept wholly out of contact with it, no change could take place. But it is not sufficient that the air is kept from the external part of these substances; that in the interior parts is sufficient to begin the fermentation. Boiling drives out this internal air, and after that, if the substances be placed in a vessel entirely emptied of air, their preservation will be secured. M. Appert's method, accordingly, consists in applying heat to the substances to be preserved so as to coagulate their fermentable juices, and likewise in placing them in such a situation that they shall be deprived of the contact of air. Fabroni and Thenard had previously observed that heat destroyed the fermenting principle in grape juice and fruits, and showed that they might thus be preserved for a long time. It is quite essential that the vessels into which the meat is put should be plunged for some time into boiling water, in order completely to drive out the air; for Gay Lussac ascertained that, though putrefaction cannot take place if air be *thoroughly* excluded, yet the smallest quantity of oxygen gas present is sufficient to produce a commencement of putrefaction, and after the process has commenced, it goes on, whether air be present or not.

4390. M. Appert says, with justice, of his method, "That the great advantage of it consists principally in its application to the service of the navy. It will supply fresh and wholesome provisions for vessels on long voyages, with a saving of more than fifty per cent. Mariners will, in case of illness, be furnished with broth, various and cooling beverages, vegetables, and fruits: in a word, they will be able to partake of a number of alimentary and medicinal substances, which will alone be sufficient to prevent or cure some of the diseases contracted at sea, more especially the worst of them all, the scurvy."

4391. *The preserved substances first presented by M. Appert to the Council of Administration of France* were "Pot-au-feu," a well-known standing French dish of boiled meat, fowls, &c., consommé, milk, whey, green pease, small Windsor beans, cherries, apricots, currant juice, and raspberries. Each of these articles was contained in an earthern vessel hermetically sealed, the cork being fastened with iron wire, and pitched. They had been preserved above eight months. On examination, the pot-au-feu was found to consist of a tolerably rich jelly, with a piece of beef and two pieces of fowl in the middle. When the whole was warmed with care, the soup was found good, and the meat was very tender, and of an agreeable flavour. The consommé was excellent, and quite fresh, though prepared fifteen months. The milk was found to be of a yellowish colour, resembling that of beestings; thicker, as well as sweeter, and more savoury than ordinary milk, a superiority it derived from the concentration it had undergone. Milk prepared in this way was considered nearly equal to the cream sold in Paris; and it did not appear to suffer from uncorking and being put into another bottle. The whey had all the transparency of whey recently prepared, and, though transferred into another bottle, did not begin to lose its transparency till the end of a fortnight. The green pease and beans were as fresh as if just gathered, and the currant and raspberry juice had preserved their aromatic flavour. The reports of French naval officers completely confirmed the expectations which M. Appert had formed respecting the success of this method of preserving provisions.

4392. *Soon after this publication, a patent was taken out in this country* for M. Appert's discovery by Messrs. Donkin and Co., and they succeeded equally in accomplishing the same object. Their method, which is nearly the same as that of M. Appert, is the following:

The meat to be preserved is first parboiled or somewhat more, and freed from the bones. It is then put, together with vegetables, if required, into tin cases or canisters, which are filled quite up with a rich gravy. A tin cover, with a small aperture, is then carefully fixed on by solder; and, while the vessel is perfectly full, it is placed in boiling water, and undergoes the remainder of the cooking. The small hole in the cover is completely closed up while the whole is yet hot. The canister with its ingredients is now allowed to cool, in consequence of which these contract, and the sides of the vessel are slightly forced inward by the pressure of the atmosphere, and become a little concave. The vessel being thus hermetically sealed, and all access of air prevented, it may be sent into any climate without fear of putrefaction, and the most delicate food of one country be thus eaten in its original perfection in a distant region, many months, or even years, after its preparation.

In this manner may all kinds of alimentary substances be preserved: beef, mutton, veal, and poultry; fish and game; soups, broths, and vegetables; creams and custards. Of a quantity taken by Captain Nash to India, not one canister was spoiled, and one which he brought back contained, after two years, beef in the highest state of perfection and preservation, and after having been carried upward of 35,000 miles in the warmest climates. This method has been adopted by the commissioners for victualling the navy, who, having examined some meat so preserved for four years during voyages in the Mediterranean and to America, found it as sound, sweet, and fresh, as if it had been boiled only the day before.

4393. Captain Hall gives his testimony as follows: "I can answer for the perfect preservation of a great number of cases which were in my possession during the voyage to China. I had £88 worth, and not one failure. At that time milk was preserved in bottles corked; but tin cases have been substituted with very great effect. It is really astonishing how excellent the milk is; and, indeed, everything preserved in this way is good. You must, on examining the list of prices, bear in mind that meat thus preserved *eats* nothing, nor drinks; it is not apt to get the rot or to die; does not tumble overboard, nor get its legs broken, or its flesh torn off its bones by knocking about on the decks of a ship in bad weather; it takes no care in the keeping; it is always ready; may be eaten hot or cold; and enables you to toss into the boat, in a minute, as many days' cooked provisions as you choose; it is not exposed to the vicissitudes of markets; nor is it scourged up to a monstrous price (as at St. Helena) because there is no alternative. Besides these advantages, it enables one to indulge in a number of luxuries which no care or expense could procure."

4394. *Considering the great superiority of M. Appert's method* of preserving food to all others before his time, and likewise that there may be many occasions in which it may be practised with great advantage, we shall here give the principal directions which he has published, taken from the original work, in which there are many useful practical hints connected with the details of his process. The use of tin canisters is an improvement by Messrs. Donkin; M. Appert has employed glass and earthen-ware vessels. Messrs. Donkin also have taken care to exclude the air from the interior of the vessels as much as possible, by leaving a small aperture in the lid of the canister, through which the expanded air escapes during the last boiling, rendering the inside nearly a vacuum, a circumstance which does not appear to have occurred to M. Appert. As his methods, however, have rather more simplicity, and though less perfect, yet appear to have answered in general, requiring no tin canisters, which cannot always be so easily procured as bottles and jars, an account of his processes should be generally known.

4395. *M. Appert's Method of preserving boiled Beef, Mutton, or other Meat.*—The meat is first put into a pot to boil in the ordinary way; when three quarters done, half the meat is taken out, and the other half is boiled into a strong broth, which is strained, and part put into a bottle to be preserved. The other half of the meat is put into another bottle, which is struck against a cushion on a table, to shake down the materials, and the bottle is filled up with some of the broth that had been made. Both bottles are then securely corked, and luted in the manner that will be afterward described, and they are placed in a boiler which is filled up with cold water as far as the rims of the bottles or jars. A lid is now put on the boiler, and fire being applied, the water is made to boil, and is kept up at that heat as long as the particular substances require to be thoroughly done, when the fire is put out; in half an hour the water is drawn off by a cock; in another half an hour the lid of the boiler is to be removed; and in one or two hours more, the bottles or jars may be taken out, and placed upon shelves in a cool place.

4396. We shall now describe the methods which he employed to secure his bottles so as to be air-tight previously to their being placed in the boiling water, as mentioned above. As the complete exclusion of the external air from his bottles is essential to the success of the process, his first care is to have the bottles or jars quite sound, and as wide mouthed as the corks would allow. He employed no corks but those of the very first quality, and when he had bottles made on purpose, he had a projecting ring formed on the inside of the neck, more effectually to compress the cork and make it tight. The corking was very carefully performed; the bottles were then enclosed in coarse linen or canvass bags to preserve them from being broken. When he employed jars, he was obliged to join several pieces of cork together to make a stopper large enough; and as his method was ingenious, we shall notice it. He joined together several pieces of cork with isinglass glue made as follows: Having dissolved four drachms of well-beaten isinglass in eight ounces of water over the fire, he filtered the solution through linen, and again put it on the fire to reduce it to one third of the quantity. He then added an ounce of full proof brandy, and left the whole on the fire till it was reduced to three ounces. When he wanted to use this glue, he put some in a little pot over live coals, warmed the pieces of cork, and applied the glue to the surfaces with a brush; he then bound the pieces together with string, and let them dry in the sun or in a gentle heat for a fortnight, when he cut them to the size of his jars. Having corked his jars or bottles, he then covered the corks and edge of the vessel with a lute made of quicklime slacked in the air, and beat up with skimmed milk cheese to the thickness of paste; this hardens very rapidly, and withstands the heat of boiling water. Lastly, he applied strips of linen to this paste, and bound the whole down with two wires crossing each other. If the bottles were to be sent to a distance, he enclosed them in canvass bags, pitched if necessary

4397. In this manner a great variety of dishes are preserved, so as to be sent to distant places, as round of beef, mutton, fowls roasted and fricasseed, young partridges roasted, eels, carp, pike, sweetbread, mushrooms, onions, butter, anchovies. In short, the result of these experiments shows that in this manner all animal productions may be preserved for one, or even two years. But some substances, as broth, jellies, &c., will bear much boiling; other substances will be spoiled by being boiled too long.

4398. *Gravies are preserved* in a manner nearly similar. M. Appert directs that gravy should be made in the proportion of two pounds of good meat and poultry to one quart of water; and the best pieces are to be taken out when one quarter dressed. The gravy is then to be strained and suffered to cool, after which it is to be bottled, corked, luted, and tied as directed above, and placed in the boiler. The boiling should be continued for two hours before the bottles with gravy are properly prepared. The meat and poultry that was taken out may be prepared in other bottles in the manner described above for meat.

4399. *Blood may be preserved* for the use of refiners, or for any other purpose, by putting it into bottles with very narrow mouths without boiling; they must be filled to within an inch of the top, and then have a small quantity of olive oil poured in to the depth of an inch, and then corked thoroughly to exclude the air. Blood has been kept in this manner fresh for two years. M. Appert's method of preserving vegetables will be described in Chap. IV., Sect. III.

4400. *M. Appert's Method of preserving Eggs.*—The eggs are put into a jar with raspings of bread, or bran, to prevent breaking; the jar, corked and luted, is put into a suitable vessel with water heated to 200° Fahr., or 12° under boiling. The vessel with water being taken off the fire, the water is allowed to cool till the finger can be borne in it. The eggs are then taken out, and they will keep fresh for six months.

4401. *M. Appert's Method of preserving Milk.*—Fresh milk was reduced by boiling to one half, and beaten up with the yolks of eggs in the proportion of eight eggs to every ten and a half quarts of milk. The whole is then again placed upon the fire for half an hour, during which time it is to be skimmed frequently; it is then to be strained, bottled, and treated in the water-bath for two hours. This milk kept for two years, and if churned, would afford good butter. *Cream is preserved* by boiling it down from five measures to four; it is then cooled and skimmed, put into bottles, corked, luted, and treated in the water-bath boiling for an hour. This cream will keep two years.

4402. *Many articles of provisions prepared in M. Appert's manner may now be had* in London. These may be carried fresh to the East and West Indies, and are extremely convenient for pleasure yachts, cabin stores, &c. Turtle soup may be had in London preserved in this way, in quarts, three pints, half gallon, and gallon canisters, at the price of 12*s.* 6*d.* per quart, which is found more convenient on some occasions than purchasing the turtle. We subjoin a list with the usual prices, which include the tin cases:

List of Provisions preserved by M. Appert's Method, to be purchased in London.

	s.	d.
Meats.		
Soups and boulli . . per lb.	1	9
Round of beef . . . "	1	9
Roasted beef . . . "	2	0
Boiled beef . . . . "	1	3
A-la-mode beef . . . "	1	6
Mutton, roasted . . "	2	0
" boiled . . . "	1	9
" and green pease "	2	0
Meat in small Cases		
Soup and bouilli for quarts, per doz.	24	0
A-la-mode beef . . . per lb.	24	0
Ragout of mutton . . "	27	0
" " veal . . . "	27	0
Mock turtle . . . . "	27	0
Poultry.		
Ragout of fowls . . per lb.	2	0
" " turkey . . "	2	0
" " goose . . "	2	0
Fish.		
Fresh salmon . . . per lb.	2	3
Stewed eels, per lb. . . .	2	0
Oysters, half pints, per case	1	9
" pints . . "	3	0
Lobsters for fish sauce, quarter pints	1	0
Ditto, half pints	2	0
Vegetables.

4403. *With respect to the mode of finally cooking the various substances so preserved*, there is little to be said: the different dishes of meat and soups, being already cooked, require only to be warmed up; and a variety of jellies and similar preparations that may be preserved in this way will be exceedingly convenient to the cook for sauces and making up dishes. The milk and cream may be used for desserts.

Sect. VIII.—Preservation of Meat by Potting.

4404. *What is termed potted meat consists* of cooked animal substances reduced to a pulp by beating them in a mortar, and having some salt and spices incorporated with them. This pulp is afterward put into jars, and preserved from the air by having a thick coat of melted butter or lard poured over it. Lean meat is best for this purpose. Potted meat is used more as an agreeable and occasional refreshment than as ordinary food.

4405. *The following is the usual method of potting beef*: Take three or four pounds, or any smaller quantity, of lean beef, free from sinews, and rub them well with a mixture made of a handful of salt, one ounce of saltpetre, and one ounce of coarse sugar; let the meat lie in the salt for two days, turning and rubbing it twice a day. Put it into a stone jar, with a little beef gravy, and cover it with a paste to keep it close. Bake it for several hours in a very slow oven till the meat is tender; then pour off the gravy, which should be in very small quantity, or the juice of the meat will be lost; pound the meat, when cold, in a marble mortar till it is reduced to a smooth paste, adding, by degrees, a little fresh butter melted. Season it, as you proceed, with pepper, allspice, nutmeg, pounded mace and cloves, or such of these spices as are thought agreeable. Some flavour with anchovy, ham, shallots, mustard, wine, flavoured vinegar, ragout powder, curry powder, &c., according to taste. When it is thoroughly beaten and mingled together, press it closely into small shallow pots, nearly full, and fill them up with a layer a quarter of an inch thick, of clarified butter, and tie them over with a bladder, or shee India rubber. They should be kept in a cool place.

Any other meat may be potted in a similar way, as ham, veal, game, or poultry of any kind; fish also; char is often potted; also quails; shell-fish, as lobsters, shrimps, prawns, or crabs, may be preserved by the same process. It is essential that fish should be potted perfectly fresh, or as soon as they have been boiled, otherwise they lose their flavour. When made for sale, they have usually too much seasoning; this is done that they may keep till sold; but it overpowers and destroys their flavour.

Some persons prefer, instead of salting the beef as directed above, which as apt to make it hard and less digestible, pounding it when raw with an equal quantity of fat bacon, adding the herbs and spices, together with a few grains of saltpetre. It is then pressed into pots and baked, and, when cold, covered with clarified butter.

4406. *Beef potted to taste like Venison.*—This is made of the flank of beef, the inside skin of which must be pulled off, and the meat slashed across, especially in the thickest parts. It must lie for six hours in pump-water. It must then be salted with saltpetre of the bulk of an egg, mixed with two pounds of common salt. White wine vinegar is to be sprinkled upon it, and it must lie for three or four days, turning it once a day. The brine is then to be washed away with claret. The seasoning must consist of cloves, mace, nutmeg, white and Jamaica pepper; a quarter of an ounce of each, beaten together with savory, thyme, sage, and the rind of a lemon, shredded together, and then well rubbed into the cuts, slashes, and insides. It must be afterward bound with tape, the claret poured over it, the skins laid upon it, and baked in a long pot.

4407. *Potted veal may be prepared* as follows: Take cold fillet of veal; cut off the outside, and pound it with fresh butter, and a little mace and white pepper; then pot it, and cover the surface with clarified butter.

Or, take one pound of undressed lean veal, and put it into a stew-pan with two ounces of butter, the juice of a lemon, and a small quantity of the grated peel, with some mace, salt, pepper, mushroom powder, and some parsley, thyme, savory, and two shallots. Stew these together for ten minutes or a quarter of an hour; have ready a pound of the mellow part of a boiled pickled tongue and half a pound of fresh butter; cut the tongue and veal small, and pound them together; then mix the whole more completely together with the yolks of two eggs well beaten. Press the mass into shallow pots; paper them and bake them in a moderate oven for twenty minutes; when cold, pour over the surface clarified butter.

4408. *Potted Birds.*—Larks, wheatears, or partridges may be potted; and in this state they will keep a considerable time. Take any of these birds that are perfectly fresh, as the least taint will spoil all the materials. When they are emptied, season them inside with allspice powdered, black pepper, and some salt. Press them flat, and stew them for half an hour in a liquor composed of two ounces of fresh butter, a gill of sherry, a table-spoonful of essence of anchovy, with powdered cloves, mace, nutmeg, allspice, and black pepper. After they have been stewed, let them be put in a slow oven to dry; when their moisture is sufficiently exhaled, put them into pots and press them down; fill up the vacuities, and cover them with clarified butter. The liquor in which they have been stewed may be employed for the following preparation.

4409. *Potted Lobster.*—Boil a couple of hen lobsters for a quarter of an hour with plenty of salt; take out the meat from the shell, but do not employ the soft part of the body, and reserve the spawn; stew the meat for half an hour with a large glassful of white wine, a table-spoonful of essence of anchovies, some powdered spices, as cloves, mace, nutmeg, and black pepper. When done, take out the pieces of lobster, which pound with the spawn in a mortar, and let the liquor in which it has been stewed be reduced to a third; to this add a quarter of a pound of fresh butter previously oiled, and mix them well together. Pour this to the pounded lobster, and, when properly incorporated, press it into shallow preserving pots, and cover it with clarified butter. This is an excellent substitute for lobster sauce; in the same manner, you may pot shrimp and cray-fish, or prawns.

4410. *Potted Shrimps.*—When boiled and shelled, season them with salt, pepper, mace, and a small portion of cloves; press them down in a jar, and bake them in a slow oven for ten minutes; when cold, cover them with clarified butter.

4411. *Sausages* are made as a convenient method of preserving many kinds of meat that it would be difficult to keep long in any other mode. The principle of making all sausages is simply chopping fine or pounding the particular kind of meat employed, seasoning it with spices, and herbs of various kinds, bread crumbs and eggs, salt, or mustard, or any of them, mixed in such proportions as are agreeable; then the whole is enclosed in portions of the prepared intestines of a hog, sheep, or calf, very well washed and scraped till thoroughly clean. The herbs employed are some of the following: onions, shallots, sage, thyme, leek, garlic, marjoram, parsley, &c. For some kinds of sausages, besides meat, anchovies, oysters, and red herrings are added. The blood of various animals, as the ox, hog, goose, &c., are used in this way, mixed with oatmeal, crumbs of bread, and seasonings of various kinds. The Germans are famous for their preparation of sausages, in which smoked meat is generally used.

Machinery is now employed for the preparation of sausage-meat on a large scale; but as, in the case of manufactured sausages, the consumer has no method of ascertaining the quality of the ingredients, he should be cautious in their use, as it is well known that meat very improper as food can be used in this way.

4412. *The following preserved meats are to be had in the London shops:*

York, Westmoreland, Westphalia, and Bayonne hams.	Gorgona anchovies and anchovy paste.	Marinate herrings.
Mutton hams.	Hambrough smoked hung beef.	Pâté au Diable, for making grills, &c.
Russia ox and reindeer tongues.	Strasbourg bacon.	Russian caviare.
Neat, smoked, and pickled tongues.	Potted beef.	Bologna sausages.
Welsh dried salmon.	Potted ham.	Modena sausages.
Scotch kippered salmon.	Potted game.	German sausages.
Findhorn haddocks.	Potted shrimps.	Saucissons d'Arles.
Dutch herrings and Yarmouth bloaters.	Potted red herrings.	Saucissons de Lyons.
	Potted char.	

SECT. IX.—PRESERVATION OF BUTTER.

4413. Butter, like the other mild and fat oils, is liable to the change called *rancidity*, which, from the experiments of Parmentier, appears to proceed from the coagulable albuminous or cheesy matter that is mixed with it; and probably the water, which is seldom quite separated from it, assists in the change. Butter not well freed from the milk becomes rancid more readily than that which has been completely deprived of it. By the application of salt, the rancidity of butter is, in a great degree, prevented for some time; but if the butter be melted and deprived of its albuminous part, it may be kept much longer.

The common method of preserving butter is by salting it more or less. Salt, in the proportion of one or two ounces to the pound, according as it is required to be kept for a shorter or longer time, is worked up into the butter till they are thoroughly incorporated.

4414. *Dr. Anderson, in his "Recreations," has recommended another method of curing butter*, by which, he says, with proper care, it may be kept for years in this climate, or carried to the East Indies, if packed so as not to melt.

"Mix two parts of the best salt, one of sugar, and one of saltpetre, and beat them into a fine powder; one ounce of this preparation is sufficient for a pound of butter. This should be thoroughly mixed with the butter as soon as it is separated from the whey, and it should then be put into a clean cask. It should be packed very well down, to exclude the air thoroughly; the top should be covered with a sprinkling of salt, and melted butter poured over it, to fill up every crevice before the cover is fixed down. Butter cured in this manner does not taste well till it has stood at least a fortnight after being salted; but after that time it has a rich, marrowy taste that no other butter ever acquires, and tastes so little salt that one would imagine it would not keep." Dr. Anderson has seen it perfectly sound and sweet, when two years old, in this climate.

4415. *When butter is to be exposed to the heat of a warm climate*, it requires, in order to make it keep, to be clarified before it is salted and packed up. To do this, put it into an iron vessel, and suspend that in another iron vessel, containing water in the manner that chemists make a water-bath, or like a cabinet-maker's glue-pot. Put the whole over the fire till the butter is melted. By continuing the heat some time about 196°, the albumen or cheesy matter will coagulate and settle to the bottom, leaving the butter pure and transparent like oil. When it is nearly cold, take the pure butter off from the dregs that have settled; let it get cold and solid, and salt and pack it up in the same manner as ordinary butter. The use of the double vessel is to prevent the butter from burning, which would give it a disagreeable empyreumatic taste. This purified butter will be somewhat paler than before, and of a firmer consistence; if put into close vessels, and in a cool place, it will keep for some months without salt.

This, according to M. Thenard, is also the method employed by the Tartars to preserve their butter; and he states that if, when used, it be beaten up with one sixth of cheese, it will have much the flavour of *fresh butter*. The bad flavour of rancid butter may, according to this chemist, be removed almost entirely by similar meltings and coolings.

4416. *When a barrel of salt butter is opened*, and consumed slowly, the surface of the butter should be kept covered with strong brine.

4417. *Butter may be preserved without salt*, by incorporating it with honey in the proportion of an ounce to a pound of butter. This has an agreeable taste, will keep for years, and might be useful on long voyages; but as the proportion of honey is considerable, it may not agree with some constitutions.

4418. *The salt butter of Holland* is superior to that of every other country. It forms about three fourths of all the foreign butter we import: *Keil* butter, when it can be had genuine, is excellent.

Irish butter is inferior to that of Britain; chiefly, it is said, owing to want of care in its manufacture.

SECT. X.—PRESERVATION OF EGGS.

4419. However compact and close the shell of an egg may appear, it is nevertheless perforated with a multitude of small pores, too minute to be seen by the unassisted eye. The effect of these, however, is evident, by the daily decrease of the moisture of the egg, through evaporation, and the air taking its place, which operates in effecting its alteration. From the time of its being laid, when the egg is quite full, a fluid is constantly perspiring through the perforations of the shell, which occasions its decay; and this proceeds more rapidly in warm than in cold weather. Although an egg quite fresh is proverbially "full," yet in all stale eggs there is some vacancy, which is in proportion to the loss they have sustained through evaporation. If the end of a fresh egg be applied to the tongue, it feels cold; but that of a stale egg feels warm, because the white of the former being in contact with the shell, abstracts the heat from the tongue more rapidly than the air bubble in the latter.

4420. *To preserve eggs completely fresh*, therefore, this transpiration must be stopped, and the eggs kept full. Any kind of varnish will answer this purpose, but the most convenient substance is mutton suet, or a mixture of that and beef suet. This is rubbed over the eggs; the most effectual method is to dip the eggs into this, melted in a pipkin; olive oil will also answer. They should be afterward wiped, to take off the superfluous fat or oil, which might become rancid, for all that is wanted is to stop up the pores. After this anointing, the eggs should be set on end, with the small end uppermost, wedged close together, one layer over another, in bran, the containing box being closely covered up. Laid upon the side, the yolk will adhere to the shell. They thus come into use, at the end of a considerable time, in a state almost equal to new-laid eggs. They should be done over with the suet as soon as possible after they are laid. Some cover them with a solution of gum Arabic, which is preferable to fat. Eggs are sometimes packed in bran, meal of any kind, wood ashes, salt, or charcoal powder; but these substances are not nearly so effectual alone as when the eggs are first done over with the above mentioned substances, as they can have but a slight influence in preventing the transpiration we have mentioned. Eggs should never be suffered to continue in the nest above a day, since the warmth which they receive in it from the hen is inimical to their keeping. It should be observed, that on the third day after the hen begins to sit on her eggs to hatch them, they are rendered unfit for use.

4421. *From an experiment of Reaumur*, it appears that cutting off the access of air to the embryo in the egg does not kill, or prevent it being hatched, but, on the contrary, preserves it alive for a much longer period than if it had not been treated in this manner. He covered eggs over with spirit varnish, and found them capable of producing chickens after two years, when the varnish was carefully removed.

4422. *It is said that the dealers in eggs* immerse them for a moment in oil of vitriol diluted with water, as a means of preservation. This is not improbable, for the acid would dissolve a little of the calcareous matter of the shell, forming with it a sulphate of lime, which would be deposited and fill up the pores.

Another mode of preserving eggs is to plunge them for five minutes in water heated to 140°; they are then taken out, oiled or rubbed with suet, and packed in sawdust or charcoal powder; they will keep thus for a year or two. Some boil them for one minute, which preserves them a long time, probably by coagulating the portion of the albumen next to the shell. If boiled hard, they will keep many weeks without other preparation.

Eggs are very liable to absorb the flavour of any substance they are kept in contact with, and therefore care should be taken not to pack them in anything that might communicate a flavour; mahogany shavings will impart to them a peculiarly disagreeable taste; and musty straw will likewise give them an unpleasant flavour.

SECT. XI.—PRESERVATION OF MILK.

The changes to which milk is liable have been described in Book VII., Chap. IV. It is well known that it will not remain fresh for many hours in warm weather; the principal care must therefore be to keep it in as cool a place as possible; stone shelves are preferable to wood; and a room connected with an ice-house is particularly convenient The milkmen of Paris, to prevent their milk from turning sour, sometimes use a little subcarbonate of soda, which unites with the acid as it forms; provided too much soda is not employed, this will have no injurious effect; a little calcined magnesia will answer the same purpose.

Milk boiled with sugar will keep some time.

4423. *Cream may be preserved* for several weeks, or even months, in the following manner: Dissolve in water an equal weight of white sugar with cream you wish to preserve, using only so much water as just to melt the sugar and make a rich sirup. Boil this, and while hot, add the cream, stirring them well together. When cold, put this into a bottle and cork it well.

4424. *M. Appert's method*, already described, appears to be a perfect and simple method of preserving milk and cream without sugar, and that even in long voyages.

4425. *A method of preserving milk* for use for any length of time has been invented by M. Dirchoff, a Russian chemist. New milk is slowly evaporated over the fire until it is reduced to a solid substance; this is powdered and put into a bottle, which is accurately sealed with wax. When it is required to use it as milk, some of the powder is put in a proper quantity of water, and it has then all the properties, as well as the taste of milk.

CHAPTER XIII.

PRESERVATION OF FRUIT AND VEGETABLES.

4426. *General Remarks.*—From the nature of vegetable substances, and chiefly from their not passing so rapidly into the putrefactive state as animal bodies, the mode of preserving them is somewhat different, although the general principles are the same. All the means of preservation are put in practice occasionally for fruits and the various parts of vegetables, according to the nature of the species, the climate, the uses to which they are applied, &c. Some are dried, as nuts, raisins, sweet herbs, &c.; others are preserved by means of sugar, such as many fruits whose delicate juices would be lost by drying; some are preserved by means of vinegar, chiefly used as condiments or pickles; a few also by salting, as French beans; and others are preserved in spirits. We shall treat of these various modes separately.

In the summer season, during hot weather, various kinds of vegetables, as pease, kidney beans, cucumbers, &c., can be kept in the ice-cold room attached to the ice-house for several days. Fruits gathered in the morning, which is the most proper time, may be there kept cool, and with all their freshness and flavour, until required for the dessert in the afternoon. It is to be observed that the cold should not be so great as to freeze the vegetables.

SECT. I.—USUAL METHODS OF PRESERVING OUR ORDINARY FRUITS, ROOTS, AND VEGETABLES, WITHOUT SUGAR, FOR WINTER'S STORE.

4427. It had long been a desideratum to preserve fruits by some cheap method, yet such as would keep them fit for the various culinary purposes, as making tarts and other similar dishes. The expense of preserving them with sugar is a serious objection; for, except the sugar is in considerable quantity, the success is very uncertain. Sugar also overpowers and destroys the sub-acid taste so desirable in many fruits: those which are preserved in this manner are chiefly intended for the dessert.

4428. *In gathering fruit for winter store*, great care should be taken not to bruise it, nor to break the skin; the injured parts soon rot and spoil the sound fruit in contact with it. To prevent this, gardeners even have instruments for gathering the most valuable kinds of fruit from the trees, without touching it with the hand. Fruit intended to be stored should never be beat off the trees, or by shaking the branches till it drops, if this can be avoided. They are best gathered on a fine day, when they are most likely to be dry; or if this be done on a wet day, they should be dried in the sun, if possible; the more delicate kinds do not bear to be wiped, as this rubs off their bloom, which, when allowed to dry on some fruits, constitutes a natural varnish, closing up the pores, and preventing the evaporation of the juices.

4429. *The usual mode with apples and pears* has been to lay them first in heaps for a fortnight or more, covered with mats or straw, to *sweat*, as it is called; that is, by a very slight fermentation to discharge some of their juice, after which the skin contracts in a slight degree; but this is now generally disapproved of, and it is thought best to carry them at once to the fruit room, where they are laid upon shelves covered with paper, after wiping gently each fruit. The fruit room should be dry and well aired, but should not admit the sun. The finer and larger kinds should not be allowed to touch each other, but should be kept separate; for this purpose, a number of shallow trays should be provided, supported above each other on racks or stands. There should be the means of warming the room in very cold, frosty weather.

Some kinds of apples and pears are gathered before they are quite ripe, and the ripening is completed after they are gathered; this is termed the *maturation* of the fruit, and it appears to be a curious and interesting natural process. This subject has been well examined by M. Couverchel in a paper inserted in the "Annales de Chimie." He conceived that the acid and mucilaginous matters of fruit nearly ripe are converted into sugar by a process which is perhaps chemical, and which has been called the saccharine fermentation. Had such fruit remained on the tree until it was quite ripe, this fermentation would soon have passed into the putrefactive stage, and then the fruit could not be preserved without extraordinary means, such as extreme cold, sugar, &c.

In general, the apples and pears of autumn should be gathered eight days before they are ripe, and maturated in this way; in fact, there are some fruits that are never fit for eating except they are treated in this manner. The principle of life remains in vegetables very differently from what it does in animals; for a branch cut from a tree does not die immediately, but will grow, on being planted, into a new tree. Flowers that have been cut off when only buds blow on being placed in water; and the head of a carrot cut off a little below the top of the root, if placed in a shallow basin of water, will put out leaves, and become a handsome ornament. Mr. Knight is of opinion that, in the case of the maturation of fruit, it still continues to be in a living state though taken from the tree, and that the saccharine matter is formed in the same manner as it would if growing. Pears kept for maturation may be packed carefully with dry moss, bran, or sand dried in an oven, in baskets lined with stout paper; straw is apt to communicate a mouldy taste. They will keep in this way through the winter.

Choice apples and pears are sometimes wrapped singly in paper, and put into glazed jars with covers. When there is no fruit room, a cold cellar may be used, or they may be kept in baskets packed in dry straw, and kept in a dry, cool room.

4430. *Pineapples may be kept* a considerable time by twisting out their crowns, which, being very ornamental, are generally suffered to remain; but in time they will destroy all the juice of the fruit by living upon it.

4431. *Oranges and lemons* may be preserved a long time wrapped up singly in paper, packed in dry sand or jars, and kept in an equal temperature.

4432. *The free access of the atmosphere being one of the circumstances* essential to the decomposition of animal and vegetable matter, it is obvious that the exclusion of it must prevent this effect from taking place, and that, consequently, if such substances are completely kept from the contact of air, they cannot change, or, at least, in a very considerable degree. At a certain depth below the surface of the earth the temperature does not vary, summer nor winter, and it is never so cold there as to freeze. This fact has been taken advantage of in the preservation of provisions. In many parts of Europe, vegetables, such as potatoes, turnips, carrots, onions, &c., are preserved for one or more years by burying them in deep pits in a clay soil, which they burn hard before using, or even in a dry, sandy soil. Caves form excellent cellars, on account of the equality of their temperature.

4433. *Receipts have been often given* for preserving fruit and vegetables throughout the winter upon this principle, such as apples, pears, cherries, gooseberries, currants, green pease, cranberries, &c.

Some apples that had been preserved in pits in the ground were sent to the Horticultural Society on February 14, 1828, in as fresh a state as if newly gathered from the tree. The apples should be of the hardy or keeping sorts, and not more than four or five bushels should be put into one heap. It is requisite to place dry straw at the bottom and sides of the pit, and also to cover the top with straw, before the earth is put over them.

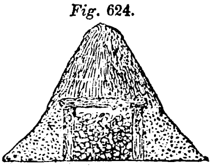
4434. *The undried grapes imported from Spain and Portugal* furnish us with a fine example of a simple mode of preserving fruit. They come in large jars, having sawdust poured in among the fruit to fill up the jars, and the lids are cemented on to prevent access of air.

4435. *To preserve green gooseberries, currants, or green pease* in this manner, let the fruit be gathered in dry weather, or if not, let them be dried in the sun; cut them from the stalks with scissors, and take care that they are not in the least wounded, and that no spoiled or bruised ones are mixed with the rest. Drop them gently into dry, wide-mouthed bottles. Cork the bottles, and rosin over the corks. Make a trench in the garden, at least two or three feet deep, and bury the bottles in it, placing the corks downward, to keep them from the frost. Should the frost in winter be severe, a quantity of litter from the stable should be laid over the place where they have been put. If the bottles are placed in a very cool cellar, the fruit will keep tolerably well. By plunging the bottles, after they are corked, for a few minutes in hot water berries will keep better.

4436. *It is sometimes safer to take up certain vegetables before hard frosts set in*, where the cold is severe, as they may be preserved by artificial means, even by laying on a floor inaccessible to the frost; whereas if left in the ground they would have been frozen and lost. This, in some situations, is the case with cabbages, lettuce, greens, endive, leeks, cauliflowers, &c. They should be carefully removed in dry weather, without injuring the roots too much. Vegetables only a little touched by the frost may be recovered by soaking in cold water.

4437. *Potatoes* are difficult to preserve for many years, and hence they are considered less to be depended upon than wheat against years of scarcity; but as they are seldom required to be kept longer than during the winter and spring seasons, with proper precautions this is not difficult.

Fig. 624.



When preserved in considerable quantities by the farmers, several methods are put in practice in different districts; but the principle appears to be merely to keep them dry, and so protected that the frost cannot reach them. A very effectual method was employed by Mr. Young. He constructed a house capable of holding seven hundred bushels of potatoes, and formed it of fir posts, *a*, *a*, *fig*. 624, having the interstices filled in with watling; against the sides of this he laid straw, and against that, exteriorly, he put earth, rammed tight, six feet thick at the bottom, and eighteen inches at the top. The roof was flat, and he placed on it a stack of beans. The beans kept out the weather, and yet admitted any steam that rose from the potatoes, and which, if it did not escape, would have rotted them. A roof of thatch would have answered. In some parts of the country they are kept during the winter in pits in the ground, where the soil is dry and light, to the depth of three or four feet, lining this with straw, covering them with earth to protect them from the frost, and the whole thatched. Roots, as potatoes, turnips, carrots, &c., should never be divested of the earth adhering to them when taken out of the ground, as it tends to preserve them fresh, the little fibres by which it is retained continuing still to draw some nutriment from it; and if these are broken, the juices escape through the broken surfaces. They should be wounded as little as possible.

4438. *Where the quantity is not considerable*, potatoes may be kept in a cellar underground, where the temperature is pretty equal and never very low, and covered with straw or mats; but in the spring they should be frequently examined and turned over; those which are decayed should be removed, and the shoots broken off closely, if any of them have sprouted.

4439. *Frost appears to have the singular property of converting the starch of potatoes into sugar;* accordingly, when they are affected by frost, or are, as it is called, frost-bitten, they become sweet, and in this state are no longer fit to be eaten, but are generally given to cattle, or are employed for the distillation of spirits, or the making of beer, for which they are even fitter than when fresh. If only slightly injured by the frost, they may be partially restored by thawing them in cold water.

4440. *Carrots and turnips* may be preserved through the winter by taking them up and keeping them in pits, or in a dry cellar in sand, secure from frost. The heads and roots should not be cut off.

4441. *Onions*, when pulled up, should be laid thinly on a gravel walk, and turned every day to dry. When thoroughly dried, they are usually strung together by the tails and hung up in a dry, well-aired place, till wanted for use.

Cabbages are in some places preserved all winter by burying them in the ground, out of the reach of the frost.

4442. *Walnuts, filberts, and chestnuts* are preserved by drying them; then packing them in jars, boxes, or casks, with fine clean sand that has been well dried before the fire, or they may be buried in a pit in the ground, lined with straw.

SECT. II.—PRESERVING FRUIT AND VEGETABLES BY SCALDING, AND BY M. APPERT'S METHODS.

4443. *Scalding fruit* has been employed with success to render their keeping more certain, and is therefore very useful in preparing them for house or sea store.

In 1808, the Society of Arts gave a premium to Thomas Saddington for communicating the following process for preserving fruit without sugar: Fill some stone wide-mouthed bottles with the fruit picked carefully, and set them in a copper or large kettle; then fill the kettle with cold water nearly up to the mouths of the bottles. Corks should be prepared to fit the bottles, and a cloth should be put under the bottoms of the bottles to prevent their breaking with the heat. Light the fire under the kettle, and heat the water to 160° or 170°. This heat should be continued for about half an hour, when the fruit will be sufficiently scalded. After that, fill up the bottles with boiling water to within an inch of the cork, and cork them tight. The bottles should now be laid on their sides, where they are to be kept. During the first month or two it will be necessary to turn the bottles round once or twice a week, and occasionally afterward, to prevent the fermentation that will take place with some fruits from forming into a mouldy crust. Fruit preserved in this manner will keep at sea, even in hot climates. The fruits that may be preserved in this way are apricots, gooseberries, currants, raspberries, cherries, plums, Orleans, egg, or damson, greengages, and also rhubarb cut into small, square pieces. But the most juicy fruits, such as currants, mulberries, strawberries, and raspberries, are not so well calculated for this purpose. In this process the heat seems to act by coagulating and rendering insoluble and inactive a kind of gluten, which is a principal agent in the commencement of fermentation. In the old process, we are sometimes directed not to cork or tie up the vessels till they are quite cool, by which it now appears a very great advantage was lost.

4444. Some fruits may be preserved in a succulent state by being kept in water without boiling. This is practised with regard to the cranberry; it also succeeds with the smaller kinds of apples.

4445. *But the method used by M. Appert,* and which we described as the most perfect mode of preserving animal food, *succeeds equally with vegetables and fruit* of all kinds. There is only this difference, that the vegetables and fruit need not first be parboiled, as in the case of animal food; as they are not dressed, they must be treated in cooking them as raw vegetables.

4446. *The following fruits and their juices* are preserved in this manner: white and red currants, in bunches or stripped; cherries, raspberries, mulberries, &c., apricots, peaches, nectarines, and plums of all kinds; likewise, pears peeled and cut in quarters, with their pips taken out. These fruits are put into strong, wide-mouthed glass bottles, corked with the greatest care, and luted over with a cement made of lime and soft cheese, spread on linen and bound down with wire. The bottles are then enclosed separately in canvass bags and put into a kettle of water, which is gradually heated till it boils; they are thus kept until it is presumed that the fruit is, as it were, boiled in its own juice; the whole is then left to cool, and the bottles are examined to see that they are secure before they are put away for store.

4447. Gay Lussac had found before M. Appert that the *juice of the grape,* or of any other fruit, may be preserved by boiling it for a short time without sugar, and secluding it from contact of air. This prevents fermentation. Grape sirup is much used on the Continent.

4448. *M. Appert's Method of preserving the following Vegetables: Asparagus.*—They are first plunged into boiling water, and then into cold water; to take away their peculiar sharpness. The stalks are placed in the jars with great care, the heads downward; the jars put into the water-bath only till the water boils.

Windsor beans are gathered when small, and put into bottles immediately, as the skins turn brown by keeping; one hour in the water-bath. They may also be stripped of their skins if that is preferred.

French Beans.—The pods put into bottles; if very large, cut in pieces; an hour and a half in the water-bath.

Artichokes.—The stools and very few leaves first plunged into boiling, and then into cold water; after draining, they are half dressed by being placed over the fire in a sauce-pan with butter and seasoning herbs. When cold, they are bottled, and placed in the water-bath half an hour.

Carrots, cabbages, turnips, parsnips, onions, potatoes, celery, cardoons, red beet, and generally all vegetables, may be preserved, either simply scalded or parboiled; put into bottles, and then into the water-bath for an hour.

Green pease may also be kept fresh by M. Appert's method; but they are the most difficult of all the ordinary vegetables to preserve completely. If gathered too young, they dissolve into water; and if they are kept several days before they are bottled, they lose all their flavour, become hard, and ferment, sometimes so as to burst the bottles. They are often very well preserved simply by putting them into well-corked bottles and burying them in a trench in the ground, taking care to invert the bottles. Sometimes they are scalded, drained, dried in cloths, spread on plates, and put into a cool oven, and afterward hung up in paper bags to harden; in which case they must be soaked before they are used. But no method will preserve entirely the sweet flavour and marrowy substance of the young pea. M. Appert's method, however, is the best.

4449. *The following fruits are usually kept in shops preserved in bottles:*

Cherries,	Raspberries,	Greengages,
Moselle cherries,	Gooseberries,	Damsons,
Red currants,	Russian and Swedish cranberries,	Preserved green pease in tins.
Black currants,	American cranberries,	

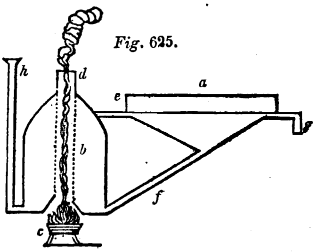
SECT. III.—PRESERVING VEGETABLES BY DRYING COMPLETELY.

4450. Many vegetables, except those which are extremely succulent, may be preserved by drying. For this purpose, they should be well cleaned and spread upon the floor of an oven or kiln, and dried by a gentle and gradual heat, taking care that the heat be not so great as to scorch them. The thicker sorts of roots, as carrots, turnips, potatoes, &c., should be sliced. It is essential that the drying be complete, the interior as well as the exterior parts. After being completely dried, till the leaves crumble between the fingers, they should be packed in paper, or very dry boxes, and put into casks.

Baking apples and pears may be preserved by slicing them about the thickness of a sixth of an inch, and drying them in the sun, or in a slow oven.

4451. *To dry vegetables so as to render them capable of being preserved and ground into flour*, a method was contrived by Mr. Forsyth, which was, to slice the roots and lay them upon a plate of metal heated by steam, which has the advantage of drying them equally without burning. He made the following apparatus for this purpose: *a*, *fig.* 625, is a shallow vessel for holding the sliced roots; *b* is a boiler of water heated by a chafing-dish, *c*, a lamp, or any other mode, the heat from which passes through the boiler in a tube ending at the chimney *d*; *e* is the pipe by which the steam passes from the boiler to the bottom of the vessel *a*; *f* is a waste-pipe for the condensed steam, and *g* a pipe for the waste steam; *h* is a pipe for adding cold water to the boiler. But any other form of boiler will answer; it is only necessary that steam from it shall be conveyed under the bottom of the shallow vessel *a*, into which the vegetables are put; and this may be of any shape and size that may be found convenient.

Fig. 625.

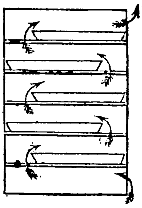


When the starch or flour of potatoes is extracted, it is easily preserved for years by packing it closely in barrels and keeping it dry.

4452. *To preserve sweet and savoury Herbs for seasoning by drying.* Although dried herbs are inferior to those in a fresh state, yet they are still extremely useful. Drying in the sun is often uncertain; and they are better dried in a drying stove, not too warm so as to burn them, or by a good fire. It is important that they should be dried as quickly as possible, that they may not lose their flavour by fermenting and growing mouldy. They should be spread thin, and often turned; and when dry, they should be shaken in a large meshed sieve, to get rid of the eggs of any insects that would otherwise be hatched among them. The same method and precaution should be used in drying flowers; but some succulent flowers, as the petals of the liliaceous plants, cannot well be dried. When dried, rub the leaves off the stalks; pound, sift, and keep them in bottles well corked.

Field's drying closet, *fig.* 626, is convenient for this purpose. It consists of a closet having trays placed in shelves, in which the herbs are put; and a current of air heated by a stove below it is made to enter through apertures, and to circulate between the shelves by an aperture in each, according to the direction of the arrows. The details of construction are described in "Gray's Operative Chemist."

Fig. 626.



4453. *Corn is preserved by drying in granaries.* In some parts of the country, particularly in the east of Scotland, the proprietors of land have had granaries erected on their estates, where, in times of plenty, they store the grain and meal which they receive from their tenants as part of their rent; and it is well known that these storehouses have often been the means of preventing scarcity, and an unreasonable rise in the price of provisions. It is essential to the preservation of grain that it shall be carefully guarded from damp, otherwise it will heat and be damaged. When injured by wet, it may be rendered fit for grinding by being kiln-dried, but it will no longer be fit for sea. Many cargoes have been so heated on long voyages, when shipped in bulk, that the pickaxe was necessary to get it out of the hold, and then it was quite useless, and was burned for manure. The granary of a farm-house in England is generally no more than a room well ventilated and dry, in which the corn is seldom kept above a month or two, usually in sacks. This room is sometimes over the barn, for the convenience of raising the corn into it with ease after it is threshed; occasionally it is a detached building, raised upon stone pillars a little way from the ground; and in this way the corn is deprived of its superfluous moisture, and rendered more fit to be ground into flour. Great care is taken to clear the corn thoroughly from any loose particles that may adhere to it, of dust, chaff, &c., before it is laid up in a granary, in the following method: after bringing it into the granary, it is spread about six inches in thickness, and turned from time to time about twice in a week, and once in a week it is well screened. This management is continued for two months, and after that it is laid a foot thick for two months more, and during this time turned once or twice a week if the season be damp, and now and then screened over. After about five or six months it is raised to five or six feet thickness in the heaps, and then turned over once or twice a month, and screened occasionally. When it has lain two years or more, it is only turned once in two months, and screened once a quarter; but how long soever it is kept, the oftener the turning and screening are repeated, the better the grain will be found to keep. In turning the grain, it is tossed by means of shovels from one part of the room to the other, in which operation the dust and other light substances fall to the floor, while the grain, being heavier, reaches to a greater distance. By these means corn has been kept in granaries thirty years; and it is asserted that the longer it is kept, the more fine flour it yields in proportion to the corn, and the purer and whiter the bread is, the superfluous humidity only having been evaporated in the keeping. At Zurich, in Switzerland, it is said that corn has kept eighty years, or longer, by the same methods of management. It is stated that the public granaries at Dantzic are seven, eight, or nine stories high, having a funnel in the midst of every floor, to let down the corn from one to another. They are built so securely that, though every way surrounded by water, the corn contracts no damp, and the vessels have the convenience of coming up to the walls for their lading. Lord Gardenstone, in his "Travels," informs us that at Geneva, where corn is preserved for a long time in granaries, it is turned about every twenty days for two years, till it acquires a sufficient degree of firmness, and it is then moderately kiln-dried. Insects, particularly the weavil, are very destructive to corn kept in granaries, and they are best kept away by frequent turning and good ventilation, or by keeping the corn completely from access of air.

4454. *In preserving flour*, keeping it perfectly dry is the principal consideration. The barrels, or bins, in which it is contained ought to be of well-seasoned oak, as that is the wood which has the least sap, and is the driest. The soft woods are more apt to imbibe damp, which would cause the flour to turn musty. Fir gives flour the taste of turpentine, and ash is subject to be eaten by worms; oak is free from these faults. Flour is liable to be attacked by small insects, which sometimes do immense mischief where it is laid up in magazines for public uses. These insects have their bodies composed of rings, and are of an oblong, slender form. When they have got into flour, they multiply so rapidly that the only method of saving it from destruction is to convert all that is still left into bread without delay.

4455. *Flour and biscuits carried to sea in the British navy* are preserved in casks made of wrought iron. Formerly these were coated with paint, to prevent oxidation and render them water-tight; but this having been found to communicate a bad taste to the flour, biscuit, or other materials which they contained, they are now coated on the outside with a waterproof composition composed of India rubber (caoutchouc), black resin, and Venice turpentine. For sea store it has been recommended to take out well kiln-dried grain, carefully stored in charred chests, since this will keep better than flour. The grinding could be easily performed by a portable mill.

SECT. IV.—PRESERVING VEGETABLES BY SALT.

4456. Any vegetables may be preserved in a strong brine made by dissolving four pounds of salt in a gallon of water; the vegetables are put into this and kept quite covered with it. French beans, artichokes, olives, samphire, and barberries are often preserved in this manner.

In Holland and Germany, where large quantities of French or kidney beans are salted in every family, a machine is used for cutting them expeditiously, which greatly resembles a turnip slicer. The sliced beans are immediately put into a cask with alternate layers of salt, and a weight being put upon them, they are pressed till they begin to ferment slightly; the salt liquor is then poured off, and they are covered up and put into the cellar as store. Before cooking, they are steeped in fresh water, and are found to be an excellent corrective of the oily qualities of animal food. They are preserved thus for sea store.

SECT. V.—PRESERVING VEGETABLES BY VINEGAR.

We have already mentioned the antiseptic property of vinegar.

4457. *Sauer kraut* is the name of a preparation of cabbage by means of salt and vinegar much used in Germany, and which is likewise found of particular value in long voyages. The mode of preparing it, as described by Parmentier, is the following: The heads of white winter cabbages, after removing the outer leaves, are to be cut into fine shreds, and spread out upon a cloth in the shade. A cask which has had vinegar in it is to be selected, or if none can be had, the inside should be rubbed over with vinegar or sauer kraut liquor. A layer of salt is to be put in the bottom of the cask, caraway seeds are to be mixed with shreds of cabbage, and they are to be packed in the cask to the depth of four or six inches; and layers of this kind, with salt between each layer, are added till the cask is full, stamping them down with a wooden stammer, as they are put in to half their original bulk; some mix a little pepper and salad oil with the salt. Some salt is to be put on the top, and some of the outside leaves of cabbages. About two pounds of salt are necessary for twenty middle-sized cabbages. The head of the barrel is to be placed upon the cabbage leaves, and must be loaded with heavy stones; and a common method is for a man who has clean wooden shoes on to tread the cabbage down in the cask. A fermentation will take place, and some juice will be given out, which is green, muddy, and fetid; this rises to the surface, and is to be replaced by fresh brine. When the fermentation is over, the casks are closed up. Cabbages are preferred, but any other vegetables may be treated in the same manner.

In this country, vegetables are seldom preserved by means of vinegar, except when intended for *pickles*, which are employed only as condiments to add to various dishes.

Pickles.

4458. *There are three modes of pickling in common use. First Method.*—Such vegetables as are hot of themselves, and do not require the addition of spices, and such as do not require to be softened by heat, as capsicums, chili, nasturtiums, button onions, radish pods, horseradish, garlic, and eschalots, are simply put into the strongest vinegar. Some use distilled vinegar, white wine vinegar, or wood vinegar. The jars are half filled with this, and when the vegetables are put in, they are immediately tied down with bladder, leather, or sheet India rubber.

Second Method.—Heating vinegar and spice, and pouring them hot over the vegetables to be pickled, which are previously prepared by sprinkling with salt, or immersing in brine. This method is applied to gherkins, French beans, cabbage, brocoli, cauliflowers, onions, &c. In this method the vinegar is not boiled, as this would diminish its strength by evaporation.

The third method is where the vegetables require softening by heat, as walnuts, artichoke bottoms, beet root, and sometimes onions and cauliflowers.

4459. *In the last two methods, which include the common practice of pickling*, it is necessary that the substance of the vegetables should be penetrated by the vinegar.

As all vegetables abound with their peculiar juices, which, if mixed with the vinegar, would be so diluted as to spoil, it becomes necessary, in the first place, to throw salt on the vegetables, which, to a certain degree, combines with their juices, and is rendered fluid, or they may be boiled in a strong brine of common salt; and this process is in many instances facilitated, as in the case of walnuts, cucumbers, &c., which are covered with a thick skin, by penetrating the vegetables with a needle, so that the action of the salt may be more immediate and penetrating. This loss of the natural juice is afterward supplied by the vinegar they imbibe.

To assist and improve the flavour of the pickle and to correct its sourness, various pungent and aromatic spices are generally added, as pepper, pimento, ginger, capsicums, cloves, mace, or mustard. For the preparation of acid pickles, the vinegar prepared from wood is by some preferred to common malt vinegar, as it contains no mucilage, which renders common vinegar liable to spontaneous decay, and prevents the pickles made with it from keeping well. Another advantage in the wood vinegar is, that it can be had of a greater degree of strength.

Some direct that the pickles should not be boiled in the vinegar, as that would evaporate its strength, and that the best way is to parboil them first in the brine and spices and then taking them out to get cold before they are put into the vinegar, which should be warmed so as to simmer, but not boil. The spices may be simmered with the vinegar. Pickles should be kept carefully from the air, and covers of India rubber can now be had for tying over the jars, instead of bladder or leather; these resist much better the action of the acid.

4460. *The following are examples of the methods usually employed in pickling:*

4461. *To pickle Gherkins or young Cucumbers.*—These should be of the size of the finger; if smaller, they have not attained their flavour; and if much larger, they are probably seedy. Puncture them with a needle, and throw over them some dry salt; when this dissolves, in a day or two, pour it off, and add a fresh quantity, which allow to remain for a couple of days; then take them out, and let them drain on a cloth. Afterward wipe them, put them into jars, and pour on them boiling vinegar in which ginger, black pepper, sliced horse-radish, mace, cloves, and allspice are infused, with shallots or garlic, if agreeable. In two days drain off the vinegar, which boil and pour on the cucumbers. If this process be repeated three or four times they will become perfectly green and plump. French beans may be pickled in the same manner.

4462. *To pickle Onions.*—Take the small buttoned onions, remove the external peel, and throw them into milk and water, in which plenty of salt has been dissolved; set them on the fire, and when they have boiled, pour off the liquor and drain the onions on a sieve. When cold, put them into glasses, and cover them with distilled vinegar prepared in the following manner: Put into a quart bottle some sliced ginger, bruised pepper, and mace; fill it so completely up with distilled vinegar that when it is corked there shall be as little air as possible. When this has stood three or four days to receive the flavour of the spices, render the cork secure by wire, and apply over it a luting composed of lime and white of egg. Put this bottle in a sauce-pan with cold water over the fire, and when it has boiled about ten minutes, remove it in the sauce-pan, and let it there continue till cold. Pour some of this vinegar cold on the onions, and they will keep for many months.

4463. *To pickle Red Cabbage.*—The cabbage should be chosen firm, but the largest are not the best. Trim off the outside leaves, and quarter the cabbages; take out the large stalk and slice the quarters, sprinkle a little salt between the layers; if too much is used, the colour will be injured. Let the whole remain till next day, and shake it, that all the brine may run off; put it into jars with a hot pickle of vinegar, an ounce of black pepper and allspice to each quart of vinegar; also half an ounce of ginger, horseradish, and salt, two capsicums, and a drachm of cayenne. Garlic, eschalots, broccoli, and cauliflowers may be pickled in the same way. The cabbage is at first rather blue or purple; the red colour which it acquires is in consequence of the acid, which has the property of turning all vegetable blues red. This red colour being admired, to heighten it, some add a little cochineal, which is harmless; others add some beet root.

4464. *Pickling Walnuts.*—Take green walnuts, run a needle into each in several places, and throw plenty of salt over them. In three or four days pour off the liquor that has been produced, and add a fresh quantity of salt to extract more of their juice; in about eight days they will become brown and tender. Take them out and let them drain for two days. Arrange them in a jar, and pour over them boiling-hot vinegar containing spices, as ginger, black pepper, cloves, and some garlic, if approved. Leave the jar uncovered as long as any steam arises from them. In two days boil again the vinegar that covers them, and pour it on as before. When cold, secure them from the access of air by a bung covered with bladder, and tied over with leather. Most pickle vinegar, after the vegetables are used, may be turned to use, walnut pickle in particular; it may be boiled up, putting to each quart four or six anchovies chopped small, together with a large table-spoonful of chopped eschalots. Let this stand a few days till it is quite clear, then pour off and bottle. It is excellent for sauce for hashes, fish, and various other dishes.

4465. *Piccalilly, or Indian Pickle.*—White cabbages sliced, cauliflowers pulled to pieces and scalded, radishes topped and tailed, French beans, celery in three inch lengths, shoots of elder peeled, clusters of elder flowers unopened, all salted for two or three days, then mixed with apples and cucumbers sliced, and a large proportion of ginger, turmeric, long pepper, and mustard seed, as the pickle is expected to be very warm; the vinegar must also be the strongest that can be procured, and just sufficient to float the articles; any other vegetables may be used at pleasure.—*Gray.*

4466. *Hot Pickle.*—Pick into moderately sized pieces a cauliflower, puncture some French beans, cut into slices about an inch long some of the red part of a carrot, slice some heads of celery, and pieces of the white part of a cabbage; throw sufficient dry salt over them, which repeat a second time; after which let them dry in the sun for a couple of days; prepare the ordinary spices as before directed, to which add an ounce of genuine cayenne pepper loosely tied up in a muslin rag; let this boil in the vinegar, and afterward let it remain in the jar with the pickles. Boil the vinegar two or three times, and pour it on the pickles; if you wish them of a yellow colour, to resemble the India, add some turmeric to the pickle.

4467. As vinegar is a corrosive substance, capable of dissolving several metals, and likewise some of the glazes of earthen-ware which contain lead, great care must be taken in selecting proper vessels to prepare and keep pickles in, otherwise dangerous consequences may ensue from poisonous matter being introduced into the pickle from the action of the acid upon the vessels containing it. Pickles should never be made or kept in any vessel of metal; for the vinegar will dissolve copper, and produce verdigris, a poisonous substance; and it acts upon lead, forming acetate of lead, another poison; and neither pewter, tin, nor zinc are altogether safe; to say nothing of the inconvenience of having the vessels corroded. Iron is harmless, but is liable to be corroded by vinegar, though slightly. If covered with a glaze containing no lead, it is perfectly safe. It is said that on the Continent they have invented pickling vessels of cast iron, with a lining of thick glass; when the liquid is in the vessel, the glass heats gradually, and does not crack. The safest materials for pickling vessels are *unglazed* earthen-ware, glass, porcelain, or earthen-ware covered with a glaze containing no lead, such as stone-ware. It being thought a desirable quality in many pickles that the vegetables, such as samphire, gherkins, French beans, &c., should preserve their green colour, copper has actually been put in with them expressly for this purpose; but we trust only by those who were unacquainted fully with its poisonous nature.

It is proper to state that directions of this kind are to be found in many books on cooking, as in the "Ladies' Library," vol. ii., p. 203. "Boil the vinegar in a bell metal or copper pot; put it hot on your cucumbers." Now this direction is given, because it was observed that the cucumbers were thus dyed green; but this effect is produced by the vinegar having corroded the metallic vessel, and forming verdigris. Again, in the "Modern Cookery, or English Housewife," we have a receipt for *greening* for pickles, composed of a bit of verdigris, distilled vinegar, and salt; and in Mrs. Raffeld's "English Housekeeper," p. 352, we are told that, to render pickles green, they should be boiled with halfpence, and that the pickle should stand for twenty-four hours in copper or brass pans! When we read directions given with such extreme ignorance of the poisonous quality of copper, it is no wonder that we hear also of many persons being actually poisoned by the use of pickles, to say nothing of health having been injured in numberless instances, without the causes being even suspected.

4468. *In the pickles made for sale*, great importance is attached to their being of a good colour; and there is therefore a strong temptation to use improper means for obtaining this end. As it is impossible to be certain by whom, and how these are made, it appears prudent that every family should, as much as possible, make their own pickles, in order to be thoroughly acquainted with their composition.

The following pickles are usually kept in the shops in London:

Walnuts,	Green capsicums,	Love apples,
Gherkins,	Red ditto,	Piccalilly, after the Indian manner,
Nasturtiums,	Radish pods,	French olives,
Onions, white and brown,	Rock samphire,	Spanish ditto,
Artichokes,	Capers,	Bombay mangoes,
Jerusalem, ditto,	Red Chillies, English,	Melon ditto,
Red cabbage,	Ditto, West Indian,	Garlic,
Cauliflowers,	Horseradish,	Eschalots,
Mushrooms,	English mixed pickles,	Cucumbers,
Beet root,	West Indian ditto,	Capsicums.
French beans,	Ditto, bird pepper,	
Barberries,	Sour-krout,	

Sect. VI.—Preserving by spirits.

4469. Spirits preserve animal and vegetable substances upon the same principle as vinegar; namely, by coagulating the albumen, which is the first to putrefy; but it is seldom or never employed for the preservation of animal food, as it generally renders it hard and indigestible. Fruits are preserved in brandy or other strong spirits. Those which are usually so preserved are plums, apricots, cherries, or peaches. They should be gathered before they are perfectly ripe, and soaked for some hours in very hard water to make them firm. As the moisture of the fruit weakens the spirit, it ought to be strong, and five ounces of sugar should be added to each quart of spirit.

Olive oil is used for preserving a few vegetables, as truffles; the jars should be closely luted to prevent access of air.

Sect. VII.—Preserving fruit and vegetables by means of sugar.

4470. Before sugar was in use, honey was employed to preserve many vegetable productions, though this substance has now given way to the juice of the sugar-cane. Various fruits, flowers, herbs, roots, and juices, when boiled with sugar or sirup, were employed in pharmacy as well as for sweetmeats; these were called *confections*, from the Latin word *conficere*, to make up. Vegetables whose virtues would be lost by drying, or by other modes, may be preserved by means of sugar for a considerable time unimpaired; the sugar preventing the natural decomposition and moulding which would otherwise take place. This method is therefore very effectual, and its expense alone is, in many cases, the chief objection to its use.

4471. In the present day, such is the increase of luxury, that the confectioner forms a distinct profession, which has relieved the domestic establishment, in a great measure, from numerous duties which were formerly considered important and essential. The business of the professed confectioner is very complicated: it requires considerable skill and practice; and in order to exercise his trade, which comprehends the preservation of fruits in a great variety of ways, the preparation of ices and creams, and the making of cakes and ornamental devices, &c., some costly apparatus, and a collection of tools is necessary which a private family would be unable to manage without having devoted a large portion of time to handle them with dexterity and effect. The most difficult preparations of this kind may now be purchased, if not at a cheaper rate than they can generally be made at, at least with a greater saving of time and anxiety: an arrangement which certainly leaves the mistress of a family more leisure to cultivate other branches of knowledge of more importance. Nevertheless, it is extremely useful that all who direct the affairs of a family should have a general knowledge of this as well as other subjects on which many of our comforts depend. But our object in this place is rather to establish some general principles in this part of the preservation of food, illustrated by some examples applicable to the wants of private families, and such as they might easily put in practice, than to enter into all the details of the business of a professed confectioner. Numerous receipts for preserving and for preparing sweet dishes of various kinds which are usually brought to table, or appear at the dessert, will be found in Book XV., Chap. III.

4472. *Confections, or substances preserved by sugar, may be divided into,* 1. *Liquid confects*, or fruits either whole or in pieces, preserved by being immersed in a fluid transparent sirup, as the liquid confects of apricots, green citrons, and many foreign fruits. 2. *Dry confects* are those which, after having been boiled in the sirup, are taken out and put to dry in an oven, as citron and orange peel, &c. 3. *Marmalade, jams,* and *pastes*, a kind of soft compounds made of the pulp of fruits, or other vegetable substances, beat up with sugar or honey, such as oranges, apricots, pears, &c. 4. *Jellies* are the juices of fruits boiled with sugar to a pretty thick consistence, so as, upon cooling, to form a trembling jelly, as currant, gooseberry, apple jelly, &c. 5. *Conserves* are a kind of dry confects made by beating up flowers, fruits, &c., with sugar not dissolved. 6. *Candies* are fruits candied over with sugar after having been boiled in the sirup.

Sect. VIII.—Preserving fruits and vegetables by means of sirup.

4473. Although sugar passes so easily into the state of fermentation, and is, in fact, the only substance, as we have stated, capable of undergoing the vinous stage of that process, yet it will not ferment readily except it be dissolved in a sufficient quantity of water; and it will not ferment at all if the quantity be sufficient to constitute a very strong sirup: hence sirups are used to preserve fruits and other vegetable substances from the changes they would undergo if left to themselves.

A great number of fruits may be preserved in their natural state in a fluid transparent sirup of a proper consistence, that penetrates into every part of the fruit. The method of effecting this requires considerable care; for if the solution of sugar is too weak, in consequence of its tendency to ferment, it will quickly become sour if kept in a temperate degree of heat; such a solution, therefore, is not calculated to prevent the natural fermentation of vegetable juices; and if the sirup be too much concentrated, the sugar crystallizes, and thus spoils the fruit.

4474. *Proper strength of Sirup.*—It has been ascertained that a solution of sugar prepared by dissolving two parts of double-refined sugar in one of water, and boiling this a little, affords a sirup of the right degree of strength, and which neither ferments nor crystallizes. This appears to be the degree called *smooth* by the confectioners, and is proper to be used for the purposes of preserving fruits.

4475. *The sirup employed should sometimes be clarified*, which is done in the following manner: Dissolve two pounds of loaf-sugar in a pint of water; add to this solution the white of an egg, and beat them well. Put the preserving pan upon the fire with the solution; stir it with a wooden spatula, and, when it begins to swell and boil up, throw in some cold water, or a little oil, to damp the boiling; for, as it rises suddenly, if it should boil over, it would take fire, being of a very inflammable nature. Let it boil up again, then take it off, and remove carefully the scum that has risen. Boil the solution again, throw in a little more cold water; remove the scum, and so on for three or four times successively; then strain it. It is considered to be sufficiently boiled when some taken up in a spoon pours out like oil; and when a thin skin appears on blowing upon the sirup, it is judged to be completely saturated. The heat when sufficiently boiled, and of the proper strength, is 221°. In this manner the sirup will become quite transparent. It is scarcely necessary to say that, if a greater quantity of sirup is wanted, the proportions of sugar and water must still be the same. Instead of loaf-sugar, some have used only brown sugar, which they have clarified to do as well as refined sugar, by mixing with the solution some pounded charcoal, which is boiled with the sugar; by straining repeatedly this black mixture, the charcoal is kept back, and the sugar becomes colourless.

4476. *In the confectioner's art* there is a great nicety in proportioning the degree of concentration of the sirup very exactly to each particular case; and they know this by signs, and express it by certain technical terms. But to distinguish these properly requires very great attention and considerable experience.

The principal thing to be acquainted with is the fact, that in proportion as the sirup is longer boiled, its water will become evaporated, and its consistence will be thicker. Great care must be taken, in the management of the fire, that the sirup does not boil over, and that the boiling is not carried to such an extent as to burn the sugar.

4477. *We give the following degrees of boiling the sirup, as distinguished by the professed confectioner;* though, perhaps, such nicety is seldom attained in domestic practice. The 1st degree is called the *thread*, which is subdivided into the little and great thread. If you dip the finger into the sirup and apply it to the thumb, the tenacity of the sirup will, on separating the finger and thumb, afford a thread which shortly breaks; this is the *little thread*. If the thread, from the greater tenacity, and, consequently, greater strength of the sirup, admits of a greater extension of the finger and thumb, it is called the *great thread*. 2d. By longer boiling, you obtain the *pearl*, which is denoted by the thread admitting of being drawn without breaking by the utmost separation of the thumb and finger; this makes candied sugar. 3d. By farther boiling, you obtain the *blow*, which is known by dipping a skimmer with holes into the sirup, and blowing through them; if bubbles are perceived, what is termed the blow is obtained. 4th. The *feather* implies more numerous bubbles; and then the sugar will fly off like flakes while the skimmer is quickly tossed. 5th. The *ball* admits, by additional boiling, the sirup to be rolled into a ball, previously dipping the finger into water, then into the sirup, and subsequently into the water again. 6th. The *crack* denotes that it does not stick to the tooth, and cracks when broken. To know when it has attained this degree, dip a teaspoon or skewer into the sugar, and let it drop to the bottom of a pan of cold water; if the sugar remains hard, it has attained the degree termed *crack*. 7th. The last degree is termed the *caramel*, beyond which a partial burning, or, rather, carbonizing of the sirup will take place. This is a very elegant covering for sweetmeats. We should observe that ornamental confectionery can seldom be executed well but by the hands of professed confectioners.

4478. *Pulpy fruits are preserved whole in sirup*, as follows: The fruits that are the most fit for this mode are, *apricots, peaches, nectarines, apples, greengages, plums of all kinds, and pears.* As an example, take some apricots not too ripe; make a small slit at the stem end, and push out the stone; simmer them in water till they are softened and about half done, and afterward throw them into cold water. When they have cooled, take them out, and drain them. Put the apricots into the preserving pan with sufficient sirup to cover them; let them boil up three or four times, and then skim them; remove them from the fire, pour them into an earthen pan, and let them cool till next day. Boil them up three days successively, skimming each time, and they will then be finished, and in a state fit to be put into pots for use. After each boiling, it is proper to examine into the state of the sirup when cold; if too thin, it will bear additional boiling; if too thick, it may be lowered with more sirup of the usual standard. The reason why the fruit is emptied out of the preserving pan into an earthen pan is, that the acid of the fruit acts upon the copper of which the preserving pans are usually made. From this example, the process of preserving fruits by sirup will be easily comprehended. The first object is to soften the fruit by blanching or boiling it in water, in order that the sirup by which it is preserved may penetrate through its substance. In proportion as the fruit is unripe or hard, it will require to be boiled three or four times in the sirup; when it is of a softer texture, the sirup drained off, and poured on the fruit in its boiling state, will be sufficient, as it is important to retain the shape and appearance of the fruit as perfect as possible.

4479. *Fruits preserved by Sirup without Heat.*—Many fruits when preserved by boiling lose much of their peculiar and delicate flavour, as, for instance, pineapples; and this inconvenience may, in some instances, be remedied by preserving them without heat. Cut the fruit in slices, about one fifth of an inch thick; strew powdered loaf-sugar an eighth of an inch thick in the bottom of a jar, and put the slices on it. Put more sugar on this, and then another layer of the slices, and so on till the jar is full. Place the jar with the fruit up to the neck in boiling water, and keep it there till the sugar is completely dissolved, which may take half an hour, removing the scum as it rises. Lastly, tie a wet bladder over the mouth of the jar, or cork and wax it.

4480. *Dry Confects, or Fruits preserved by boiling in Sirup and drying afterward.*—Any of the fruits that have been preserved in sirup may be converted into dry preserves by first draining them from the sirup, and then drying them in a stove or very moderate oven; adding to them a quantity of powdered loaf-sugar, which will gradually penetrate the fruit, while the fluid parts of the sirup gently evaporate. They should be dried in the stove or oven, on a sieve, and turned every six or eight hours, fresh powdered sugar being sifted over them every time they are turned. Afterward they are to be kept in a dry situation in drawers or boxes. Currants and cherries preserved whole in this manner, in bunches, are extremely elegant, and have a fine flavour. In this way it is also that orange and lemon chips are preserved.

4481. *Marmalades, Jams, and Fruit Pastes.*—The preserves which bear these names are of the same nature, and are now in very general request; they are prepared without difficulty by attending to a few directions; they are little expensive, and they may be kept without spoiling for a considerable time.

4482. *Marmalades and jams differ little from each other;* they are preserves of a half liquid consistence, made by boiling the pulp of fruits, and sometimes part of the rinds, with sugar. The appellation of marmalade is applied to those confitures which are composed of the firmer fruits, as pineapples or the rinds of oranges; whereas jams are made of the more juicy berries, such as strawberries, raspberries, currants, mulberries, &c. *Fruit pastes* are a kind of marmalades, consisting of the pulp of fruits first evaporated to a proper consistence, and afterward boiled with sugar. The mixture is then poured into a mould, or spread out on sheets of tin, and subsequently dried in the oven or stove till it has acquired the state of a paste. From a sheet of this paste, strips may be cut and formed into any shape that may be desired, as knots, rings, &c.

In the more juicy fruits, the pulp is boiled till much of the aqueous part is evaporated before the sugar is added. This is best performed in broad shallow vessels; but, when the pulpy matter begins to get thick, great care is necessary to prevent its burning. This accident is almost unavoidable if the quantity be large, and the fire applied, as is often the case, immediately under the pan; but it may be entirely avoided by putting the pulpy mass, when thickened to the consistence of a sirup, in shallow earthen pans, and placing them in an oven with its door open, moderately heated: in this manner the heat will be applied equally to every part. A still better plan, but more tedious, is to place the vessel containing the pulp in another vessel containing boiling water, which is called the water-bath. The application of steam, by means of what is called the *steam preserving pan*, is the best contrivance for making marmalades, jams, and all other culinary preparations which are liable to become injured by a degree of heat exceeding that of boiling water. See wood-cuts in "Furniture," Book V.

4483. *Orange Marmalade.*—Scoop out the pulp of Seville oranges into a hair sieve, beat it, and press the juice through into a pan below: boil the skins in water in the preserving pan till they are tender; then take out the white part, and cut them into small strips; add this to the juice, and to each pound of the fruit add a pound of clarified sugar, and boil the whole for about half an hour to the degree called the *feather*. Take it off, stir and mix it well, and boil again till it hangs to the spoon, being the degree called the *crack*. Take care not to boil it too much, but watch it carefully, as the proper consistence is important. When right, pour it into pots; cover them with paper dipped in brandy, and tie a bladder over it. Common oranges are not equal to the Seville, but they will make very good marmalade. If the sugar is broken in pieces and boiled with the fruit, without being first clarified, it will do; but then it must be well skimmed as it boils. Marmalade should be made between February and the end of March, as the Seville oranges are then in their best state.

4484. *Scotch orange-chip Marmalade, according to Meg Dods.*—Take equal weight of fine loaf sugar and

Seville oranges; wipe and grate the oranges, but not too much. (The outer grate boiled up with sugar will make an excellent conserve for rice, custard, or batter puddings.) Cut the oranges the cross way, and squeeze out the juice through a small sieve; scrape off the pulp from the inner skins, and pick out the seeds; boil the skins till perfectly tender, changing the water to take off part of the bitter. When cool, scrape the coarse, white, thready part of the skins, and, trussing three or four skins together for despatch, cut them into narrow chips; clarify the sugar, and put the chips, pulp, and juice to it: add, when boiled for ten minutes, the juice and grate of two lemons to every dozen of oranges. Skim and boil for twenty minutes; pot, and cover when cold.

4485. *Quince Marmalade.*—Boil some ripe quinces in a small quantity of water till they are tender; pare the skins off, cut them into quarters, and take out the cores; stew the parings and cores in some water; strain this, and add the water to the quartered quinces. Put the whole into a preserving pan, with as much sugar as the weight of the quinces. Boil this till it is of the proper consistence for a marmalade, bruising it with a wooden spatula.

4486. *A marmalade may be made in the same manner* by using pears, apricots, peaches, pineapples, or any other fruit of a pulpy nature.

4487. *Jams* require the same care and attention in the boiling as marmalade; the slightest degree of burning communicates a disagreeable empyreumatic taste, and if they are not boiled sufficiently they will not keep. That they may keep, it is necessary not to be sparing of sugar.

4488. *Raspberry Jam.*—Pick a sufficient quantity of fresh ripe raspberries, gathered on a dry day; mash them, and pass them through a wicker sieve; to one pint of the pulp add a pound of loaf sugar, pounded or broken small: put the whole into a preserving pan over a clear fire. When it begins to boil, skim it well, and stir it for half an hour, taking great care not to let it burn. When done, put it into small pots, cut some pieces of paper round to the size of the pot; dip them in brandy, and lay them on the jam; also, tie another paper over the pot. Some add a little red currant juice to the raspberries; but this will demand some more sugar: others add a little honey to make it richer.

4489. *Strawberry jam and barberry jam* are made in the same manner. The sugar used may first be clarified: add one sixth of currant juice.

4490. *White Gooseberry Jam.*—This is a homely preparation, but very useful where there are children. It is made as the last, only the gooseberries, which should be quite ripe, must be well boiled until they begin to break. Each pound of fruit requires a pound of sugar; and the gentle boiling must be continued till the jam is of the right consistence. Red gooseberry jam is made in the same way.

4491. *Currant Jam* may be made the same way.

The months when jams and jellies are usually made are June and July. They should be examined in August to see if there be any tendency to fermentation, or any mouldiness; if so, they must be reboiled and prepared over again. In warm seasons this is very liable to happen.

4492. *To preserve Damsons for Pies.*—Take equal weight of fruit and clarified sugar. If any of the damsons are broken, boil them first some time in the sugar; then add the whole quantity of fruit, and boil till it jellies; pot, and tie paper over. But the best mode is Appert's, given already, p. 792.

4493. *Fruit Jellies.*—These are compounds of the juices of fruits combined with sugar, concentrated by boiling to such a consistence that the liquid, upon cooling, assumes the form of a tremulous jelly. Vegetable jelly is a distinct principle existing in fruits, which possesses the property of gelatinizing when boiled and cooled; but it is a principle entirely different from the gelatin of animal bodies, although the name of jelly, common to both, sometimes leads to an erroneous idea on that subject. Animal jelly, or gelatin, is glue; whereas vegetable jelly is rather analogous to gum, though different from it, and not nearly so nutritious as animal jelly or gelatin. (See Book VII., Chap. VII., Sect. IX.) In preparing vegetable jellies, it is necessary to guard against boiling them too long, since this destroys their property of gelatinizing, and they then assume the appearance of mucilage or gum; and this accident is most likely to occur when the quantity of sugar is too small to absorb the water of the juice. Jellies are most perfect as to beauty and transparency when clarified sugar is used; but for ordinary purposes refined sugar answers very well.

4494. *Currant Jelly.*—The usual method of obtaining the juice is to bruise the currants, and to pass them through a sieve; but then it is apt to be turbid and thick. A better mode is to warm the fruit by steaming it, or by putting it closely covered into a slow oven; the juice will then flow from it without much pressure. Put it now in the preserving pan on the fire to boil, in order to evaporate some of the water; let it boil a quarter of an hour; then take it off, skim it, and pass it through a flannel bag to render it clear: add sugar to it in the proportion of a pound and a half of refined sugar to one pint of the juice, and put this on the fire to simmer very gently, until, by dipping a spoon in the jelly, and again raising it, the jelly becomes stiff; then the boiling is sufficient. Take it now off the fire, and let it stand till the scum has collected on the surface; remove this, run the whole through a hair sieve, and put the clear jelly into pots. When cold, cover the surface with jelly paper steeped in brandy. What remains on the sieve will do to make pies, or mix with any common jam; and the jelly will be more delicate if no squeezing is employed. A small proportion of raspberries will improve the flavour.

4495. *White currant jelly* is made in a similar manner; only the finest sugar should be used, and the boiling and straining should be done very carefully, as the colour is easily injured. White raspberry juice may be added. The sugar should be high-boiled.

4496. *Black currant jelly* is generally used medicinally; it is made in the same manner.

4497. *Grape Jelly.*—Spread some of the ripest grapes on straw; at the end of a fortnight pluck them from the stalks, and boil them for five or six minutes only, in order that the juice may be extracted with ease by pressure; next pass the juice through a sieve, add a quarter of a pound of white sugar to each pound of juice, and boil the whole for half an hour, and afterward set it to cool; in twenty-four hours it will be a fine jelly, useful to invalids.

4498. *Robs are vegetable juices simply inspissated* by evaporating most of the water in a vessel over a fire till they acquire the consistence of sirup, which will prevent their running into fermentation. The fruits are to be squeezed in bags to obtain the juices. Sometimes a little sugar is added to make them keep better. Rob of elderberries will keep without sugar, and is sometimes employed medicinally.

4499. *Sirup of Lemons.*—Dissolve by a gentle heat a pound and three quarters of sugar in a pint of lemon juice, and skim it well; add an ounce of lemon peel cut thin; simmer the whole gently for a few minutes, and then strain it; when cold, bottle it, and keep it in a cool place. If lemons cannot be had, this may be made by dissolving crystallized lemon juice in sirup, and flavouring it with sirup of lemon peel.

4500. *Sirup of Oranges* may be made in the same way. Both these are useful for sauces and for punch.

4501. *Sirup of Lemon or Orange Peel.*—Macerate all night in a close vessel, with a pint and a half of boiling water, three ounces of the outer rind of lemon peel or Seville orange; strain and let it stand to settle; pour off the clear part, and add to it two pounds of loaf-sugar; evaporate by a gentle heat till it comes to a proper consistence for a sirup.

4502. *Fruits preserved by Candying.*—All fruits before being candied must first be boiled in sirup, after which they are taken out and dried on a stove, or before the fire; the sirup is then to be concentrated or boiled to a candy height, and the fruit dipped in it, and again laid in the stove to dry and candy: they are then to be put into boxes and kept dry.

4503. *For beautiful preserves for the dessert*, see "Confectionery," Book XV.

4504. *Conserves consist* of fresh vegetable matters beat into a uniform mass with refined sugar; and they are intended to preserve the virtues and properties of recent flowers, leaves, roots, peels, or fruits unaltered, and as near as possible to what they were when fresh gathered, and to give them an agreeable taste. Vegetables whose virtues are soon destroyed by drying, may be preserved in this manner for a considerable time unimpaired. The preparation of conserves is extremely simple. The sugar is first ground to fine powder, and then mixed by long beating (not by solution) with the vegetable pulp, or other material. No heat or other mode of preparation is employed; so that the vegetable matter remains as nearly as possible in the state in which it existed in the plant at the moment of gathering. The most usual of these are conserve of roses, mallows, rosemary; of hips, orange flowers, violets, jessamine, citrons, and sloes: they are chiefly medicinal. The apothecaries, under the title of conserves, comprehend all kinds of confects, both dry and liquid, whether of flowers, fruits, seeds, roots, or leaves, if they are prepared with sugar or honey to preserve them.

4505. *The following fruits and vegetables preserved, chiefly for the dessert, may be had in the shops in London:*

Muscatel raisins in bunches.
Jordan almonds.
Gusinarven, or Portugal plums.
Prunes impériales, the largest sort of French plums.
Prunes de Tours.
Prunes du Roi.
Prunes de la Reine, or prunes fleurées.
Prunes de Brignolles, or prunellas.
Prunes de Mirabelle, or pistolle.
French dried pears.
French dried apples: these keep a long time.
Portugal dried cherries.
Portugal dried peaches.
Elemi, or chosen Smyrna figs.
Turkey flat figs.
Do., in cakes with almonds.
Commadra in cakes, with almonds.
Marseilles almonds.
Almond figs, fig cakes, and almond pines.
Egyptian, Mogadore, and Barbary dates.
Portugal black grapes.
Spanish green grapes.
Hamburgh black grapes.
Malaga and Oporto pomegranates.
Spanish muskmelons.
French and Spanish olives.
Candied orange and lemon peel chips.
Preserved West India ginger.
Preserved East India ginger.
Preserved green limes.
Preserved pineapples.
Preserved tamarinds.
Pineapple jam.
Guava jelly.
Brazil nuts.
Cashew nuts.
American ground nuts.
Pistachio nuts.
Spanish chestnuts.
Fresh cocoanuts with milk.
East India candied ginger.
East India chou-chou.
Preserved nutmegs from Batavia.
Preserved cashew apple.
Apricots, greengages, strawberries, cherries, &c., preserved in apple jelly from Rouen.
The following fruits dried in sirup or in crystal sugar, from Auvergne; apricots, gages, peaches, cherries, strawberries, nectarines, Mogul plums, pineapples, Siberian apples, pears, &c.
Chinois glacés.
Mirabelles de Metz.
Apricot, greengage, and pippin tartlets.
Preserved oranges and lemons, carved, in jelly.
Norfolk biffins and biffin paste.
Gelées de fruit, dried in cakes.
Bottled fruits for tarts: apricots, greengages, peaches, cherries, raspberries, strawberries, currants, damsons, gooseberries, bullaces, rhubarb, American, Russian, and Swedish cranberries.

Marmalades, Jams, and Jellies

Apricot marmalade.
Orange marmalade, Dundee.
Greengage marmalade.
Quince marmalade.
Raspberry jam.
Strawberry jam.
Gooseberry jam.
Barberry jam.
Red currant jam.
Black currant jam.
Pineapple jam.
Red currant jelly.
Black currant jelly
Apple jelly.
Ditto, from Rouen.

If these are put into *patent stone jars*, they will keep very long.

BOOK XI.

ON THE GENERAL ARRANGEMENT OF A KITCHEN, AND ON THE CULINARY PROCESSES, AND APPARATUS FOR COOKING.

CHAPTER I.

INTRODUCTION AND GENERAL REMARKS.

4506. *The situation of the kitchen* with respect to the rest of the house demands the particular consideration of the architect. In London, and in many other large cities and towns, the great value of ground renders it desirable to economize space as much as possible; and hence the kitchen is almost always placed in the basement story. In the country, however, this mode of arrangement is not so necessary, and the kitchen is often a separate, though attached building, which is better on several accounts, as will be perceived from the following enumeration of the requisites of a good kitchen.

4507. 1. It should be sufficiently large, and the parts conveniently distributed. 2. It should be lofty and well ventilated. 3. There should be good light, especially in those places where the cooking is immediately going on. 4. It should be well supplied with water and fuel. 5. There should be easy access to it, without passing through the house. 6. It should be so placed that the odour of the cooking should not be perceived in the house; nor should the latter be incommoded by the noise of the culinary operations and servants. 7. The appendages to the kitchen, as scullery, pantry, store-room, fuel-room, &c., should be arranged near to it. 8. If possible, some of the offices are best placed round a small courtyard, which would be very useful for many operations that are proper to be performed out of doors and out of sight.

4508. It may be sufficient at present to enumerate a few things in the interior that must be attended to in designing every large kitchen. There should be some good side lights as well as a skylight, if the latter be practicable. There must be a sufficiently large chimney, with a kitchen range, stewing stoves in brick, hot plate, roasters, ovens, and other fixtures for cooking, with proper flues, independent of that belonging to the range; dressers, plate-shelves, and other necessary furniture. The floor should be stone, and the skirtings stone or slate. The cooking is carried on by fires made with wood, coal, peat, or charcoal: steam, gas, and lamps are likewise employed; and also combinations of several of these modes, each of which demands peculiar contrivances.

4509. In considering the form and general arrangement of kitchens, regard must be had to the nature of the establishment, and the kind of cooking to be performed, since the apparatus necessary for a small family, where economy of expense and house room is a material object, ought to be very different from what are required in the kitchen of a person of large fortune, or in a public establishment.

4510. "*The distribution of a kitchen*," Count Rumford observes, "must always depend so much on local circumstances, that general rules can hardly be given respecting it: the principles, however, on which this distribution ought in all cases to be made, viz., convenience to the cook, cleanliness, and symmetry, are simple, and easy to be understood; and in the application of them the architect will have a good opportunity of displaying his ingenuity and showing his taste. Should he condescend to consult the cook in making these arrangements, he will do wisely, on more accounts than one." He observes farther, "Cooks, in general, are averse to all new inventions; and this is not surprising, and ought by no means to be imputed to them as a fault. Accustomed *to work with their own tools*, they naturally feel awkward and embarrassed when others are put into their hands: and to this we may add, that there is always a degree of humiliation felt by those who, after having been accustomed to consider themselves, and to be considered by others as masters of their profession, are required to learn anything new, or to do anything in any other manner than that in which they have been always accustomed to do it, and in the performance of which they have acquired praise. It will not, however, be difficult to convince those of the profession who are possessed of a good understanding, and are above low and vulgar prejudices, that certain alterations proposed will meet with their approval *when they become better acquainted with them.*"

4511. *With respect to the various operations of cooking*, Dr. Prout observes that "they are preparatory to the solvent action of the stomach. Of these operations, man's nature has taught him to avail himself, and they constitute the chief means by which he is enabled to be omnivorous; for, without such preparation, a very large portion of the matters which he now adopts as food would be completely indigestible." The same eminent physician considers cooking as operating upon our food much in the same way as the digestive organs in the commencement of their operation: and he says farther, that "in some individuals the powers of digestion are so weak, that the stomach is almost incapable of dissolving solid food of the most simple kind; and that a crude diet of the flesh of animals in a hardened state, 'from bad cooking,' is little else than poison." He adds, "the culinary art engages no small share of attention among mankind; but, unfortunately, cooks are seldom chemists; nor, indeed, do they understand the most simple of the chemical principles of their art. Hence their labour is most frequently employed, not in rendering wholesome articles of food digestible, which is the true object of cooking, but in making unwholesome things palatable."

4512. *As an illustration of the power of cookery, it may be observed that the alteration produced in the qualities of substances by the application of heat* is remarkable. The cassava root, when raw, is a fatal poison to man and beast; but, prepared by fire, it is not only innocent, but forms the common food of the West Indians. The strong odour of the onion is destroyed by boiling. The root of the wake-robin has a juice that will blister the skin; but when boiled it is as mild as the potato. Mushrooms have little taste when raw, but become very savoury when cooked. The raw potato is ill-flavoured, extremely indigestible, and could not be eaten as human food unless it was cooked; but by roasting or boiling it becomes farinaceous, sweet and agreeable to the taste, wholesome, digestible, and highly nutritious. Coffee is disagreeably bitter in its raw state, and the fine aroma for which it is distinguished is entirely the result of the process of roasting. When, in the preparation of bread, considerable heat is applied to the dough, a complete change is produced in its chemical properties; the raw substance differs entirely from the flour: it no longer makes a tenacious paste with water, nor can starch and gluten be any longer extracted from it.

4513. *The application of considerable heat to raw animal food by any of these processes produces in it several chemical changes.* Much water is evaporated, the muscular fibre is rendered opaque by the coagulation of the albumen, and it becomes likewise more tender; the gelatin, which is never liquid in the raw state, is rendered soluble; the fat is partly liquefied, without being melted out of the cellular substance.

4514. *By applying heat to vegetables*, the more volatile and watery parts are, in some cases, dissipated. The different principles, according to their peculiar properties, are extracted, softened, dissolved, or coagulated; but most commonly they are changed into new combinations, so as to be no longer distinguishable by the forms and chemical properties which they originally possessed. Raw vegetables contain much free acid, a great part of which counteracts the digestive functions: the heat of the cooking processes destroys this acid, partly by extraction, and partly by altering its nature: boiled vegetables, therefore, contain little or no acid. By heat, sugar is often formed, as in the case of apples, and new and agreeable flavours are developed: the alimentary properties have been improved, the farinaceous matter is rendered soluble, and the vegetable fibre is softened. Numberless other instances might be mentioned of the influence of heat upon the nutritive properties of substances employed as food.

4515. *The whole subject of food, and its preparation by cookery*, are, as we have before more than once stated, so dependant upon the chemical history of the various substances employed, that it is impossible to study them advantageously without reference to that science; and it is for that reason we have endeavoured to prepare the reader for our present section by some preceding ones. Cookery, indeed, may be considered, in some respects, as a branch of practical chemistry. On a general view, we may divide the various processes of the cook, as generally practised in England, into roasting, baking, broiling, frying, boiling, and stewing.

CHAPTER II.

RATIONALE OF THE SEVERAL PROCESSES EMPLOYED IN COOKERY.

4516. Without entering into those minute details which will be given in another part of this work, entitled "Directions to the Cook," Book XII., Sect. III., we shall shortly describe the rationale of the various cooking processes, and what are the leading circumstances which distinguish them from each other; at the same time, we shall take the opportunity of pointing out the principal chemical changes which they severally produce upon the substances subjected to them. We shall afterward describe the utensils employed in the several processes.

Roasting.

4517. Roasting, as it is usually practised, is fixing meat upon a spit, or suspending it before a fire, and causing it to move round; but this motion is not essential to the process of roasting. It is sufficient that all sides of the meat should be, by some means or other, exposed to the radiant heat of a fire, while, at the same time, a current of air passing over the meat carries off all the steam and other volatile substances that are raised by the process. This species of cookery is therefore divided into roasting before an open fire, and roasting by enclosing the meat in a heated vessel, furnished with a contrivance by which hot air can enter and pass out again, such as the *Rumford roaster*, to be afterward described. In both cases the principle is the same, and also the effect produced.

The first change in roasting is the melting of the fat exposed to the heat of the fire, while, at the same time, the watery fluids on the external part are converted into vapour; but, as the heat penetrates deeper into the meat, the juices undergo important alterations. The gelatin, which, in the raw state, was partly solid, is now liquified, and forms the gravy, which acquires an agreeable taste from its union with the ozmazome; while, at the same time, the albumen of the muscular fibre coagulates by the heat, and acquires a firmer consistence. The change takes place first on the outside, and it requires a considerable time before the heat can penetrate completely to the centre of the meat; but it does so, at last, gradually, and the steam which is formed in consequence, coming from the interior, and bursting out upon the surface, breaks and rends the fibres of the meat, loosens their texture all through the mass, and permits some of the gravy to come out and fall into the dripping-pan, together with the melted fat. As the loss of this would render the meat less sapid, it is continually returned upon the joint by a long spoon, being seasoned with a little salt, a practice well known by the term *basting*, without which a good roast cannot be effected. Towards the middle of the process, the intense heat begins to carbonize the outside, so as to form a kind of crust, which is prevented from increasing too much by turning round and managing properly the heat of the fire, and by repeating the basting sufficiently often. Dredging a little flour on the meat, to cause a froth, is the last part of the process. The dripping-pan should be kept perfectly free from coals or ashes falling into it.

4518. The process of roasting before the fire with a spit is performed in England with admirable dexterity, and little seems to be wanting in this respect by an experienced cook; but it must be observed that it is one of the most difficult processes she has to perform, and that vigilant attention, with much practice, are necessary to make a good roaster. Minute directions for roasting will be given under the Section "Directions to the Cook," Book XII., Sect. III. The following observations are of a more general kind. Managing the fire well, so as to have it clear in front, to get as much as possible of the radiant heat, is essential to success. A screen, covered with tin, is useful, both to reflect heat upon the meat, and thus to save fuel, while, at the same time, it keeps off the draught of cold air that comes to the fire. To roast meat well, it is essential that the fire should not be too fierce at first, otherwise the joint will be scorched: it is usual to keep it, at first, at a greater distance from the fire. The cook is enabled to tell when the meat is sufficiently done, partly by its appearance, and partly by the time it has been roasting.

The meat should not be too long exposed even to a moderate heat, as that would dissipate all the juices, while it coagulated the albumen, and would dry up the muscular fibre. The sapidity and completeness of the roast depends upon the preservation of the juices, and that exact alteration of the exterior surface which is just sufficient to brown it, and thus develop, or, rather, form, by a partial decomposition, the principle called ozmazome, on which the particular flavour of roast meat depends. It is proper here to state that, in many contrivances for cooking, merely enclosing the meat in a heated part of an apparatus, without any current of air passing through it, is improperly termed roasting; whereas, as will be more particularly explained hereafter, it is only *baking*.

Occasionally large Quadrupeds, such as a Bullock or Sheep, are roasted entire.—Among the Jews, the Paschal lamb is obliged to be roasted whole. It may be found difficult for an English cook to bring a whole lamb well dressed to table, but in the East it is not at all uncommon to roast a sheep entire; and those who have not seen it can scarcely imagine how well such a mass of meat may be so cooked. Thevenot says, in his "Travels," that "it is common in Persia to perform this species of cookery. It is done in an oven, which has an opening at the top; after this has been well heated, the meat is hung up in it, and a dripping-pan put under to receive the fat; in this manner it is well done on all sides." The Armenians wrap the sheep in its own skin, and surround it with burning coals. M. Blaquire informs us that in Greece he has seen a whole sheep or lamb turning before a huge fire of wood; this was common among the shepherds. A stake was passed through the carcass, being supported upon two forked sticks stuck in the ground. When the roasting was completed, the animal was carried away and placed against a tree, where it was cut into pieces. Meat is often roasted whole in Italy, and cut from the spit and sold in the market-place.

4519. *It is sometimes necessary to intenerate, or make tender*, meat or poultry that is either fresh killed, or that is naturally tough from age. If there is time, hanging it up a sufficient time has the desired effect, as we have already explained under "Preservation of Food." Whatever accelerates incipient putrefaction serves to render meat tender. It is a well-known fact, that a fowl of any kind, not many hours killed, will become as tender, if buried five or six hours in common garden soil, as if it had been kept above ground two or three days. Fowls newly killed, and dressed before they are cold, and, consequently, before the fibres become rigid, are always tender, as are all the internal parts of animals.

Broiling.

4520. Broiling is a quicker kind of roasting, by putting the meat *over*, instead of before the fire. For this purpose, to prevent smoke, the first should be very equal and clear, and the meat must be turned often, using a peculiar kind of tongs for the purpose, not a fork, which lets out the gravy. As the outside albumen is set firm almost immediately, it prevents much of the internal juices from escaping, and hence the great sapidity of meat well broiled, which is justly esteemed one of the best modes of cooking. Broiling is a simple mode of cooking, often best suited and most acceptable to the fickle appetite of the invalid; and it is recommended by comfort and economy to solitary diners and small families, as affording a means of dressing a small quantity of meat *hot* as delicately as the largest quantity. The English beefsteak and mutton chop are celebrated all the world over, and there are many other excellent things which are done best in this mode. Broiling has likewise the recommendation of being the most expeditious mode of cooking. Some improvements of the apparatus for broiling will be found in our account of "Kitchen Furniture."

Frying.

4521. Frying is a kind of boiling in oil or fat. As these sunstances are capable of being heated to a much greater degree than water, the necessary change is produced upon the meat much sooner than in boiling in that fluid; this is also, at the same time, effected, in some degree, by the radiant heat from the frying-pan; so that, in fact, the process is intermediate between roasting and boiling, and by the intervention of the iron between the meat and the fire it gets very equally dressed. The best substance to fry with is oil; but good butter, if clarified, answers very well, though, if not clarified, it is apt to burn, and give out an empyreumatic flavour, owing to the milk it contains. Good lard, if quite fresh, will do very well. It requires some nicety to make the oil of the proper degree of heat· if not hot enough, the fry will be merely boiled or sodden ir fat, and not fried; and if too hot, it will be scorched before it can be heated through. Frying is often a convenient mode of cooking, as it may be performed by a fire which is not large enough for roasting or boiling. But Dr. Kitchener observes that, though this is one of the most common of the culinary operations, yet it is one that is seldom performed perfectly well.

Baking.

4522. Baking meat in an ordinary oven differs from roasting in this, that the substance is heated in a confined space, and the fumes arising from it are not carried off, no current of air passing through the oven. This is of considerable importance in dressing meat; in baking, the agreeable and peculiar taste of roast meat is not completely developed, a slight empyreumatic taste is acquired and communicated, which a nice palate can almost always distinguish. With respect to the making of pies or pastry, this objection is of little consequence, as the crust defends the articles baked. With this exception, the changes produced by baking are nearly the same as by roasting.

Notwithstanding the objection we have mentioned to meat baked in the ordinary baker's oven, yet for those whose palates are not sufficiently delicate to perceive the defect, this mode of cooking has many advantages of economy, both of time and expense; indeed, a careful baker, who will take some trouble in keeping the inside of his oven perfectly clean, may avoid much of the usual defects; and the oven has been significantly termed "the poor man's kitchen."

The following directions for baking meat are from the excellent manual by Mistress Margaret Dodds:

"The baker's oven, or the family oven, may often be substituted for the cook and the spit, with greater economy and convenience; and for some particular joints and kinds of viands it is even more suitable. A baking-dish ought to be in the form of a trough, and at least six inches deep, that the meat may, in fact, stew in its own juices, as it gets little or no basting; but a *pig* must be baked in a shallow tin dish; the dripping-pan of a bachelor's or Dutch oven will answer very well. Prepare things to be baked as for roasting, but season more highly. A *fillet* or *breast* of veal, if not very highly fed, will bake as well as it will roast. The oven is equally suitable for a *leg* of pork, but a *loin* requires to be sweated in roasting; it is too greasy when baked. A *pig*, if not very old, and if the baker is careful to anoint the crackling as in roasting, bakes very well. His ears and tail must be put in buttered papers, if you would hope even to see them returned from the oven. Geese and ducks may be baked, if not old and rank; in which case they must be sweated in roasting before the fire, to overcome the flavour. A *leg* of *mutton*, with potatoes parboiled and peeled, and an onion shred, makes, when baked, an excellent plain family dish, the mucilage of the potatoes combines so kindly with the fat of the meat. The noble *sirloin* disdains to be cribbed in the oven; but a *rump of beef* slightly salted for a few days, washed, highly seasoned, and baked with plenty of butter in a deep, covered vessel, is esteemed a delicacy. A *hare* or *rabbit* may be baked, allowing pieces of butter in the dish, and putting a large piece or a rich stuffing into the inside of the animal. Herrings, sprats, salmon, haddocks, and eels may all be highly seasoned and baked with advantage. Bakers' ovens have one great drawback; they are accused of being real sponges for gravy, so that they often indemnify the baker's apprentices for the trouble saved to the cook. Besides, meat is seldom got home in season from these wholesale receptacles for all manner of joints. Hams are often soaked and baked when they are used in great quantity, and when the object is to cut thin. Fish, if baked, must have plenty of butter." It is to be observed that most of the last-mentioned evils may be avoided by having ovens at home.

4523. *In baking pies*, in particular, the state of the oven should be attended to. Almost every oven has a temperament of its own. Puff paste requires rather a smart oven to make it rise light. Raised paste must have a quick oven. Practice and observation are very necessary in the management of an oven.

4524. *Among the singular methods of baking*, we may mention that which was originally practised by the natives of Otaheite when they were first discovered by Captain Wallis. They dug a pit in the ground about a foot deep, and a yard across; then, having paved the bottom neatly with clean pebble-stones, they made a fire in it with dried leaves and the husks of the cocoanut. When the stones were sufficiently heated, they took out the embers and raked out the ashes, and then covered the stones with a layer of green cocoanut leaves. The animal to be roasted, perhaps a small hog or a dog, was carefully wrapped up in the leaves of the plantain and placed in the pit, where it was covered over first by the hot embers, and then with bread-fruit and yams wrapped up in the same kind of leaves. Over the whole was spread the remaining embers, mixed with hot stones and cocoa-tree leaves; and, lastly, all was closed up with earth to keep the heat in. After the meat had remained in for a time proportioned to its quantity, it was taken out well dressed, tender, and full of gravy. Captain Wallis thought it was better dressed in this way than in any other Captain King informs us that the same method is still practised by the inhabitants of Chiloe in cooking the excellent shell-fish that abounds in that island.

Boiling.

4525. Boiling consists in keeping the food for a sufficient time in water heated to the boiling point; if the water does not quite boil it is called *simmering*. This mode of cooking is so common a process, and so familiar to every one, that (as Count Rumford observes in his Essays), "few probably take the trouble to inquire how, or in what manner, the effect is produced. The cook knows from experience that if his meat remains immersed in boiling water a sufficient time, it will be *done*, as it is called in the language of the kitchen; but if he be asked what is done to it, ten to one but he will be embarrassed to find a satisfactory answer."

In boiling the flesh of animals, considerable chemical changes are effected. The gelatin, which is always more or less solid in the raw meat, is dissolved by the water, while, at the same time, the albumen, a principle analogous to white of egg, and which is soft in the raw state, is consolidated. When the boiling has been effected by water quite at the boiling point, and the boiling carried on very fast, this is apt to wrap up the fleshy fibre, cause the albumen on the outside to set solid, and to prevent the access of the heat to the interior: hence boiling fast hardens the meat; and when cooked in this way, it will be too much done on the outside, while the interior will not be done enough.

The albumen begins to coagulate at 164°, and at 212° becomes firm. In large concerns, if various-sized joints are boiled together, the small ones will be done before the large; for the time of boiling a joint must be proportioned in some degree to its size. A degree of heat somewhat under 212°, or *simmering*, is most proper for making meat tender. Meat, to be well boiled, should be put into cold water, that the heat may penetrate gradually to the centre; but there are a few exceptions to this rule; fowls and white meat generally require the water to be a little warm. Soon after the boiling commences, a scum arises, which consists of a portion of the albumen with some fat from the outside; this is to be carefully skimmed off.

4526. *In Book II., Chap. I., on "Heat," we gave an explanation of what constitutes boiling properly;* namely, the conversion of water into steam by its being heated to 212°; and we showed that water cannot be heated higher in open vessels; all fuel employed to raise the heat above that point is wasted in merely raising steam. It is very important that all cooks should be thoroughly acquainted with this fact; some imagine that by using much fire, and making the water bubble much, it is made hotter in proportion to the noise and motion it makes. Using much fire will cause the water to evaporate, or boil away faster, but it will be no hotter; and as the cooking of the meat properly depends upon the temperature, and not the quantity of the water, the meat will not be done any sooner by boiling fast; on the contrary, in many cases, it will be hardened, as was explained above, and will be longer in doing. By too rapid boiling, not only is the meat rendered harder, but much of its savoury juices are thus evaporated and lost. The great art in boiling, therefore, for economy and good cooking, is to keep the water *just under the boiling point;* and after it once boils, it is amazing how little fuel will effect this; all beyond that is waste.

4527. *Large joints of meat,* as rounds of beef, hams, legs of mutton, &c., are best boiled in a copper, or some vessel over a closed fire-place, as it is easier to regulate the heat in this manner than with a kitchen range; on this account, boiling by means of steam is advantageous for economy. In boiling in water, it is sufficient if the joint be quite covered with it; there is nothing gained by a larger vessel; indeed, when that is small, the liquor becomes a kind of broth that may be useful. As the water wastes by evaporation, it must be replenished by the addition of some cold water, but better by warm water, if that is at hand.

4528. *In giving directions for boiling vegetables,* there is sometimes a little confusion, some recommending soft, and others hard water. This can only be cleared up by attending to the chemistry of the subject. Soft water has a greater solvent power than hard; and when the object is to extract the juices of vegetables, soft water must be used; as, for instance, in the making of tea or barley-water; but when the juices are not to be extracted, but preserved in the vegetable, then hard water is proper enough, as containing salts which lessen its solvent powers; accordingly, we observe that the cook throws a handful of salt into the water in which she boils her vegetables, which has the effect, although probably she is not aware of it, of making it hard. Vegetables, to be digestible, should be well boiled; and some recommend boiling them in two waters. An analogous observation is made in boiling meat, which is more juicy and tender when hard water is employed than when soft is used, because the solvent power of the latter extracts too much the juices of the meat. With respect to fish, as firmness after boiling is a desirable quality, hard or salt water is decidedly the best; and the cooks put salt into the water to prevent the fish being soft.

4529. ***Boiling, although the simplest mode of cooking, was probably not the first invented.*** To make water hot enough for boiling requires vessels to contain it that will resist the fire. It is remarkable that the inhabitants of the Pelew Islands, when discovered by Captain Wilson, though they baked their meat and fish, were not only unacquainted with the art of boiling food, but were ignorant that water could be made boiling hot, having no vessels in which it could be heated. Some nations, as the Esquimaux, have, however, found out methods of boiling water by hollowing out vessels in a natural substance called potstone, and others have contrived to boil in wooden vessels by throwing red-hot stones into the water.

Stewing.

4530. Stewing differs from boiling in this, that the heat is never to be raised to the boiling point, but only to a very gentle simmering, with a very small quantity of water. Of course, it requires much longer time to cook in this manner; but in stewing, the texture of meat is rendered more tender; the gelatinous parts are more completely dissolved; and instead of a considerable part going into the water, as in boiling, the whole of the juices are preserved in the stew, which is therefore very nutritious. Dr. Prout is of opinion that one of the operations of the gastric fluid is not only to dissolve the aliment taken into the stomach, but to cause its combination with water preparatory to the decomposition which it is to undergo, in order to be separated into those elementary principles from which new combinations are to be afterward prepared by the animal organs; now the process of stewing effects a good deal of this, and therefore leaves less for the operations of the stomach. Stewing is, therefore, found to be not only a very perfect mode of cooking, but also very economical, because a very small quantity of fuel, properly applied, is sufficient to keep up the simmering for a great length of time. In Continental cookery this method is very much practiced, and some of their contrivances are highly deserving of imitation, particularly by the working classes, and others, with whom economy of fuel and time is an object.

Soup.

4531. *In treating, in this place, on the making of soup,* it is not our intention to encroach upon the province of the cook, to whom practical directions, in a future part of the work, will be given for preparing various dishes of this sort. Our object at present is to consider it generally as a particular mode of cooking, and chiefly to point out some chemical principles connected with it, which should be understood by those who are desirous of examining the subject with a view to public objects.

4532. *Soups may be described* as decoctions, more or less strong, of animal and vegetable substances, generally of meat with vegetables, and seasoned with salt, spices, &c. They may be made in an infinity of ways; there is no end to the combinations of meat, fish, vegetables, spices, and mucilage, with water; but of all meats for making soup, beef is esteemed one of the best.

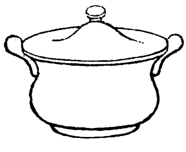
In our description of boiling and stewing, we stated that the gelatin of raw meat is softened by the heat, and is dissolved by the water; but not so the albumen, that being insoluble in water. Soup, therefore, contains the first of these principles, but not the latter, which remains attached to the meat. Besides the gelatin, soup made with vegetables contains also the soluble principles extracted from them, of which mucilage is the most abundant. Both the gelatin and the mucilage combine readily with water, and likewise with each other; but the fat of the meat, which melts with the heat, will not, as is well known, unite readily to water; by means of mucilage or starchy matter, however, oil and water are made to unite, as happens in what is termed by apothecaries an *emulsion*. Thus, almond emulsion is formed by beating up almonds with water or some other fluid; the oil of the almonds is made to combine with the water by means of the mucilage and starch of the almond. In the same manner, much of the dissolved fat in soup is made to unite, and prevented from rising to the surface, by means of thickening added, which consists of flour, rice, oatmeal, or some such material containing starch and mucilage; and thus a good deal of the fat is made to unite with the soup; what refuses to do so, and rises to the surface, should be skimmed off. Dr. Kitchener recommends, in order to save time, that the soup should be made the evening before it is wanted, and when it is cold the fat may be removed from the surface, which, when clarified, is useful for all the purposes of dripping; and Beauvillier observes that this is the best of all the fats used for frying.

4533. *In making soup, the operation should be conducted very* slowly, to give time for the above combinations to take place, and the heat should always be under the boiling point of water, or what is termed simmering.

4534. *It is the opinion of physicians that the nutritive powers of soup have been overrated* by Count Rumford and others, and likewise those of jelly prepared from animal substances, which consists of coagulated gelatin. A very small quantity of solid gelatin, when dissolved in water and cooled, causes it to gelatinize, or set into a jelly; and an erroneous estimate has been formed of the strength of soups by observing their forming a jelly when cold. Gelatin, likewise, is considered by Dr. Prout and others as less nutritive than albumen; but it is the first only that is found in soups, as we have stated; the albumen is retained in the meat. Hence soups, generally speaking, cannot be considered so nourishing to stomachs that can digest solid food; but as gelatin can be digested by persons of weak stomachs, who cannot take more substantial sustenance without inconvenience, soups are very proper for certain invalids. Notwithstanding these medical opinions, which are, no doubt, correct, we have the examples of France, Germany, and other Continental nations, as well as Scotland, in favour of the nutritive power and wholesomeness of this kind of cookery, and there is no doubt that the converting a small quantity of animal food into soup with vegetables is by far the most economical way of using it; and it is to be wished that the strong prejudice that prevails in England against it, particularly among the working classes, was removed.

4535. *The bouillon of France* is a kind of soup, or stew, well known to every family there by the term *pot au feu*, and forms the dinner, and often the breakfast, of a large proportion of the inhabitants of Paris. The manner of preparing it is as follows: An earthen pot, with a cover, called a *marmite* (*fig.* 626), is provided, made to hold from one to seven pounds of meat. A sufficient quantity of lean meat (*bœuf maigre*), usually part of the leg or shoulder, according to the family, is put into this vessel, which is then filled up with cold water, say about five pints of water to one pound and a half of meat. The pot is then placed on the hearth close to the wood fire, and generally upon the hot ashes. When it begins to simmer, or boil gently, the scum which is thrown up is carefully removed from time to time with a spoon, which requires three quarters of an hour before the whole is thrown up, and the meat and water cleansed from every impurity. A carrot, half a parsnip, a turnip an onion, a little celery, or, in short,

Fig. 626.



any vegetables in season, are then added, together with salt and spice. After these additions, the pot remains covered at the fire, and is kept just simmering for six hours more, hot water being supplied in the room of what is evaporated. Length of time appears to be essential to the perfection of this soup; and all who are acquainted with French soups acknowledge their excellence.

4536. *Soup can be made from bones alone*; and though this information may not be of much importance in English domestic economy, where it is seldom practised, still it is an interesting subject, and some useful application may be made of it in certain situations. The composition of bone has been described in Book VII., Chap. II., as consisting of a solid form of certain earthy salts, chiefly phosphate of lime, enclosing a little cartilage and abundance of gelatin.

4537. *Cold water has scarcely any action on bone*; but by maceration in water a long time, the texture becomes more loose and open, and the gelatinous part becomes gradually softened.

4538. *Boiling water acts considerably upon bone*, when reduced to small pieces by rasping or bruising. The first effect is to dissolve and separate the natural oil, which rises to the top, and when cold concretes to a suety fat. The water dissolves a portion of the gelatin, which composes a very considerable part of the substance even of the driest and most compact bones.

M. Pelletier made some accurate experiments on this subject. He macerated six pounds of dry bone shavings, procured at the button-mould makers, for two days in cold water, and then boiled them for nine hours in twenty-four quarts of water. The produce was a very strong, clear jelly, and at the bottom of the vessel was an earthy residue. By subsequent boiling, the jelly became so stiff, when cold, as to bear being cut up into firm slices, which, when hung up on strings in the air, dried in a fortnight into glue of a good quality. The dried glue weighed fifteen ounces and a half. Fifty pounds of ivory shavings gave nine pounds and a half of clear glue. These facts are sufficiently known to many practical economists who are in the habit of preparing jellies from ivory turnings and shavings; and it is a matter of common observation that bones contribute, when boiled with meat, or in soup or gravies, to the richness of the liquor; but it is not commonly known how much gelatin may be extracted from all bones, even the hardest and driest. This gelatin, when dried, may be preserved unchanged for years.

The quantity of jelly is much increased by giving the water by which it is extracted a higher degree of heat than the boiling point; or by reducing the bones to a fine powder, and using repeated coction and pulverization.

The former method was used by Papin in his *digester*, the latter mode was brought into notice by M. Proust. No method extracts the jelly so completely as long boiling in Papin's digester with a very great heat; but the jelly which remains in the water, and the oil which swims on the top, are found to have acquired a burned, unpleasant taste. The method of Proust is preferable; chop the bones into small pieces, and extract the fat in the way mentioned above; then dry the bones, and powder them by some pretty strong mechanical power; boil them with about ten times their weight of water for some hours, till half the water is wasted, more or less, according to the kind of bone, the joint and thick bones making a richer jelly than the thin bones. This proportion of water is sufficient to leave a jelly of about the same richness as would be produced by one ounce of portable soup dissolved in thirty-one ounces of water. The extraction is much assisted by using a close lid, but not fastened down as in a digester; uncooked bones are here understood. The bones of boiled meat still contain a great deal of nutriment, but roasting renders them unfit for this purpose.

4539. *The extraction of the gelatin from bones is now performed in France by another process*, namely, by dissolving all the earthy salts by an acid, leaving the whole of the gelatin. When bones are steeped in diluted acid, as the muriatic, a slight effervescence is perceived, and they are rendered soft and flexible by the gradual abstraction of the earthy basis, or skeleton, which we have said is chiefly phosphate of lime, that becomes dissolved in the acid. The residue is a spongy substance retaining the form of the bone, and consists of the gelatin and cartilage which had originally filled up all the minute cavities of the bone. Nearly the whole of this may be dissolved in boiling water, and yields a solution possessed of all the properties of gelatin. The cartilage which remains undissolved by the water appears identical with coagulated albumen, or white of egg.

A very nutritious kind of ship's biscuit has been made of this gelatin and flour.

4540. *Soup made of gelatin from bones* was used some years ago in the hospitals of Paris; and, notwithstanding the public opinion against it, was said to be sufficiently wholesome; but of late its character has declined, and it is not considered nearly so nutritive as soup made in the ordinary way from meat. In fact, as has been stated, gelatin has of itself but little nutritive power; and it was owing to this having been overrated that many errors respecting soup were propagated. We are the more desirous of pointing out the inferiority of this preparation of soup, lest any persons connected with public establishments might entertain erroneous views on this subject.

CHAPTER III.

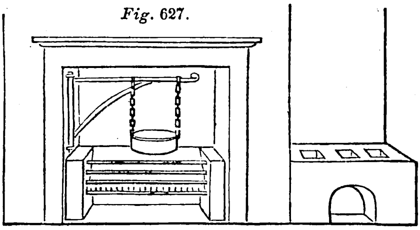
CULINARY APPARATUS.

SECT. I.—FIRE-PLACE.

4541. In considering the apparatus necessary for cooking, our first attention is necessarily directed to the fire-place.

The usual form of the fire-place of a kitchen in the towns of England about fifty years ago was that of a very large, open chimney (*fig.* 627), in which was a very strong iron grate for the fire, called a *range*; the throat of this chimney was enormously large, and the consumption of fuel immense. To support kettles over the fire in boiling, a crane was placed, moveable upon a centre, to which the vessels were suspended by iron hooks that were made to lengthen and shorten to keep them near or farther from the fire: afterward, to economize fuel, the front bar of the range was made to fold down; and moveable iron cheeks were added, to reduce or enlarge the fire by winding them with a rack and pinion; also a little trivet was placed upon the upper bar, to support a tea-kettle or other small vessel. The consumption of coals, with all these improvements, was still very great, not only in large establishments where much cooking was done, but likewise in families of the middle class, where economy is more an object. When stewing, or what are termed *made dishes*, were required, charcoal stoves were used. These are small square pits sunk in a mass of brick-work, generally at the side of the chimney breast, in which lighted charcoal was put, and over which the stew-pans were placed on trivets. As there were no flues to carry off the noxious gas disengaged from the burning charcoal, the kitchens were rendered very uncomfortable, and likewise unhealthy, when stewing was much employed; and as the deleterious nature of these charcoal vapours was not generally understood, no precautions were taken to guard against their bad effects.

Fig. 627.



4542. *Such was the English kitchen when Count Rumford directed the public attention to the enormous and useless expenditure in fuel, as well as to other matters connected with it.* In Germany he had been concerned in the arrangement of public establishments for the poor, and some of his inventions were put in practice with great success; but the difference in the modes of living in that country and in England prevented these improvements from being easily adopted here, and we have no example in this country of his German kitchens described in his "Essays," which were convenient for the cook, and where the economy of fuel was carried to such a degree as left nothing to be desired. In consequence, chiefly, of the writings of Count Rumford, and the various culinary arrangements fitted up in the Royal Institution, and in other places, from his plans and suggestions, a manifest improvement has taken place among us in this department; and though some of the best of the count's ideas have been thwarted through the interested and erroneous views of individuals, yet much good has resulted from his philanthropic and zealous endeavours to benefit society. A portion of this good consists in his having shown how the principles of science may be applied with advantage to the subject of a kitchen, formerly considered as beneath the attention of the philosopher, and abandoned altogether to tradesmen, whose very limited education disqualified them from understanding this subject properly. Since that time, however, considerable progress has been made in the fitting up of kitchens, and many improvements have gradually taken place: our limits will not permit us here to give their complete history, and we must content ourselves with describing such constructions as are now in general use.

4543. *Kitchen Range.*—One of the improved kind now used is represented in *fig.* 628. This grate contains a partition of iron, *a*, which is moved by concealed rack-work and a

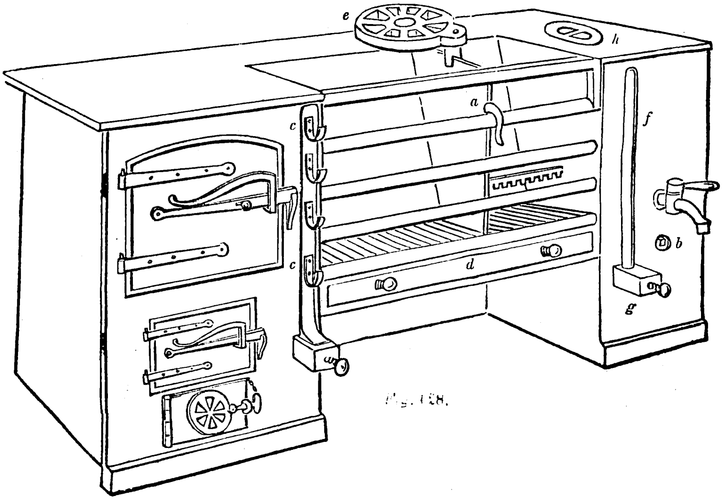


Fig. 628.

key, which goes into the hole at *b*; this is for the purpose of enlarging the fire when roasting is to be done, or contracting it when the cooking is finished. On the top of this partition is a revolving trivet, *e*, to hold a tea-kettle or sauce-pan over the fire. The top bar of the grate folds down, to reduce the height of the fire when necessary, and to support sauce-pans or boilers. A shelf or drawer, *d*, below the fire, may be pulled out to hold the dripping-pan, plates, dishes, or anything where heat is required. On one side of the fire-bars is a series of hooks, *c c*, which one end of the spit rests in, the other end being carried by the chain coming up against the upright round, *g*, *f*, which is attached to a horizontal piece, *g*, that can be pulled out a little to bring the spits nearer or farther from the fire; and the hooks at the other end are also fixed to an upright bar that may be moved out in a similar manner. It is scarcely necessary to mention that the spits are carried round by a jack, and hung at one end by the jack-chain, that works in a grooved wheel fixed to the spit; and that behind the spit is the tin screen mentioned when describing the process of roasting. By this range, also, more than one spit may be in action above one another at the same time. Besides the range itself, which has been just described, there is now frequently attached to it on one side a boiler, *h*, fixed, and forming part of the apparatus: this boiler, extending along the back of the fire as well as on one side, being heated by the fire in the grate, affords a constant supply of hot water, which is drawn off by a stop-cock with a lever handle. On the other side of the range there is an iron oven, heated by a small fire below it, and which, when well managed, serves to bake pastry, &c.

It must be observed that, to bake well in this oven, it is necessary that it shall be so constructed that the fire may circulate over the top of the oven and under the top plate, as well as round the sides and back, in order that the heat may be thrown down upon the things in the oven. When the oven is heated only on one or two sides, and not on the top, it does not perform nearly so well.

The boiler is supplied with water by an oval aperture in the top, closed by a heavy piece of cast iron, fitting it exactly, and having a projection on the under side that goes into a groove. This groove is always full of water from the condensed steam, and the water prevents any steam escaping from the boiler; for, before any can come out, it must make its way through the water in the groove, and also be strong enough to lift up the cover, which, therefore, acts as a safety-valve. To prevent the trouble of supplying the boiler every day with water by hand, some have it supplied from a small cistern in the kitchen with a ball-cock.

With respect to these range boilers, it happens that in a very few years, according to the kind of water used, a stony deposition, of the same nature as the fur of a common tea-kettle, is formed in the inside; and this incrustation, when it arrives at a considerable thickness, impedes the boiling of the water by its being a bad conductor of heat. When this happens, the top of the boiler must be taken off, and the hard incrustation cut off with a chisel. If suffered to remain, not only would the water boil slowly, but the boiler, by getting red hot, would soon be burned out. The best way is every three or six months to clean off the incrustation by scraping, while it is so thin as to scale off.

The boilers, which extend at the back as well as the side of the fire, as represented in *fig.* 628, called by ironmongers *L boilers*, are difficult to get at to clean, and, indeed, cannot be cleaned effectually through the opening usually left; in consequence of which, they frequently burn out at some place and give way. Some, therefore, prefer having the boiler at the side only of the fire, and fasten on the top of it with screws, which, being easily taken out, admit free access to the interior; others omit the oven, and make the boiler extend to both sides of the range, as well as at the back, in which the cleaning out of the boiler is more easily effected by an opening on each hob.

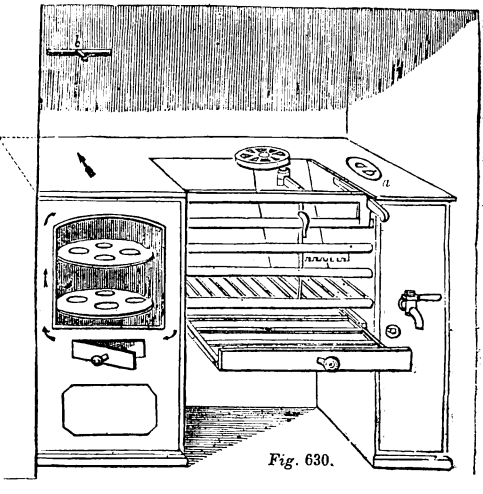

Fig. 630.

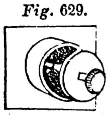
The doors of the fire-place for the boiler and oven ought to fit very close; and there should be a register in the ash-pit doors, which are made best in the form shown in *fig.* 628, by which a very small

Fig. 629.



quantity only may be admitted; this register, which has been long used, is much better than some now employed, as at *fig.* 629, where a circular opening is closed by a flat plate made to move out by a screw.

Other range ovens are heated only by the fire in the range, without any below it, as in *fig.* 630, where there is a narrow aperture in the side of the grate, by which the smoke and heat are allowed to pass beneath the bottom of the oven, in the direction of the arrows, thence round the side farthest from the fire, and over the top, then, lastly, into the chimney flue, there being a damper, *b*, to regulate the draught. Below the oven is an aperture to clean the flue occasionally.

In other ranges, again, there is no circulation round the oven, which is heated only by the fire in the range on one side of the oven, assisted by a *mass of iron* that lies in the fire, and communicates between it and the inside of the oven, thus affording a certain quantity of heat to the latter by conducting it from the fire: in these ovens, though there is no circulation, there is a cavity left all round the side farthest from the fire and the back by the bricklayer, in setting them, which prevents the heat from being absorbed by the walls. But this last kind of ovens, without any circulating flue, do not perform nearly so well, although some ironmongers assert they do, as where the flame and smoke pass all round. Very small kitchen ranges sometimes have an oven and side boiler, both heated by the fire in the middle, without the boiler extending along the back of the fire; but such a range cannot have a partition to wind up to reduce the size of the fire, as the latter must come up to both oven and boiler; these cannot be expected to act so well; but they are useful, and much cheaper.

It is a good method, though seldom practised, to have the side of the oven next the fire made of double iron, with half an inch between the plates, to prevent the too violent heat on that side. By a late improvement, the shelves in the oven are made circular and to revolve, so that the different sides of the dishes placed upon them can be presented in rotation to the hottest part. This is shown in *fig.* 630, where the door is left out to display the shelves.

4544. *In very large kitchens*, where a great deal of cooking is performed, the range is usually made of much larger size, and the bars are of great strength. The boiler is likewise made of wrought iron instead of cast, for greater strength and durability, and placed at the back of the fire only, whence they are termed *back boilers* (see *fig.* 631).

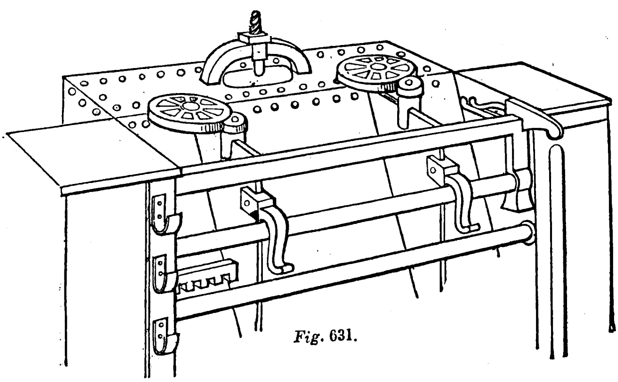


Fig. 631.

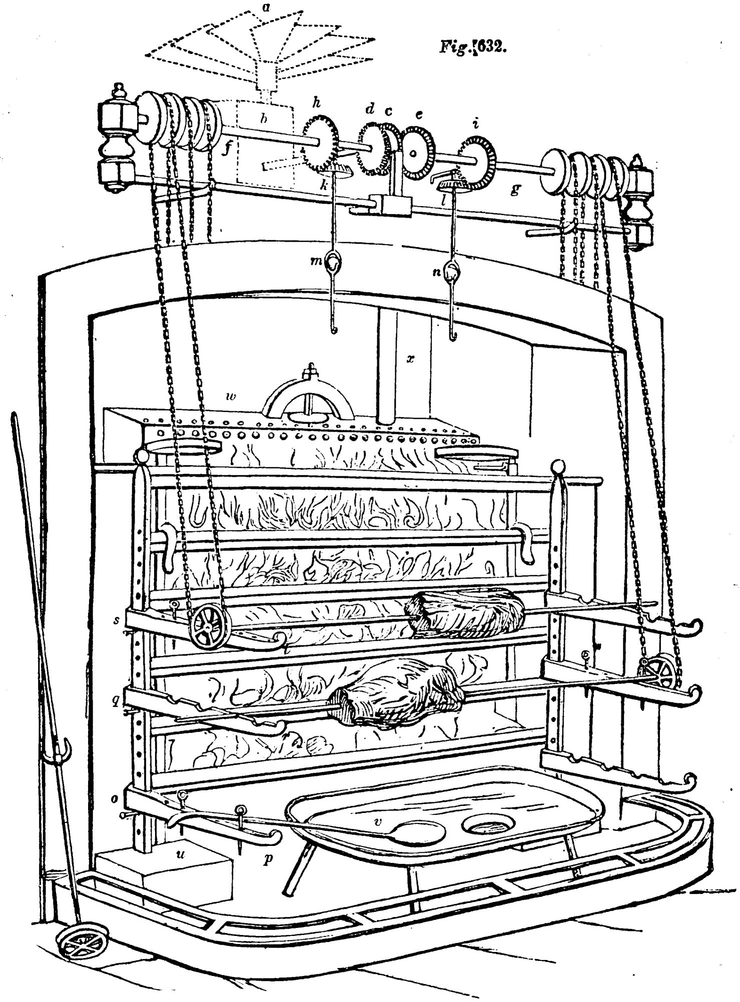
A pipe from the boiler conveys water from it, and it is kept full from a supply cistern A man-hole for cleaning it out frequently is provided at the top, which is secured from the steam coming out, by an arch of iron, and a screw and nut. There are two winding up partitions for reducing or enlarging the fire. *The kitchen fender* is made of strong iron, with a flat double bar on the top; and sometimes there is a pit below the grate for the ashes, covered by a grating to separate the cinders.

4545. *It is commonly stated by ironmongers* that ranges of this kind, with boiler and oven, perform the operations of boiling and baking *without any additional expense or consumption* of fuel. This statement is absurd. The large quantity of iron in the range, and the water in the boiler, absorb heat from the fire; and therefore, with such appendages to the grate, there must be a certain loss or extra expenditure of heat absorbed, which can only be supplied by more fuel than would otherwise be necessary; but in many cases that loss is not to be regretted when put into comparison with the advantage and great convenience of having hot water always at hand without any trouble, together with a hot oven, either to bake in or to keep things warm. The boiler will even retain its heat, in a considerable degree, for several hours after the fire is extinguished.

Fig. 632.



These improved modern ranges are sold at various prices, according to their size, quality, and strength, from two or three pounds to eight, ten, or fifteen.

Fig. 632 represents the *kitchen fire-place at the City of London Club House* in Broad-street. Here there is one of the largest class of ranges, with a back boiler, and a smoke jack which turns six spits occasionally. *a*, the fan wheel of the smoke jack, in dotted lines, is behind the chimney breast in the flue of the chimney; *b* is a box enclosing two bevel wheels, one horizontal on the axis of the fan, and connected with another one vertical, the axis of which comes through the chimney breast, and has on it another vertical wheel, *c*, the latter turning two bevel wheels, *d* and *e*, which are fixed on the long axis, *f g*, that extends across the chimney, and which, of course, is made to revolve. On both ends of this axis is a grooved cylinder, in the grooves of which are chains to go down to the grooves of the wheels attached to the spits. In the wood-cut, two only of the chains are represented in action; the rest are only partly shown hanging down perpendicularly, to prevent crowding the figure. Besides these parts, there is on the same axis, *f g*, two more bevel wheels, *h* and *i*, which turn two smaller ones, *k* and *l*, the axes of which are vertical, and have on them universal joints, *m* and *n*. These last are called by the cooks *danglers*, and their use is to turn, by means of another wire and hook, any smaller articles that may require to be roasted, and for which spitting may not be convenient: the motion of these, of course, will be vertical, as when meat hangs by a string or bottle jack. The supports for the spits, *o p*, *q r*, *s t*, are not attached to the range, as in smaller ranges, but are inserted in two upright standards, which are fixed in masses of iron at the bottom, *u*, which can be moved farther out or nearer to the fire; the supports also, *o*, *p*, *q*, &c., can be raised or lowered. One end of the spit acts against an iron pin, and the other lies in a semicircular notch. *v* is the large dripping-pan with its ladle for basting, having a very long handle, to enable the cook to baste without being exposed to so fierce a heat as proceeds from this range, which is usually quite filled with a dense fire. *w* is a back boiler of wrought iron, from which a pipe, *x*, proceeds to carry hot water to the baths near the bedrooms in the upper stories, the boiler being supplied with cold water by another pipe from the high-service cistern. In the range are two winders for contracting the fire, but which in this place are never used, because the fire, being constantly wanted, is kept up till the evening, when it is suffered to go down, and is then smothered with the ashes. Coke alone is the fuel employed, which makes a very bright and hot fire. In some other large ranges, as that in Buckingham Palace, which is of the same construction, coke only is employed, requiring no renewal for the whole day.

4546. *More examples of kitchen ranges* will be given in Chap. IV.

Sect. II.—Apparatus for Roasting.

4547. Roasting is probably the most ancient mode of cooking, and it was at first performed in the open air by means of large fires, the waste of fuel being immense; a circumstance frequently of little consequence in countries where wood can be always had by the trouble of only gathering, and where sometimes the consumption of it is rather an advantage than inconvenience. But in colder countries, where fuel is scarcer, the operation is performed in the house; and in the oldest kitchens, from the size of the fires used in them, it would seem as if the original process had been partly imitated.

4548. "*In olden time*," says Aubrey, "the poor boys did turn the spits, and licked the dripping-pan, and grew to be lusty knaves." Even dogs were sometimes taught to perform this tedious operation. Afterward the science of mechanics was called into request, and *jacks* were invented. At present, there are two principal kinds of these in common use, *wind-up jacks* and *smoke-jacks*.

4549. *The common wind-up kitchen jack, moved by a weight*, is constructed in the following manner: *a*, *fig.* 633, is a barrel, round which is coiled a line of considerable length, and having one end fastened to a compound pully, *b c*, containing three or four sheaves, to which is appended a weight, which, by descending slowly, moves the barrel round with the proper velocity. The weight and pully are usually kept outside the kitchen, the line passing through a hole in the wall. An endless chain passes round the barrel, *a*, and the spit, *h*, which last, of course, turns with the same velocity as the barrel. To render the motion equable, and to prevent the jerks that would take place should the meat not be spitted quite equally, a fly, *g*, is attached to the machine, to effect the motion of which, a wheel with teeth, *o*, is fixed upon the barrel, and the teeth work in a screw fixed on the upright axis of the fly. When the weight has descended as far as it can, it is again wound up by a handle placed upon the square end of the barrel spindle; but the machine should be so calculated that it should not be necessary to wind it up during one roast. The length of time it may go without winding may be increased by the system of pulleys, or by causing the weight to descend into a small well formed for it. Servants object much to the trouble of winding up this jack, little as that trouble is; and hence smoke-jacks are suffered to supersede them, notwithstanding their simplicity, and being less apt to be out of order.

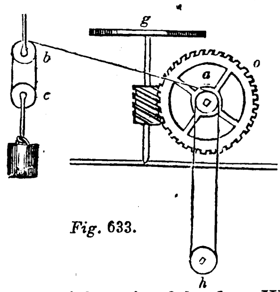


Fig. 633.

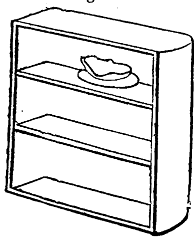
4550. *The smoke-jack*, invented to obviate the trouble of winding up the common jack moved by weights, consists of a horizontal wheel filled with spokes, or radii, of metal, placed obliquely, in the same manner as the sails of a windmill or the little circular ventilators sometimes seen in windows, and turned, like them, by the current of air striking upon them. This wheel is fixed in the inside of the flue, and the motion of its axis is easily communicated to another wheel, to which is attached a chain that goes over one fixed to the spit. A very complete smoke-jack is represented, *fig.* 632.

Notwithstanding that Count Rumford long ago pointed out the waste of fuel occasioned by the employment of this machine, it continues to be as great a favourite as ever. He justly remarks that, to cause the smoke-jack to go round with sufficient force to carry with it its load of meat, it is frequently necessary to make a greater fire than the mere roasting and other cooking requires; hence it is very expensive; and that, besides, it is very liable to be out of order, and is difficult to be got at when it requires cleaning; added to which, it is not unfrequently the cause of smoke; and its situation prevents that cure for smoky chimneys which Count Rumford recommended as the most effectual. That the smoke-jack increases the draught of the chimney, as some ironmongers pretend, is a statement almost too ridiculous to be seriously refuted. The assertion that all the fire that is required to make a smoke-jack perform properly would be necessary in the kitchen for other purposes, and, consequently, that they occasion no additional expense of fuel in roasting, is very incorrect, though a small fire will make it turn when not loaded with the spit.

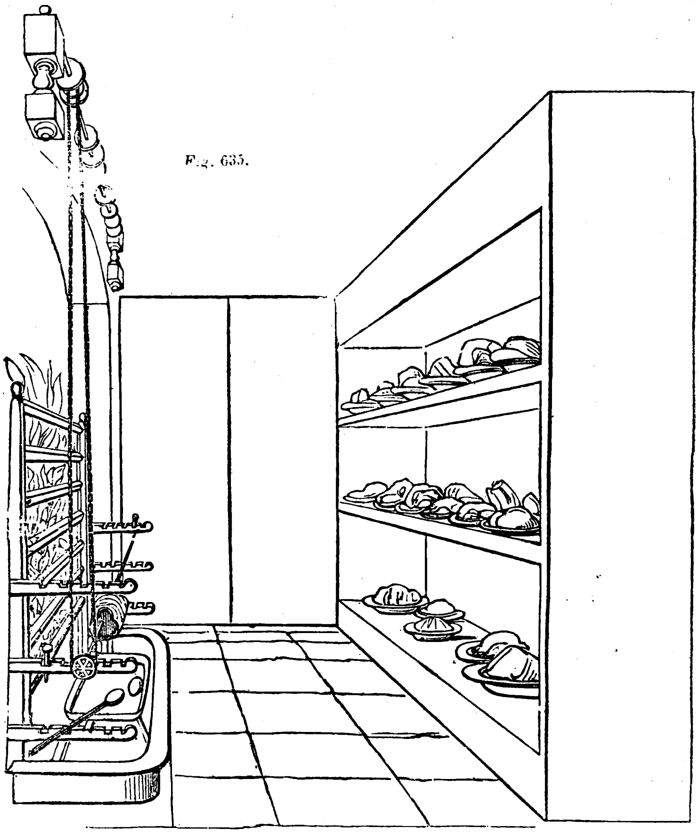
Fig. 634.



4551. *To increase the effect of the fire upon the meat in roasting*, as well as to prevent the radiant heat from incommoding the kitchen, *a screen*, *fig*. 634, is always placed before the fire, lined within with tin plate. This is now generally furnished with shelves to place plates and dishes upon to warm, or to keep the meat hot until it is wanted. On the back of the screen are sliding doors for taking out the dishes.

4552. *The heat from very large ranges would be intolerable to the cooks*, were it not for the screens which are placed before them. *Fig*. 635 represents

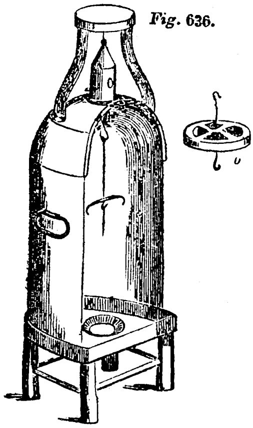
Fig. 635.



that of the City Club House on the side next the fire. It is about seven feet high, lined with tin plate, and has shelves on the side next the fire to place dishes with meat on to keep hot; doors on the back give access to the dishes. It is a great improvement to shut in also the ends by folding-doors, thus entirely enclosing the fire-place. By this means the greatest part of the radiant heat of the fire is stopped from coming into the kitchen. In the wood-cut the doors on the nearest side are supposed to be removed to show the screen; they are only opened when the cooks wish to look in.

4553. *The bottle-jack and niche screen*, *fig*. 636, when well made, is often a useful substitute for the spit. It consists of a spring enclosed in a brass cylinder, and requires winding up every time it is used; the joint is fixed to an iron suspended from the cylinder containing the spring, and this is usually fastened to a niche made of tin, which serves to reflect much heat, that assists in the roasting. At the bottom, on a stand, is a small dripping-pan, or well, to collect the gravy. This apparatus is capable of roasting

Fig. 636.

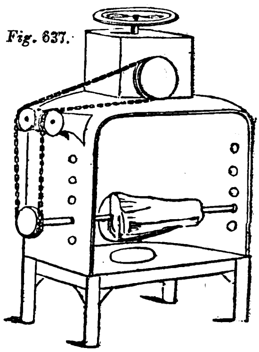


a tolerably large joint; but, if the joint be small and light, a weight of cast iron, *b*, is necessary to be attached, to make it turn more steadily. Some of these are made to go two hours without winding.

Some cooks say that the bottle-jack is best used without the screen, or only one of the common kind, when the fire is large; for, with its own niche screen, the reflection is so powerful that the meat is apt to be dried up too fast. The whole apparatus is extremely useful where the economy of fuel is to be much regarded; for it will roast very well, with attention, when placed before a very small fire, so that, with it, there is never any occasion for a large fire in the range; and therefore it is much used in small families.

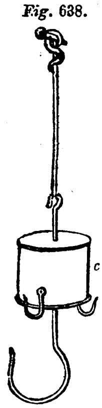
4554. *An improved spring-jack* for roasting, *fig.* 637, has lately appeared, in which the meat is fixed on a spit lying horizontally in the usual manner. A box on the top contains the spring, which carries round a wheel on the front; round this an endless chain passes over two pulleys to the spit, which goes through on the side of the tin screen. By means of several holes, and shortening or lengthening the chain, the height of the spit can be adjusted; and there is a flywheel to regulate the motion.

Fig. 637.



We should not omit the humble string and weight, *fig.* 638, by means of which many a small joint or piece of meat is roasted by the simple twisting and untwisting of a worsted string: *c* is a tin box filled with some heavy substance, and costs only sixpence. This will roast about six or eight pounds of meat, and two smaller hooks are added for less articles. The only objection is the attention necessary, as the string requires a slight twist every five minutes.

Fig. 638.



Roasting, as it is usually conducted on a spit before a kitchen range, consumes more fuel than all the other modes of cooking; and it was from this circumstance that Count Rumford was induced to turn his attention to the means of economizing, without injuring the perfection of the roast.

4555. *One of the principal inventions which he brought to England in* 1795 was a method of dressing meat, at that time unknown here, by which it could be roasted quite as well as is usually done before a large open fire in a kitchen range, by shutting it up in an apparatus, somewhat resembling an oven, that required only a very small quantity of fuel to heat it, with the advantage of a great saving of trouble. Every nice palate can distinguish between meat baked in a common oven and that which has been roasted before an open fire; but the *Rumford roaster* completely annihilated this difference, and no one could distinguish between a joint properly cooked in this machine and one done before a range. In consequence, not only hundreds, but thousands of Rumford roasters were made, and employed in English, Scotch, and Irish kitchens; and it was universally allowed that they entirely answered the desired object.

4556. *The original Rumford roaster* was a cylinder of sheet iron laid horizontally, and set in brick-work, with a small, closed fire-place below it, the smoke and flame passing all round the cylinder, and then descending some way before it passed off into the flue. In the interior there is a dripping-pan, placed upon two long sliders, forming a kind of sledge, which can be drawn out and pushed into the roaster. In this dripping-pan a sort of gridiron is placed, on which the meat is laid; and a little water is put into the pan, on which the melted fat falls, and is thus prevented from being burned; or sometimes an inner pan is put over the water, and receives the fat, which, in that case, will not mix with it, nor yet be burned, because the water cannot be heated higher than the boiling point, which is not enough to burn. It might be supposed that water thus placed within the roaster would have the effect of making the meat sodden, from the steam; but Count Rumford observes that steam itself is always perfectly *dry*, and that it is only when beginning to be condensed by cooling that it becomes moist: as it cannot cool inside the roaster, no such condensation can take place; and, as the dry steam will occupy the upper part of the roaster, separate from the air, it can have no effect in rendering the meat moist. This steam, however, is ultimately carried off by the steam-tube at the top of the roaster.

An essential part of this machine is the contrivance by which a stream of very hot air is made to blow upon the meat, at a certain part of the process, for the purpose of browning it, and giving it the taste peculiar to roasted meat. In the count's first roasters this was effected by means of two tubes of iron placed a little below the bottom of the cylinder opening into the farther end of it, and lying just above the fire, which played upon them and heated them. At the commencement of the process of cooking meat with this apparatus, the outward ends of these tubes are kept closed by stoppers; but, some time before the meat is done, the stoppers are taken out, and then a strong current of air, intensely heated in passing through them, enters into the inside of the roaster, blowing upon the meat; this air passes out through the steam-tube, carrying with it all the steam and other vapour.

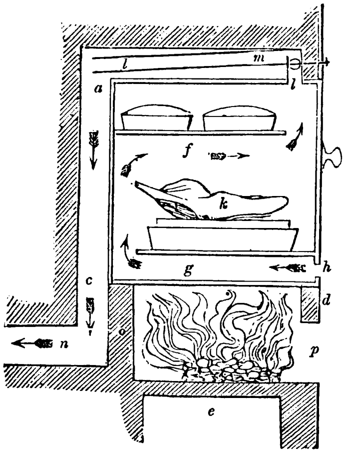
As these tubes, being exposed to a violent fire, were apt to be destroyed in time, endeavours were made to effect the same thing by other means, which were tolerably successful. Instead of tubes lying over the fire, a portion of the cylinder was devoted to this purpose, by making a horizontal division near the bottom, and the portion of the cylinder below this served for the hot air, the front opening into this space being closed by a register. When the roasters were afterward made square, a still simpler method was employed, which continues in use among the ironmongers.

4557. Although we have mentioned and described the proper Rumford roasters, of which we have stated that a great number were executed and put up about thirty or forty years ago, and are particularly described in the count's "Essays," we have avoided entering into more details respecting them, because they are no longer manufactured in the original form, and therefore cannot be purchased. It would also be very difficult now to find an ironmonger who could make one correctly, and perhaps scarcely possible to procure a bricklayer who could be depended upon to put one up without some mistake, thirty years being sufficient to deprive us of those persons who understood them in Count Rumford's time. We cannot, therefore, recommend at present the original Rumford roaster, since, though an admirable invention, yet, if executed by the present workmen, there would be a great chance of its failing, from some cause or other. When the Rumford roasters first appeared, many doubts were entertained with respect to their efficiency. As the meat was shut up in a confined space, in an apparatus having the general appearance of an oven, it was natural enough for some to suspect that it was rather *baked* than *roasted;* and it may be well to mention that Dr. Kitchener, celebrated for his gastronomic acquirements, appears not to have been accurately informed on this point. In his interesting work, entitled the "Cook's Oracle," he observes, "The machines the economical grate-makers call *roasters* are, in plain English, *ovens.*" Now iron roasters are very different from iron ovens; and both were made and sold by "economical grate-makers;" but the only complete iron roaster is that invented by Count Rumford, which was executed and employed in the military academy at Munich previous to 1790. This date is mentioned here, because some persons have, very unfairly, set up a claim to the invention of a roaster of the same kind, although produced subsequently to the count's first visit to England, when he placed several in public establishments in this country; and one may be still seen, though not in use, in the kitchen of the Foundling Hospital.

4558. *The difference between an oven and a roaster is this:* In the former the meat is shut up close during the *whole operation of baking;* whereas, in the latter, the machine is kept closed for a certain time only after the commencement of the operation; but then a strong current of very hot air is admitted into the lower part of the apparatus, which, after traversing below and above the meat, is suffered to escape at the top, carrying with it the steam, and drying up and browning the surface of the meat, which thus does not absorb those empyreumatic particles that are produced in baking. The effect produced in a roaster is, in fact, exactly analogous to what happens in turning the meat before the fire; for it is to be observed that the meat, being placed in the roaster upon a grated slider or drawer, when this is pulled out, it can likewise be basted. Many persons, indeed, who had used these machines, considered the meat dressed in them as peculiarly juicy and well-tasted. When, added to this, it is considered that, instead of the large clear fire necessary for roasting a joint on a spit, two or three pounds of coal will suffice with a roaster, and that, instead of constant attendance, very little here is necessary; that in the processes all accidents by cinders, ashes, or other things falling into the gravy are prevented, and that, instead of the kitchen being made very hot by a large fire, the heat from the roaster is not even felt, it is surprising that cooks have not been delighted with an invention that had so many advantages in its favour. Nevertheless, it must be admitted that many servants, who know very well how to roast with a range, would be at a loss, at first, to manage this machine properly: like the use of every new tool, they must have sagacity and patience enough to discover the best practice, or submit to be taught.

4559. *Apparatus of an analogous kind are at present made by various ironmongers, and termed roasters,* which, though a departure from the best construction of Count Rumford's, are, however, an imitation of them, and depend upon his principles partly for the advantages they possesss over a common oven. They are always square, and of cast iron, containing a great deal of metal, and, consequently, expensive, though durable; and they are usually connected with some other apparatus, as a hot plate, hot closet, &c. These, in modern kitchens, of which we shall give a few examples, are executed by manufacturers in various forms, each having his own arrangements, and are better or worse as the makers are more or less acquainted with the principles on which they ought to be constructed. Some of them, denominated roasters, are not so in fact, there being no circulation of *hot air* within, and having merely an aperture in the door closed by a register, which does not answer the purpose. Others have been invented evidently without the maker understanding the use or intention of the circulation of air. In short, as each manufacturer describes his peculiar machine as his own invention, and as the public has no prototype to refer to for comparison, criticism is evaded. These machines really belong to a class which Count Rumford also invented and described in his "Essays," under the name of *roasting ovens*, which, however, perform very tolerably, and are much employed at present, being found extremely useful in economizing both fuel and labour in public or large kitchens.

Fig. 639 represents a general section of the roasting oven as it is now usually executed, in which many details are left out, and only sufficient is shown to explain the principle. *a b c d* is the body of the iron roaster, which is of a square form, larger or smaller, and set in the brick-work, with a fire, *e*, below it, *b d* being the front of the roaster. The fire which burns on the bars, *e*, ascends round both sides of the roaster in a cavity left between it and the brick-work, passes over the top in a similar cavity, and then descends by the back of the roaster *a b*, in the direction of the arrows, making its exit by the horizontal flue, *n*, that goes at last in the perpendicular flue to the top of the house. It is to be observed that the fire is stopped from passing at once into this flue by the brick-work, *o*. *p* is the fire door, which is of iron, and kept shut, the fire being fed with air from the ash-pit, the door of which has a regulator. Within the oven, *a b c d*, are two shelves, *f*, *g*, also of iron, the lower one being near the bottom. For the circulation of hot air, when required, *h* is an aperture beneath the door of the roaster, having a register to close it when it is not wanted. When the hot air is to circulate, this register is opened, and the air which is heated by the bottom of the roaster turns out at the farthest end of the lower shelf, as represented by the arrow, passes over the meat placed in its pan and gridiron, *k*, ascends through the vacancy occasioned by the upper shelf not reaching to the front, and finally passes off into the tube, *l l*, which can be closed by a register, *m*, moveable by a small rod coming to the front. This hot air then joins that from the fire, and passes into the flue.



4560. *In the management of all the varieties of the roaster*, care must be taken not to employ too much fire: an error which those who are not accustomed to them are apt to commit at first, not imagining how small a fire is sufficient. It is likewise requisite frequently to sweep out, with a wire-handled brush, the flues round them, for which purpose proper openings are left by the bricklayer who sets them, if they are set in brick, or by the ironmonger, if the whole is made of cast iron, which they frequently now are, and which, if not the most economical mode at first, is perhaps so in the end, less repairs being necessary. The inside of the roaster should be kept perfectly free from grease, otherwise the burning of this will give an unpleasant taste to the meat. Since the difference between baking and roasting is, that the latter demands a circulation of hot air round the meat, whereas the former does not, it is obvious that, if the apertures in the square Romford roaster, through which the hot air enters and goes out, are closed, it becomes, in fact, an oven; and hence it can be employed to bake as well as to roast; but it is remarkable, and what could scarcely be expected, it can be made to roast one dish and bake another at the same time. This will be understood by reference to the section, *fig.* 639, where, on an upper shelf, are seen dishes, which may be supposed to be pies standing to be baked, while the joint below it is roasting. This upper shelf is capable of baking, because, as it goes quite to the back, there is no circulation of air round it, the hot air making its exit, according to the direction of the arrows, in front of this shelf and up through the steam tube, without touching the pies, which are therefore surrounded by hot air, *nearly*, but without any current.

4561. Some roasters are likewise made so large as to contain several shelves for roasting, and are contrived so that the current of hot air shall circulate over the different dishes, each being placed in a separate dripping-pan, to prevent the gravy and fat of one dish from falling on another; and these, if well managed, are found to answer.

There is a precaution to be taken in opening the door of a roaster when meat is roasting in it, which ought never to be neglected; that is, to open the steam tube and openings for hot air for about a minute, or while a person can count forty or fifty, before the door of the roaster be thrown open. This will drive away the steam and vapour of the roaster which otherwise would not fail to come into the room.

As it will sometimes happen that the meat will be done before it is time to send it up to table, it may be either taken out of the roaster and put into a hot closet, which may be situated over it, and heated by the smoke from the latter, or it may remain in the roaster till it is wanted, by a particular management. For this purpose, the roaster must be cooled a little, otherwise the meat will be overdone; and this cooling may be effected by shutting the register of the ash-pit; next, opening the fire-place door and the damper in the chimney; then taking out the fire, or covering it up with cold ashes; and, lastly, opening the damper in the steam tube, and openings for the admission of air into the roaster. By these means the heat will soon be driven up the chimney, and moderated till the interior of the roaster is cool enough; and then the meat may be put into it, and all the doors shut.

4562. *It is necessary that the fire-place door of a roaster or oven should fit well;* otherwise the air that enters will probably pass over the fire, instead of through it, and thus carry off into the chimney part of the heat of the fire, and, in fact, act in cooling the apparatus. A single door of iron will let the heat come through it, and the oven will not be so well heated. The door should be of some non-conducting material; either lined with fire-stone, or it may consist of two plates of iron, with a space between to contain confined air. Some have employed double doors, kept an inch or two apart, but so fixed together as to open at once.

4563. *A method of roasting by means of gas flame* will be described under "Cooking by Gas," Chap. III., Sect. X.

4564. *The well-known Dutch oven, fig.* 640, is an extremely useful apparatus for the kitchen of a small family. Its principle is the heat obtained by a strong reflection from the inside, when the oven is placed upon a stand close to the fire. It is usually made with a little dripping-pan in the bottom, and it has a shelf in the middle to place anything upon that requires to be warmed or browned; a small piece of meat, or a bird, may be roasted by removing this shelf, and suspending the article by one of the hooks, which are made to turn to expose the different sides of the meat.

Fig. 640.

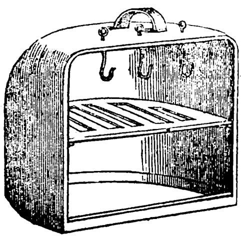


Fig. 641.

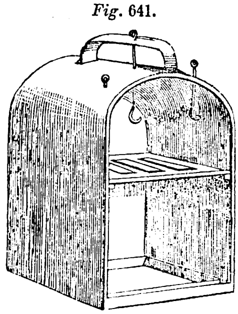
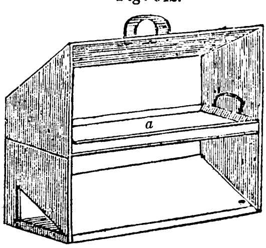


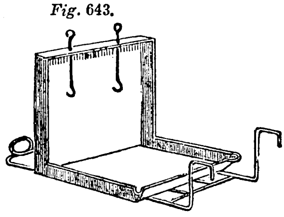
4565. *The Yorkshire oven, fig.* 641, differs from the last in being higher in proportion to its width, thereby giving more room for anything suspended to be roasted; and by a slit in the handle, the meat may be removed farther from the fire, or nearer to it. There is likewise a door in the back for access to the meat. The shelf is only placed occasionally, as in the last.

Fig. 642.



4566. *The American oven, fig.* 642, is an improvement on the Dutch. By means of a bottom slanting upward, and the top slanting downward, the reflection of heat is still stronger. In this case, the meat, or other article, is laid in an iron tray, *a*, which is moveable, and may be lifted out by two handles, the top moving back on hinges; beneath the false bottom is a place for warming plates. This apparatus is coming much into use, being found extremely convenient for roasting and baking bread, cakes, &c.

Fig. 643.



4567. *A tin toaster, fig.* 643, placed upon a stand of strong wire that hooks on the bars of a grate, and made either loose, or to slide backward and forward on the stand, is an apparatus extremely useful, and which may be purchased for eightpence; not only may cheese or bread be toasted, but a mutton chop may be dressed as well by this as by more expensive apparatus.

4568. *A very convenient apparatus for toasting bread and muffins* is represented in *fig.* 644. It is made of tin plate, and placed on a stand before a clear fire.

4569. *Cheese toasters* are represented in *fig.* 645 and *fig.* 646; in the first there is only one tray for the cheese; in the second there are six small trays.

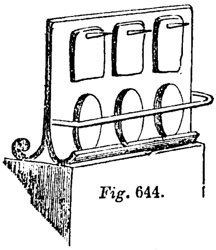


Fig. 644.

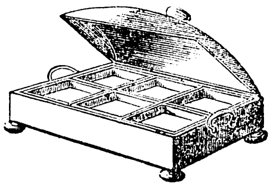

Fig. 646.

SECT. III.—APPARATUS FOR BROILING.

4570. *The common gridiron for broiling* is too well known to require any description. In broiling chops and other fat meat, the flaring made by the melting fat going into the fire is very inconvenient; and to prevent this, some gridirons have grooves in the bars. by which, when the apparatus is placed a little slanting, the liquid fat flows down into a trough at the bottom. These may be seen in daily use in some of the chop-houses near the Royal Exchange; but except these grooves are kept extremely clean, the fat is liable to be burned, and to communicate a flavour similar to that from a frying-pan. Round bars are easier to keep clean than square ones; and when the gridiron is kept upon the slant, with care and atttention, little fat will fall into the fire.

4571. *A broiling stove* (*fig.* 647), made by Mr. Jeakes, Great Russell-street, London, is a great improvement. One of the difficulties in broiling is the keeping the fire perfectly clear, to prevent the meat from being spoiled with the smoke; this difficulty is completely obviated in a very simple manner by this contrivance: A square aperture is formed in a plate of cast iron, *a b*, which is placed upon brick-work, or forms part of an iron body; immediately below this aperture a pit is formed in the brick-work, or the iron, for the fire, having a flue leading from it, at first horizontally, and then upward, terminating in the flue of the chimney. Sliding doors, *c c*, are likewise provided in front, opening into the fire-place. When these doors are shut, and coals or coke are lighted in this pit, or fire-place, the air will draw *downward*, to feed the fire, through the aperture in the large plate, the cover being removed, and when the fire burns well, no smoke will ascend through the square opening just mentioned; there is, therefore, an extremely clear fire to broil over. To support the gridiron at any height, two uprights are placed in the iron plate, with holes, into which projecting points in the gridiron are inserted.

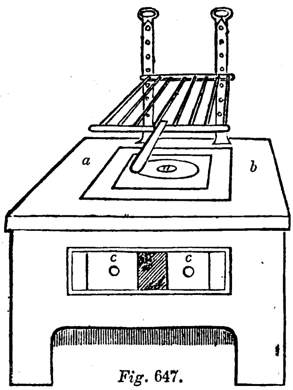

Fig. 647.

When the fire has burned up sufficiently clear, and broiling commences, the sliding doors, *c c*, are opened a little, generally less than is represented in the wood-cut, which, admitting air to the fire in another direction, in some degree checks the draught downward, and therefore moderates the heat. There is also a damper in the perpendicular flue, within reach, by which the cook can regulate the draught, and, of course, the fierceness of the fire.

In the wood-cut, the apertures on the iron plate are represented closed by two squares, one within the other; the inner square is that which is taken out when broiling is required; the larger one is only taken out when cleaning or repairs are required. Within the smallest square is a circular aperture, filled, when not wanted, by an iron disk, as represented in the cut. This last circular aperture, when open, is generally found sufficient, as the heat sent out is intense, and spreads considerably. When broiling is not wanted, the whole of the apertures on the top are closed, as shown in the wood-cut; and the apparatus then serves for a hot plate.

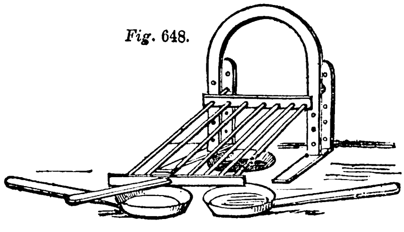

Fig. 648.

Lately an improvement has been made in this excellent broiling apparatus. Instead of the standards being fixed to the hot plate, they are united by an arch, as in *fig.* 648; and the lower part being bent to a right angle, they stand loose by their weight alone, at the proper place, and may be removed when broiling is not required, and the hot plate alone is wanted for boiling or stewing. The best method for using this apparatus is the following:

Instead of keeping the gridiron horizontal, which occasions much of the fat to fall upon the iron, the gridiron should be kept slanting, as in *fig.* 648, by which the fat runs down the bars into ladles placed to receive it; a trough was used at first; but the cook at the City Club found ladles more convenient. We mention this the more particularly, because intelligent cooks are extremely capable of making improvements, when not bigoted, as they too often are, to their own practices. There is another advantage gained by this arrangement, which is, that when meat is on the gridiron, it serves to keep much of the heat from the face of the cook. From having examined the process of broiling by this apparatus, we cannot too strongly recommend it for the cleanness, facility, and expedition with which the process can be performed, as well as the great convenience to the cooks. When broiling is not wanted, a sauce-pan may be kept boiling over this circular aperture; of course, it must be supported upon a little trivet to let the air get down, and the bottom of the sauce-pan not be allowed to cover up the whole aperture. We think it proper, likewise, to mention that, to ensure the right performance of this useful apparatus for broiling, it is by far the most advisable to procure it from the original inventor, Mr. Jeakes.

It is observed by Mistress Meg Dods that "broiling is the most difficult manual office the common cook has to perform, and that which requires the most unremitting attention. She may turn her back upon the stew-pan or the spit; but the gridiron can never be left with impunity." Jeakes's apparatus certainly enables her to attend to this operation more closely than any other, since she is less incommoded by the heat of the fire.

We have represented this broiling-stove by itself, because it may be so executed, and is sometimes done so; but it is frequently also made to form part of a larger hot plate, beneath which the flame passes, and on which various sauce-pans and stew-pans can be placed; and the same fire is sometimes made to heat an oven and a hot closet.

4572. *Fig.* 649 *is a confectioner's stove* and hot plate for boiling sugar, in the establishment of the well-known Mr. Gunter, of Berkeley Square, and which he speaks of as the best for the purpose. This was put up by Mr. Jeakes, and the circular aperture is closed by several rings of iron of different sizes, by which the size of the opening may be varied, and adapted to different vessels. There is likewise a narrow chink, or crevice, immediately beneath the top plate, marked in the wood-cut by a black line, which admits cold air, and prevents the plate from ever being too hot for the sugar; this chink has a register to regulate the air admitted.

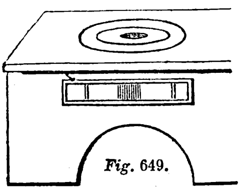

Fig. 649.

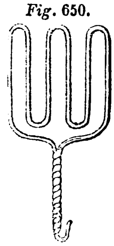
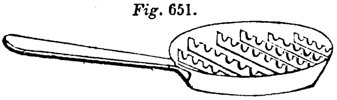
4573. *A small apparatus for broiling* or holding anything over the fire to warm is sold in the streets of London for a penny; and is interesting from its extreme simplicity. It consists merely of a piece of iron, which has been cut an eighth of an inch square, bent as in *fig.* 650, and having a handle, formed by binding the two ends with some wire or a strip of tin. There are no feet; but its use is to put between the bars of a grate, when the fire is low, or over the fire. The size of the gridiron part is usually about nine inches long, and six or seven wide. Some are made with more and closer bars.

Fig. 650.



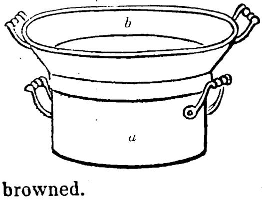
4574. *An apparatus called a new kind of gridiron* has lately appeared in the shops, and we give it, because it may have its use on particular occasions, without pronouncing upon its general utility. *Fig.* 651 represents this apparatus, which resembles a frying-pan in shape; but it has cross partitions, on which the meat is laid. It is evident that the broiling is effected by the heat radiated from the iron. By this means the fat is prevented from falling into the fire, and causing the flare so troublesome in ordinary broiling. A hint may be taken from this for improving the traveller's frying-pan, or, rather, for converting it into a gridiron.

Fig. 651.



4575. *Perpendicular gridirons*, made of a strong kind of wire, and double, so as to enclose the meat to be dressed, are sometimes convenient; they hang before the fire, and the meat is turned merely by turning the implement; but though this is strongly recommended by Dr. Kitchener, on account of the smoke being quite avoided, the meat is rather roasted than broiled. They may, however, also be used horizontally, without the dripping pan, over the fire, and the turning is then performed with the same facility.

Fig. 652.



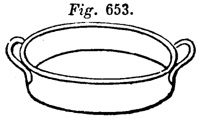
4576. *Braising pans*, *fig.* 652, are copper vessels much used in French cookery for performing the operation termed braising. The lower vessel, which holds the meat, is covered by another, *a*, that fits quite close, so that there can be no evaporation; and it serves also, by means of a raised rim, to hold burning charcoal, by which the meat is browned.

Sect. IV.—Apparatus for Frying.

4577. The common frying-pan is too well known to require anything being said about it. It affords the readiest mode of dressing meat on many occasions; a few sticks, and a stone or brick or two, being all that the traveller or soldier requires or can procure for the operation. The frying-pan is made of wrought iron, and is frequently tinned inside, but that is not necessary, if it be well cleaned out. Count Rumford shows that by covering the frying-pan with a deep earthen-ware bowl, it may be converted into a vessel for cooking partly by steam.

4578. *The Sauté-pan, fig.* 653, is a shallow copper vessel with two handles, used in French cookery to *sauter*, which is a term of art nearly but not quite analogous to *frying;* for in this operation the fillets of meat are frequently turned or tossed over with great celerity as soon as they are affected by the heat; hence the term *sauter*, "to jump;" it is a mode of frying with very great nicety. The name is corrupted by English cooks into *sooty-pan.* See explanation of the terms in French cookery, Book XIV., Chap. I.

Fig. 653.

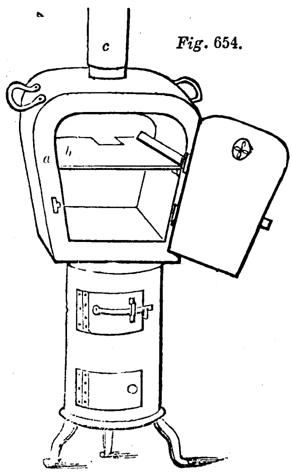


SECT. V.—APPARATUS FOR BAKING.

4579. For various kinds of ovens, we refer the reader to the description of bakers' ovens under "Baking Bread," Book IX., Chap. III., Sect. IX. Some other contrivances of this kind will here be noticed. We have mentioned that ovens are now very generally attached to kitchen ranges; some of these perform very well, while others have been found almost useless. They seldom answer well if the heat comes to one side only from the fire; to be complete, the heat should be made to pass quite round the oven, and also over the top. When a separate fire is made below the oven, there is danger lest the heat on the bottom should be too great; in that case, it is generally necessary to put a tile or a dish with some sand on the bottom, to prevent the bread or meat from being burned.

4580. *Portable ovens* are occasionally very useful. *Fig.* 654 represents a portable oven of sheet iron, of a convenient form. The oven itself is placed upon a sheet iron German stove; and the flame and smoke, after circulating round the oven between the double sides, *a* and *b*, pass off into the vertical tube, *c*. This oven may also be used, but not so well, without the German stove, by placing it on the top of the kitchen grate.

Fig. 654.



4581. *Green's portable oven for baking meat or bread* is represented in *fig.* 655. A cast iron pan, *a*, with a cover, but without a bottom, is placed upon a cast iron shelf, *b c*, in an oven of tin like the American (p. 817), having a plate of tin slanting upward towards the back from the edge of the bottom, and the top of the oven slanting downward as usual. The meat or bread is put into the pan, *a*, and the whole is placed on a stand before a clear fire. The reflection of the heat upward from the slanting bottom, and downward from the top, is so considerable, that it penetrates through the cast iron to the meat sufficient to cook it thoroughly. It is essential to observe that the whole inside of the Dutch oven and of this must be kept perfectly bright, but that the cast iron pan of this oven, and shelf on which it stands, must be japanned black, in order that they may absorb the heat; if these were also of bright tin, the same effect would not be produced. The shelf is placed upon small brackets on the sides; and in order to take out the pan, *a*, with the meat, to examine if it be done, a ring, *d*, with a handle, *e*, is put below the cast iron shelf, by which the whole can be lifted up and put back again, if more time be required. For bread, a tin pan receives the dough, and is placed on the shelf and covered by the pan, *a*. It is said that this oven will bake rolls for breakfast; a seven pound loaf in the forenoon; a pie, meat, or fowl for dinner; cakes for tea; and anything else for supper. It is durable, and not liable to get out of order; it may be particularly useful to emigrants.

Fig. 655.

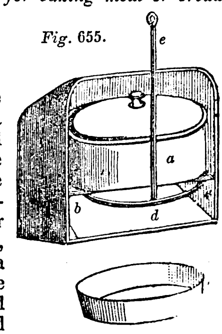


Fig. 656.

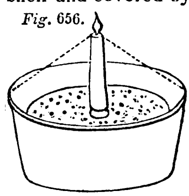

4582. *A potato pasty pan, fig.* 656, has been lately invented. A tin vessel, slightly conical, has a cover pierced with holes, which stops an inch and a half below the top; the meat, properly seasoned, is put into the pan beneath this cover. In the centre of the cover is an aperture, into which is screwed a short tube, that can be closed by a stopper which fits loosely. Potatoes mashed with milk in the usual way are heaped up on the cover and round the tube as high as the dotted line, and the whole is put into an oven. The potatoes may serve as a crust to a pie, no other being necessary, and the juice and flavour of the meat will ascend partly through the holes and enrich the potatoes.

SECT. VI.—APPARATUS FOR BOILING.

4583. Vessels for boiling food in are to be considered with reference to the kind of food required to be cooked, its quantity, the fuel employed, the materials of the vessels, and their durability and price. The largest kind are termed *boilers* and *kettles ;* the smaller *sauce-pans ;* those in Britain are always made of metal. *Boilers on a large scale* for public establishments are sometimes made of copper, and set in brick-work like washing coppers ; and occasionally they are made square, which form has some advantages in the setting with brick-work, and the economy of fuel. Count Rumford advocated the propriety of having all boilers to fit into closed fire-places ; but this demands that kitchens should be constructed purposely. With respect to the properties of the several materials of which kitchen utensils are made, we refer the reader to Book V., Chap. V., "Materials of Furniture."

4584. *Boilers so small as to be portable* were formerly always suspended over the fire, or made to stand upon feet, or upon a trivet ; but the waste of fuel by this mode is immense. *Fig.* 657 represents a pot, or kettle, of cast iron made at Carron, and generally used in the north of Scotland for making broth, but in London used chiefly for boiling pitch. Where turf is the fuel, it either stands upon the ground, having the burning fuel heaped up around it, or is hung up by a chain and hooks that clasp into the ears of the pot ; the pots are not tinned, yet are perfectly clean and wholesome. In some places the pot has an iron lid, by which it forms an oven ; the lid is put on the ground, with the meat, bread, or pie on it ; this is covered by the pot inverted, and live coals of turf heaped over it.

4585. *Kitchen boilers, or kettles, fig.* 658, are large vessels of tin, copper, or cast iron for boiling joints of meat, soup, or only water ; they may be round, but are usually oval, with two handles.

Fig. 657.

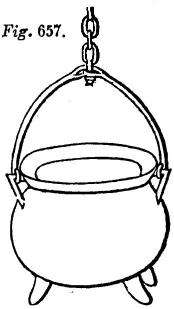

Fig. 658.

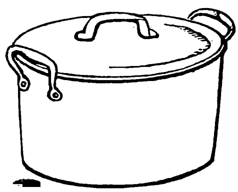

Fig. 659.

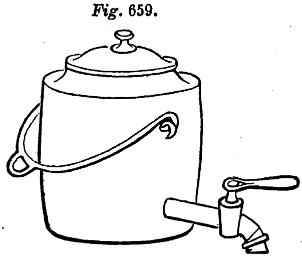
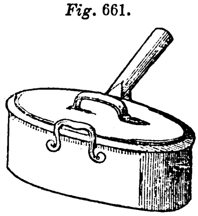


4586. *Tea boilers, fig.* 659, are made of cast iron, and hold two or three gallons of water wanted for tea ; they are detached vessels, and, being boiled over the fire in the range, are kept hot upon the hob ; they have a cock to draw off the water.

4587. *Fish kettles, fig.* 660, are of an oblong form, having two handles, and have a

Fig. 660.

Fig. 661.

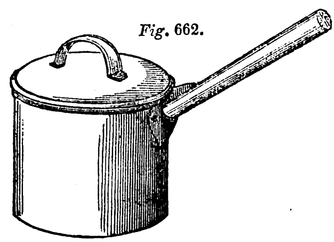


moveable bottom pierced full of holes, on which the fish is laid, and on which it may be raised out of the water by means of two long handles, to prevent its being liable to be broken, as it would be when cooked in a common sauce-pan. A smaller kind, *fig*. 661, is called a *mackerel kettle.*

4588. *Sauce-pans* are the smaller round vessels for boiling, made with a single handle. In Britain these are made of various materials, copper, sheet iron, cast iron, and tin plate ; the most common are those of tin plate, that is, sheet iron tinned. In treating of the materials of furniture, Book V., we explained, under "Iron" and "Tin," the nature of tin plate ; but it is necessary here to repeat that many persons are in error respecting this substance. From nothing being visible on the surface but the metal tin, the iron being entirely covered, many persons imagine that these tin sauce-pans are made wholly of the metal tin, and not of iron; in fact, that those which are usually said to be of *block* tin are made of tin alone; but the truth is, that both common and block tin are merely iron plate coated on both sides with tin. The use of thus coating sheets of thin iron with tin is this: iron alone soon rusts when exposed to the air and damp; but as tin is, fortunately, a metal that does not rust in the air, the iron is plated with it to defend it. Any one may easily convince himself of the nature of tin plate by scraping off with a knife the tin from a piece of a sauce-pan; it will be found that the tin itself is soft, and can be easily cut or scratched, which is not the case with iron; and if the spot so scraped be exposed to damp air, it will soon become covered with rust, while the part that remains tinned will not; also, if the edge of a fresh-cut piece of tin plate be examined with a magnifier, the difference between the iron in the centre and the tin on each side will be easily recognised. What is usually called block tin is merely a superior kind of tin plate. This useful information being gained, which, though familiar to many, is far from being so to all, the precautions necessary for preserving tin sauce-pans will be more easily comprehended; for whatever wears off the tin from the iron exposes the latter to rust, and this in a short time corrodes, or, as it is called, *eats* the iron into holes; whereas, if the tin be protected, the sauce-pan may last for a very long time. (See farther observations on tin plate under "Materials of Furniture," Book V.) One of the principal causes of the destruction of tin sauce-pans is what is termed *burning* in the inside, an effect which is seldom understood. This so-called burning is caused by suffering the sauce-pan to remain on the fire with too little liquid, or permitting some substance to attach itself to the bottom through neglect in stirring, in consequence of which the metal becomes much more heated in that part, and the tin itself is fused and separated from the iron; this may be perceived to have been the case by the ridges and drops of pure tin that will then be seen collected on the inside. The iron, being thus exposed, appears black, and soon oxidates or rusts, which explains the incorrect expression *burned*. There is no remedy for this accident or neglect after it has occurred, since the tin cannot be put on again, and a sauce-pan so treated must, of course, very soon wear out. Tin sauce-pans likewise require to be dried with great care when they are put away, as every good cook knows; because although, as we stated, tin itself is not liable to rust, yet, in the manufacture of tin plate, the iron is seldom or ever so completely covered but that there are little places, even so small as a pin's point, that have escaped the coating, and in these minute spots the iron is liable to be attacked by rust.

From this description of the tin plate of which sauce-pans are made, it will readily suggest itself to every one that it must be improper to scour them often with sand, or any coarse gritty powder, since this must necessarily cover the tin with scratches, and soon wear it off. The tin should be cleaned bright when necessary, by something soft, as soft Bath brick; but even this as seldom as possible: they should be washed out immediately after being used, and the grease removed by hot water, and sometimes, perhaps, by the use of a little soda or potash; after which they should be thoroughly wiped and dried, and kept in a dry place. The French cooks wash out their stew-pans with a lye made with wood ashes, which contains some of the alkali potash: this they call *lessieve*.

Fig. 662.



The handles of common tin sauce-pans, *fig.* 662, are made of a piece of tin rolled round into a conical form; but this, being fixed on with soft solder, is apt to come off if the flame is suffered to come to it. Sauce-pans are made of various sizes, from holding half a pint to several quarts. When they are very large, they have generally an additional handle, such as those represented in the fish kettle, *fig.* 662.

The covers or lids must not be made to project beyond the sauce-pan itself, though this might seem to form a protection against anything getting in; but it occasions an inconvenience, that it draws the smoke into the vessel. The lid and sauce-pan should be precisely of the same diameter. The covers are seldom made double; but it is very advantageous for them to be so, on account of their confining the heat much better. Count Rumford recommended that they should be of a conical form, as *a*, *fig.* 663, with a space for confined air between the horizontal and inclined plate, and a tube through the centre to let out the steam, to which a stopple and chain must be adapted, the handle being placed as in the cut *a*; a better form might be as *b*. The suggestion is excellent, but it does not appear to be adopted. One of the best covers for confining heat, where superior neatness is not a primary object, is wood, or wood lined with tin, *fig.* 664, as being a non-conductor; these are often used where cast iron kettles are employed.

Fig. 663.

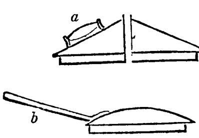


Fig. 664.

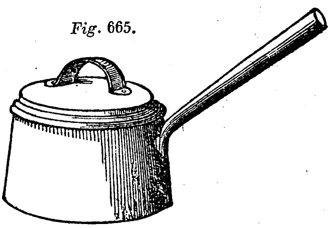
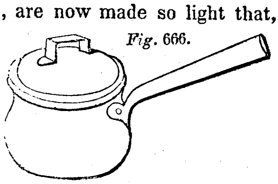
4589. *Copper sauce-pans* are generally of the form of *fig.* 665. These are much more durable than tin plate, but likewise much more expensive at first. It is essential that they should be kept well tinned in the inside. Sauce-pans are likewise made of the same form of *sheet* iron, japanned black on the outside, and tinned within. These are much stronger than those of tin plate, but do not last so long as those of copper. Some cooks have a great prejudice against them, and pretend that iron sauce-pans will turn black whatever is cooked in them ; but this opinion is evidently erroneous, provided the cast iron is kept tinned, or even well cleaned ; and, as we have shown, the iron is not at all prejudicial to health, should the tin wear off. The difference between the two appears chiefly to be matter of calculation as to expense ; for the copper will not only last longer, but will sell for something after it is worn out, which the iron will not. It is said, also, that iron sauce-pans require tinning oftener than copper.

Fig. 665.



Cast iron sauce-pans, fig. 666, though heavier than tin, are now made so light that, when small, they are nearly as manageable, and with care will last a lifetime. These are coming very generally into use ; they are usually tinned inside, but if not, or should the tinning wear off, it is of little consequence, as they are perfectly wholesome without it, and are very little liable to rust. The handles are made of a piece of wrought iron rolled up hollow, and riveted on ; as also the handle of the lid. They are often fitted up with a steamer on the top. The outside is japanned black. It is to be remembered, that though they are very strong if carefully handled, yet they are brittle, and will crack if cold water be thrown upon them when they are hot.

Fig. 666.



Count Rumford suggested the expediency of lining small copper sauce-pans throughout with a thin sheet of another metal, and observes that the cost would not be great, even if that lining was made of silver, which would form a cheap and elegant utensil.

4590. *Lining the inside of sauce-pans with silver* is now effected at a cheap rate by the electrotype process. This will have one advantage, that the silver will not melt like the tin, and, consequently, the accident to the sauce-pan, called " burning," will be avoided ; but it has been shown that tin is sufficiently wholesome ; and it is evident that silvering, being very expensive, is not likely to be used generally.

Attempts had been made in Germany, about forty years ago, to improve cooking vessels made of cast iron, by covering the inside with a *white enamel*, or *glaze*, but this was liable to the objection that the glaze was apt to crack and fly off, from the unequal expansion of it and the iron. This practice has lately been imitated in this country, and, we believe, with better success. Sauce-pans and frying-pans with the inside enamelled appear now commonly in the shops ; but before recommending them, we must wait for the experience of cooks ; and we do not know whether lead is employed in the glaze.

4591. *In ancient times*, the arts of rolling out copper into sheets, and that of tinning as practised at present, were not known ; and as copper cannot be cast, tin or zinc were added to it to render it fusible, which constitutes bell-metal and brass. Sauce-pans were then made of the latter alloy, which is less oxidable than copper alone ; vessels of brass formed the great ornaments of old kitchens, and from their rich colour were favourite objects in the pictures of the Dutch painters. Brass is at present little used in our kitchens, except for *skillets*, small sauce-pans used for boiling milk and starch, being, it is said, less apt to burn to than copper.

4592. *Strong iron boilers, called digesters*, are often used in making soups. They have a lid that screws down tight, so as to confine all the steam ; and by this means the water may be heated several degrees above the boiling point. These boilers were first invented by Papin ; if they are sufficiently strong, the water may be heated to a very high degree, but as there is considerable danger of their bursting with an explosion, if the force of the steam should at last exceed the strength of the vessel, a safety-valve is now placed in the lid, by which accidents of this kind are avoided ; likewise, the heat of the steam can be regulated by putting more or less on the valve. By means of these, not only can meat be entirely dissolved, but even bones, if ground to powder, may have the whole of the gelatin extracted, leaving the earthy part. However, if they are unskilfully managed, the earthy salts of the bones are apt to get mixed with the liquor, and make it both disagreeable and unwholesome. They are now seldom used for this purpose, but may be advantageously employed in making economical soups.

4593. Every person conversant with the most ordinary culinary operations has noticed how often liquids, especially milk, are spoiled by what is called *burning to.* To prevent this evil, Count Rumford recommended double bottoms to all boilers and sauce-pans used in cooking. 'The heat, he observes, is so much obstructed in its passage through a thin sheet of air, which, notwithstanding all the care that may be taken to bring the two bottoms into contact, will still remain between them, that the upper bottom has not time to give its heat as it receives it to the fluid in the boiler, and, consequently, it never acquires a degree of heat sufficient for burning anything that may be upon it.

4594. *The effect of burning to is effectually prevented by the apparatus called by the French "Bain Marie,"* which will be shown among the vessels for stewing. We must observe that this "burning to" is not the same accident as that of *burning*, as it is called, of the sauce-pans mentioned above. The first is the burning of the food, the latter the injury to the sauce-pan itself.

4595. *Preserving-pans* are for boiling sugar and sirups; they are usually of copper, *fig.* 667, and require a well-regulated heat, for which the charcoal stoves and hot plates are convenient. Steam has been employed for preserving-pans; and it has this advantage, that the sugar is never exposed to a heat above 212°, and, therefore, can never be

Fig. 667.

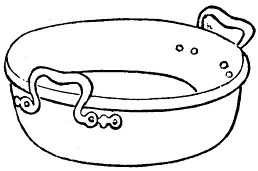


Fig. 668.

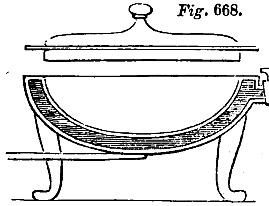

burned. For this purpose, the bottom must be double, as in *fig.* 668, and the steam is admitted between by a pipe, while the condensed water runs off by a small pipe from the bottom. They may be made to be detached from the tube when required.

SECT. VII.—APPARATUS FOR STEWING.

4596. Stewing requiring a more gentle and equal heat than boiling, cannot be effected so well over an open coal fire. The only usual method in this country formerly was by means of *stewing hearths*, or *stewing stoves*, which are still employed, and almost universally by French cooks.

4597. *Stewing stoves* are small pits, *a*, *a*, *a*, *fig.* 669, formed in a mass of brick-work, *b*, *c*. These pits are from six to twelve inches square, and four inches or more in depth: they have an iron grate at the bottom, and below that is the ash-pit supplied with air by an aperture in front. Charcoal is always burned in them, and as this gives no smoke, no flue is made. The stew-pans are placed over the fire in these pits on tripods or bars of iron. The front is best made of neat brick-work, but some prefer making this of iron, which lasts longer, and is less apt to get out of order. The top also, which is sometimes covered with paving tiles, is best made of cast iron. The pits themselves ought to be lined with fire bricks, with an iron rim around them, or an inside lining, or a box made of cast iron. The aperture in front, *d*, *e*, may be either left open, or partly filled up with a drawer, *f*, to hold charcoal, and another smaller one of iron, *g*, to receive the ashes, a space, *h*, being still left open for the draught. This kind of stewing stove is found very convenient, and may be fitted up in any place at a small expense. The only objection that appears to it is, that it produces a great deal of unwholesome gas by the combustion of the charcoal, which is extremely injurious to the health of the cooks. Instead of the situation at the side of the chimney, some cooks prefer having the stewing stoves placed on the window side of the kitchen, for the benefit of a full light. These stewing stoves are less employed in London kitchens on a large scale than they were formerly, being, in a great measure, superseded by the hot plates to be described afterward; but the best cooks consider them as superior to the latter, the heat being more mild and more easily regulated; accordingly, sometimes some of each kind are placed in the kitchen. To carry off the vapours of the charcoal, it would not be difficult, in many situations, to have a hood constructed over the stoves with a flue at the top leading into a fire-flue, or through the wall, to the outside of the kitchen.

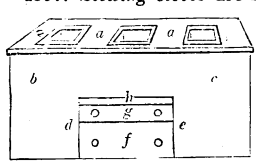

Fig. 669.

4598. A very ingenious method of employing common coal for stewing stoves, instead of the charcoal in common use, was invented by Count Rumford, and executed at Munich, and also at the Royal Institution, in 1800; a great many of them were likewise made in London by various tradesmen; but as they are not manufactured at present, and as those put up in the Royal Institution are no longer to be seen there, we do not think this is the place to enter upon their description; those who are desirous of learning something about these culinary inventions, may consult the count's "Essays."

4599. *The vessels for stewing in* differ from those used for boiling. *The stew-pan, fig.*

670, is usually made of copper, instead of being of tin like the sauce-pan, and they are less deep. The handles of the cover are placed as in the wood-cut.

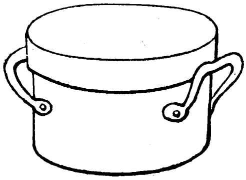
Fig. 670.

The advice to keep copper stew-pans well tinned on the inside cannot be given too often, since it is well known that fatal accidents have happened through neglect of this precaution. The tinning should extend about an inch and a half from the top downward on the outside.

4600. *Stew-pans are likewise made of cast iron;* these answer for stewing as well as those of copper, and are much cheaper at first, though they do not look so handsome in the kitchen as copper kept bright. Many cooks dislike them, and the same observations which we made on iron sauce-pans apply to these. A certain thickness of metal appears to be necessary for stew-pans; for in a common tin sauce-pan, the cooks say it is very difficult to prevent *burning to.* Stew-pans are made a little rounded at the edges of the bottoms, and not angular like tin sauce-pans, and therefore they are thus more easily cleaned out.

4601. *Stock pots* are strong kitchen boilers for stewing meat into gravies and broths in French cookery, *fig.* 671. They are generally made of copper, but have lately been manufactured of cast iron rendered malleable; these are blacked outside, well tinned inside, and answer the same purpose as copper vessels, with the advantages of greater cheapness and wholesomeness. They may be purchased of various sizes, price from 14*s.* to 36*s.*

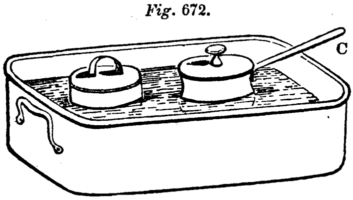
Fig. 671.



4602. *On the Continent earthen-ware vessels are preferred* for stewing, not only on account of their low prices, but because, being worse conductors of heat than metals, they confine it better, and are less apt to burn to. Count Rumford endeavoured to improve cooking vessels of this kind, and several specimens were deposited at the Royal Institution, but, from various causes, they have never found their way into common use; and we are at present nearly destitute of earthen-ware vessels of the proper quality for stewing, and of such price as would render them attainable by the poorer classes.

4603. *The Bain Marie, or water bath* (in Latin, *balneum mariæ*), is an apparatus, *fig.* 672, extensively employed in nice culinary operations, particularly by French cooks, and now generally by English cooks, who have corrupted the name, oddly enough, into *Bambury.* It is made of copper, kept nearly full of water, and heated over a stove, or by steam; it is thus described by the renowned M. Ude: "The bain marie is a flat vessel containing boiling water; you put all your stew-pans into the water, and keep that water always very hot, but it must not boil. The effect of this is to keep every dish warm without altering either the quantity or quality. When I had the honour of serving a nobleman in this country, who kept a very extensive hunting establishment, and the hour of dinner was consequently uncertain, I was in the habit of using the *bain marie* as a certain means of preserving the flavour of all my dishes. If you keep your sauce, or broth, or soup by the fireside, the soup reduces and becomes too strong, and the sauce thickens as well as reduces." This is the best method of warming up soups and similar things.

Fig. 672.



4604. *Hot plates* are a modern improvement used for stewing and boiling. The hot plate is merely a large plate of cast iron, *a, b, fig.* 673, laid hollow on a raised hearth, and having a closed fire burning under it, and traversing in a serpentine manner, by which the plate is heated excessively, and, indeed, sometimes almost made red hot. Upon this plate the various stew-pans, sauce-pans, &c., are set, and the heat is sufficient to keep them stewing or boiling, a method which is found very convenient, and saving a great deal of trouble. With them coal may be used, and the smoke is carried off by a flue. They have, however, the inconvenience of heating the kitchen too much, except some contrivance is resorted to for carrying off the hot air; but they have not the evil produced by stewing stoves of creating the unwholesome charcoal gas. With respect to the heat, it must be observed that it is undoubtedly injurious to health, yet cooks do not, in general, complain of this so much as we might suppose; they say it is hurtful at first, but that in time they get seasoned to it! To insist upon the bad effect of such

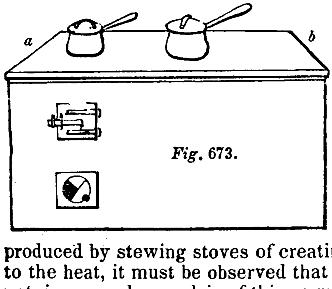


Fig. 673.

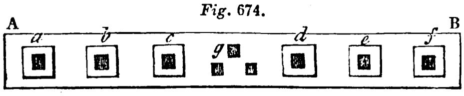
heat, probably appears to them like a slur upon their profession, as they imagine cooking and great heat to be inseparable.

Jeakes's broiling stove may be made to form a part of the hot plate. In the kitchen of the City Club, several of these broiling stoves, *a, b, c, d, e, f, fig.* 674, form part of a very long hot plate, A B, extending across one side of the kitchen, and having these charcoal stewing stoves as part of the arrangement, which serves for broiling, boiling, and stewing, with great convenience.

Fig. 674.



The hot plate is best placed in a recess like a large chimney, with a flue to carry off the heated air, as in the kitchen of the Merchant Tailors' Hall, where advantage has been taken of two large ancient chimneys. This convenience cannot be always obtained, except in the case of a new kitchen, where the architect may provide for it. In some places a hood might be brought over the hot plate with a proper contrivance above to carry out the hot air.

SECT. VIII.—COOKING BY STEAM.

4605. The application of steam to the art of cooking is a modern invention; and as this great agent has been found extremely convenient in other arts, it is here particularly so. It has been pretty generally practised in this country with more or less success for nearly half a century, but of late there have been great improvements in the modes of using it and in the apparatus.

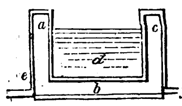
4606. *Cooking by steam is, indeed, one of the greatest advances which have been lately made in the culinary art.* Not only can steam be conveyed to any part of the kitchen with the greatest facility, so as to be used where no fire could be introduced, and thus economy and cleanliness are obtained, but this mode of cooking has several other advantages. Steam kitchens, as they were called, have been sometimes fitted with very complicated machinery, which is expensive, and too much has often been attempted. There is no doubt, by ingenious contrivances, it would be easy to show what steam, as well as gas, is capable of doing; but what we particularly wish is, that cooking should be performed either *better* or *cheaper* than by the ordinary methods. Experiments showing merely what it is possible to effect are, however, always valuable, and ordinary cooks have not yet learned to make all the use of steam that is possible, even by very simple and easy methods; nor can this be expected, except they were better acquainted with philosophical principles. It is only from those who possess this knowledge that improvements in the use of steam can proceed; yet the few leading facts that are essential to be known are far from being above the attainment of those who have most occasion for them, and we shall endeavour to render them easy to be understood.

4607. *We here recommend the reader who wishes to understand steam* to peruse what we have said in Chap. I., Book II., on the subject of the boiling of water, and to consider carefully the description of the manner in which water is converted into steam. But to save a great deal of trouble, perhaps it will be better here to enumerate the principal circumstances respecting steam, at the risk of some complaints of repetition.

Water, then, always becomes converted into an elastic gas called steam, when it is heated to 212° under the ordinary pressure of the atmosphere. Steam itself is perfectly transparent and invisible like common air, and will remain so as long as the heat of 212° is kept up; but no sooner does it come into contact with any body colder than itself than it parts with some of its heat, and can no longer remain in the state of steam, but returns to that of water, which, however, will be at first so hot as to be nearly boiling. This return of steam to its former condition is termed its *condensation*, and there are some remarkable circumstances connected with it. Steam, we have said, is an elastic substance like air, and may be considered as in fact a kind of air or aqueous gas, which requires to be kept up to 212° to be permanent. Now, as a vessel which is called empty is still full of air, it is impossible to put another kind of air into the same vessel except the first be taken out; in like manner, steam cannot be put into a vessel except the common air be extracted. Steam is lighter than common air, and therefore, if introduced into a vessel filled with air, it will occupy the upper part of the vessel, if there are openings by which the common air can get away.

To illustrate this important fact, suppose it was required to put steam into the space *a b c*, *fig.* 675, between two vessels of different sizes, in order to boil the water in the inner one. It would be impossible to cause the steam to enter at *e* except openings are left at *f*, by which the common air could be driven out; but by degrees the whole of the air would thus escape by the pressure of the steam, which would then entirely occupy the space *a b c*. It is in this manner that water is made to boil in vessels placed upon wooden tables at a distance from the fire in the kitchens of some of the London club-houses. Another important fact with respect to steam is, that, if a jet of cold water be suddenly let into a ves-

Fig. 675.



sel thus filled with steam, the latter will be instantly condensed into water, which will occupy only a very small space compared with what it did as steam. Now as the common air had been driven out at first, when this condensation takes place there is neither air nor steam in the space so occupied, which will now be absolutely empty, or, as it is termed, a *vacuum*. This vacuum would have to resist an immense pressure from the surrounding atmosphere; and if the sides of the vessel were not very strong they would give way; but steam itself is able to resist this pressure as well as the air.

From this it must be understood that steam may be conveyed in pipes to any distance, provided the heat of 212° can be sustained, but no farther; and that, as some heat must escape in its course through a length of pipe, it is proper, in conveying it, to cover the pipes with the worst conductors that can be procured, to prevent its condensation.

It is obvious, therefore, that as long as steam can be kept from condensing, it possesses the temperature of 212°, and, of course, has heat enough to effect whatever process of cookery boiling water can.

4608. *Steam is applied in cooking in a great variety of ways.* The food is put into vessels kept full of steam, in which they are subjected to the same degree of heat exactly as in boiling water; or water itself is made to boil by means of steam, either by bringing it by a pipe into the water, or, which is much better, by causing the steam to surround a vessel full of water, as is shown above. One of the simplest methods of employing steam is the following:

4609. *Sauce-pans and boilers are made with another vessel called a steamer* on the top. The bottom of the steamer is perforated with numerous holes to admit of the entrance of the steam from the water boiled in the sauce-pan beneath. This arrangement is exceedingly convenient and economical, since one article of food may be boiled in the sauce-pan, and another may be cooked by the steam in the upper vessel, without any additional expense of fire. Vegetables are often so prepared, and, if it is found useful, any number of steamers may be placed over each other on the same sauce-pan, each steamer having a perforated bottom. *a*, *fig*. 676, represents a sauce-pan with a steamer of tin; *b*, *fig*. 677, is a cast-iron sauce-pan with a tin steamer.

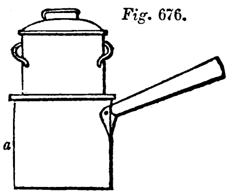


Fig. 676.

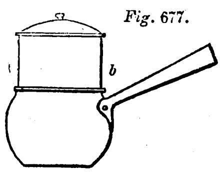

Fig. 677.

Fig. 678 represents one of Count Rumford's kitchen boilers with its steamer, of which thousands were formerly made in London, and which were put up in the Royal Institution, and are described in his "Essays." *a* is a section of the boiler with its steam rim set in brick-work, and heated by its own little fire; *b* is the steamer placed over the sides, fitting into the rim of the boiler. The sides of this steamer are of double tin, the better to confine the heat, the outside being cylindrical, but the inside slightly conical. The conical cover fits into the steam rim of the steamer. This steam apparatus is very perfect for the purpose for which it is intended, but is now no longer made.

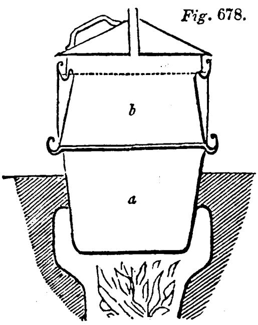

Fig. 678.

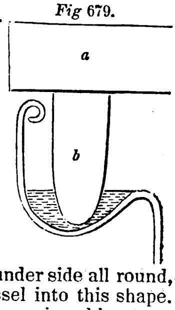
Steam was much employed by Count Rumford for cooking for public establishments on a great scale with a view to economy; and we may here describe an ingenious contrivance of his for preventing the steam from escaping from the large boxes of wood lined with tin in which potatoes and other things were cooked. *a*, *fig*. 679, is a portion of the wooden cover of these steam vessels, and *b* is a projecting tongue on the under side all round, that shuts down into a cavity caused by bending the tin of the vessel into this shape. The consequence of this is, that this cavity is always full of water occasioned by some of the steam condensing; and as the tongue *b* comes down into this water, no steam can escape out of the vessel without first displacing this water, which steam of the ordinary strength cannot do. Vessels, therefore, made with these *steam rims* are steam-tight, that is, do not throw out any steam into the apartment. It must be very easily seen how useful such a steam rim would be in every brewing and washing copper, as well as vessels for cooking by steam; yet this excellent contrivance appears to be forgotten already.

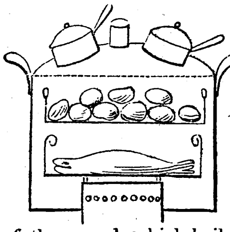
Fig 679.



Although direct steam may be employed very advantageously for cooking meat, fish and vegetables on many occasions, yet we have the authority of some of the best cooks, such as those at Buckingham Palace, the Albion Tavern, City Club, &c., for saying that neither meat nor fish is so well cooked in steam as in boiling water. The juices of the meat are too much drawn out, and fish is rendered less firm than by boiling: hams form an exception. Nevertheless, although this may be admitted to be the fact, still the difference is not so great that we should object to the use of steam when economy or great convenience recommends it. In the case of steaming joints of meat, although much of the rich gravy is forced out of the meat, yet it is all preserved in the dish below, and may be returned upon the meat, or served up with it.

Fig. 680 represents the section of a kettle made by Mr. Evans, Fish-street Hill, in which fish, potatoes, and their sauces may be cooked by the steam of a boiler at the side of the kitchen range. This kettle fits on the oval opening on the top of the range boiler at A, the dots showing the holes which admit of the steam. In this kettle is put an oval plate, on which the fish is laid; and over that is a similar plate for the potatoes, both of which are lifted out by bent wires for handles. In the lid of the kettle are openings, in which are fitted small tin dishes with covers for melted butter, sauces, &c. It is evident that this principle may be modified in numerous ways, of which this specimen may serve sufficiently as an example.

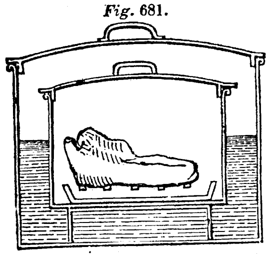
Fig. 680.



4610. *Meat and fish may be boiled in water* by means of steam with great advantage, by the method which is practised at the Albion Tavern, London, and other places, and which has been already described in *fig.* 675, namely, by admitting the steam between the double sides and bottom of the vessel, which boils the water in the inner one; and it is really beautiful to see a great number of tin vessels constructed in that manner boiling various kinds of meat and vegetables, and standing in a line on a long wooden table close to the wall, *at a distance from the fire*, the water being kept boiling by means of a pipe full of steam from the range boiler.

4611. *Meat and vegetables may be cooked merely by their own juices, without the addition of any steam or water.* To effect this, two vessels must be provided, *fig.* 681; the larger one to hold water, and the inner one, of course less, to hold the meat to be cooked. Both must have covers of the ordinary kind. The inner one must be supported upon a trivet, to keep it a few inches from the bottom of the outer vessel. Water must be put into the outer vessel so as to rise a few inches above the bottom of the inner one. The whole is to be placed over a fire or stove, or on a hot plate to boil. When the water in the outer vessel boils, the heat will be communicated to the meat; but the heat in the inner vessel will never be quite equal to 212°, that of boiling water; consequently, the meat will take one third, or perhaps one half, more time to cook than if it were in steam or water; but, on account of the slowness of the process, it will be the more tender. A shallow tin pan, with a few bars across the top, should be put in for the meat to lie on, and to collect the rich gravy that runs from it. Eggs can never be rendered hard in this apparatus; though kept in half an hour, the white becomes only of the consistence of a jelly. It is evident that this is really a balneum mariæ with a cover.

Fig. 681.



4612. *An apparatus for cooking potatoes* without water has been some time sold in the shops, *fig.* 682. This consists of a sauce-pan of sheet iron, to stand the fire on which it is put. Within is a false perforated bottom, to hang in an inch from the bottom of the pan. On this upper bottom the potatoes are laid, and the heat and vapour raised from themselves are sufficient to cook them when the cover is put on. It is evident that if a very little water be put in, the potatoes will be dressed in the steam. This apparatus costs about six shillings, and is found to answer perfectly.

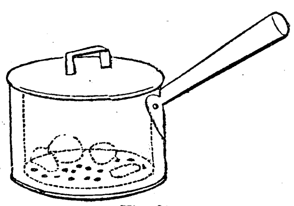


Fig. 682.

4613. *Fig.* 683, opposite, represents the arrangement of a steam apparatus, placed in a recess in the wall in the kitchen of the City Club-house, London. *a* and *c* are vessels containing water boiled by steam by means of the sides and bottom being double, the steam being introduced between them, as described above. *b* is a larger receptacle kept full of steam; in the cover are four circular apertures, in which smaller vessels are placed, having the bottom and sides perforated with numerous holes to admit the steam to the potatoes dressed in them. *d* is another vessel kept full of steam only, for cooking hams. *e* is a section of the vessels *a* and *c*; *f* is one of the small circular vessels in *b* with the holes. The several vessels are supplied with steam from a large steam boiler placed in the scullery, which likewise furnishes steam to various hot closets. It is more convenient to have the boiling and steaming vessels distinct, than to have one placed upon the other, as is sometimes the case, an arrangement only desirable when there is little room.

4614. *g*, *fig.* 683, is a large fish-kettle in the kitchen of the Merchant Tailors' Hall, with double bottom and sides, for boiling several turbots at once in water heated by steam between the sides; *h* is a stand, with two or more pierced shelves, to place the fish upon in the water.

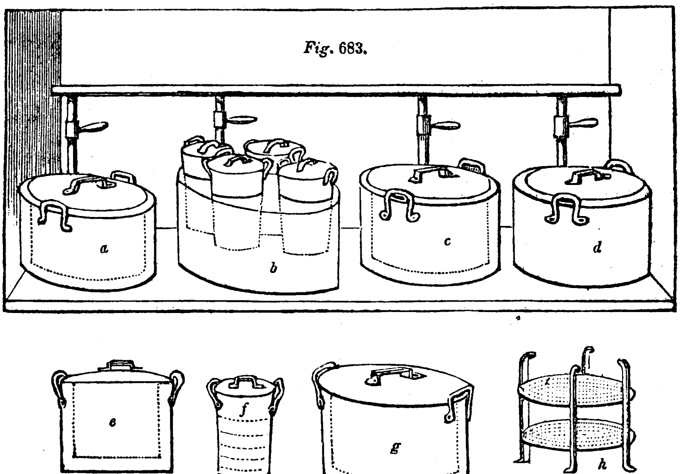

Fig. 683.

4615. *Fig.* 684 represents a *Bain Marie*, in which the water is heated by steam by means of a double bottom having the steam between. It is made of copper, and placed upon brick-work. The same method may be employed with advantage when it is required to heat any liquid without the danger of *burning to*.

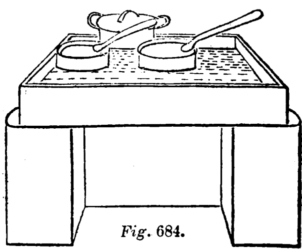

Fig. 684.

4616. The following observations on steam we probably would not have been induced to make, had we not observed, in the description of a cooking apparatus by a London manufacturer, a proof that the subject of steam is not so generally understood as it ought to be by this class of persons. The inventor of this apparatus states that the novelty of his invention consists in his employing what he terms *dry steam*, which, he says, is "*steam not in a pure state, or not completely saturated with water.*" He adds that *his* steam is invisible in the atmosphere, and of a superior kind, &c. It is proper here to state, that such an erroneous view, and such a confusion of ideas, should be corrected, since we believe these are not confined to the individual in question. It appears that some persons have a notion that there are two states of steam, dry and moist. This mistake arises from confounding the visible aqueous vapour which we see issuing from the spout of a tea-kettle with actual steam, and calling this *moist* steam. We have stated above that water rendered perfectly gaseous by boiling is, in reality, always dry, transparent, and invisible; when this steam loses part of its heat of 212° by contact with a colder body, or by coming into the atmosphere, it is condensed into a visible vapour, which, although, in common language, still called steam, *is not, in fact, steam properly; it is steam altered* by a certain degree of cooling; that is to stay, the substance that was steam is beginning to be condensed into water, in consequence of which it has become *visible vapour*. The steam, as it first issues from the spout of a tea-kettle, is transparent and invisible for nearly an inch; but then, losing part of its heat, it begins to be condensed into water, and becomes visible. The difference between the temperature of the transparent and invisible part, or real steam, and the visible cloud of vapour is sufficiently striking; the first would scald the finger if held in it, but the latter would feel merely warm. It is the state of actual transparent steam alone that is capable of cooking, and the vaporous state would be totally ineffective for this purpose. The steam in the interior of every steamer is always perfectly transparent, invisible, and dry, as much as in the apparatus above alluded to, but which is described as peculiar: were steam not so, it could not perform any effect in cookery. It is true that, when the lid is taken off such a steamer, a cloud of vapour appears; but this is because some of the dry and invisible steam is immediately partially condensed, and becomes *vapour* by the cold of the atmosphere. If a cold piece of meat be put into a vessel kept full of transparent steam, at first its coldness will cause the steam to condense upon it, and, of course, to moisten it; but when the meat is heated through up to the same temperature as the steam itself, it cannot occasion any such condensation; and the meat will then remain without farther moistening; real steam being, as we have said, always dry. It cannot be necessary, after this explanation, to notice the absurdity of supposing that dry steam is "steam not completely saturated with water." Dry steam has as much water as the visible vapour, but this water cannot appear as such until it is condensed. See this subject farther illustrated in describing the Rumford roaster, p. 814.

We have stated above that by means of steam, now so extensively employed in cookery, almost every process of the cook *may* be performed by this agent, but probably not with the greatest advantage, and therefore much judgment is required in its application. Even roasting and baking have been effected by high-pressure steam; that is, steam heated in close, strong vessels considerably above 212°, such as Perkins's steam tubes for warming buildings; but it is very doubtful whether this could be applied advantageously in domestic economy; and it is sufficient merely to mention it as a philosophical fact. Steam is, however, usefully employed in hot closets, hot tables, heating water for baths, drying clothes, &c.

Whenever steam is employed, its elastic power, when confined, should not be lost sight of, nor, indeed, any of its properties which we have described. It should be remembered that its force may be equal to that of gunpowder. In all boilers, therefore, for the generation of steam, there should be a safety-valve, which gives way and permits it to escape whenever its power becomes so great as to endanger the containing vessel, otherwise an explosion might be the consequence of its confinement.

4617. *In large kitchens, where steam is much employed,* and required for many purposes, it is the custom to fit up a boiler constructed nearly in the same manner as that for steam engines; but this requires the constant attention of a person experienced in the management of a steam boiler. It may be placed in an apartment adjoining the kitchen, since the steam can be conducted to any place by means of pipes; but care must be taken that all such pipes are accessible in case of any repair being necessary.

SECT. IX.—COOKING BY GAS.

4618. Among the novelties in the culinary art is the use of coal gas for producing the necessary heat. This method has a certain elegance to recommend it, and there are occasions when it may be found useful. Some persons have been so sanguine as to suppose that this employment of gas may soon do away altogether with the necessity of open fires in our kitchens: a hasty opinion evidently founded upon a very superficial and imperfect acquaintance with the business of an ordinary kitchen. Several experiments have been made, which prove that every process in cooking *may*, by the judicious application of burning gas, be effected; but this supposes a great variety of ingenious machinery, and cooks perfectly conversant with their use, to say nothing of the expense. What may be accomplished by future generations we will not at present venture to speculate upon; we know what can actually be done by any one determined to cook everything with gas, *at any* cost, but it is too much to think of its universal adoption at present, instead of the usual methods.

It will be interesting, however, to describe some of the experiments that have been made with success. The subject is at least amusing, and is really deserving of attention, even should its usefulness prove as limited as we fear it will ultimately be found to be.

Notwithstanding what we have just said, it is fair to observe, with respect to the flame of gas procured from the gas-works, that its regularity, the facility with which it can be obtained and conducted to any spot required, and the great nicety with which it can be adjusted in a single jet, or a series of jets, in a line, a circle, or several concentric circles, or any other figure, give it a superiority over every kind of lamp, and might almost tempt one to think that methods may some day be invented for applying it with success to culinary purposes with great advantage of convenience on some occasions, if not of economy.

4619. *To boil with gas on a small scale* is obviously extremely easy; nothing more is necessary than to make the flame play against the bottom of the vessel, *fig.* 685, which will be best if constructed on the principle of the Rumford tea-kettle, described in p. 706. It will be best to have several jets of flame, with separate stop-cocks, and then the boiling may be regulated by shutting or opening some of them. *Stewing* requires only less heat, and, of course, less flame.

Fig. 685.

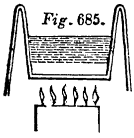

Fig. 686.

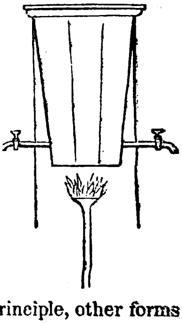

Already gas flame is found extremely useful in taverns and similar places for warming liquids and keeping them hot. The flame is made to play under a conical vessel, *fig.* 686, which is surrounded by a cylindrical one, to confine the heat round the sides of the inner one. The latter has sometimes partitions that divide it into several chambers, into each of which a different liquor can be put, and drawn off separately, by means of stop-cocks. The whole apparatus appears in form of a pedestal of any required shape, the flame being concealed in the interior; and it is also evident that, on the same principle, other forms of the apparatus may be constructed.

4620. *Roasting by gas* has been perfectly accomplished by the method for which Mr. Hicks took out a patent a few years ago; and this exhibits one of the most elegant modes of cooking. In this apparatus, *fig.* 687, the meat is fixed upon a spike in the midst of a circle of little flames of gas, and a bright copper cone being brought over the whole, the current of heated air thus produced, together with the reflection of heat from the inside of the cone, are sufficient to effect the roasting. The circle of flames is produced by causing the gas to come up through a pipe, *a*, which is fixed on a table, and fills a horizontal circular ring like that of a table lamp, having a number of small perforations on the top, through which the gas issues. The copper cone, not here represented, having an orifice at the top, comes over the stays, *b c*, and is suspended by a balance weight, so that the cook can let it down until it comes below the flame, or raise it up higher, in order to examine and view the meat. Beneath the circular tube giving out the flames, a shallow dish is placed, into which the gravy and melted fat fall, and then run out at *d* into another dish. *e f* is the meat stuck on the spike in the centre. Nothing can be cleaner or more elegant than this apparatus, by which a roast might be performed, if required, even in a sitting-room; and one advantage is, that the dripping is saved perfectly clean. But it is obvious that one apparatus is only calculated for things nearly of one size; and that for things of various sizes, several cones, or even several apparatuses, may be requisite. With regard to its practical use, we cannot consider it as productive of economy, or as much more than an elegant culinary toy, which may, notwithstanding, be occasionally useful, as an addition to the usual means of cooking.

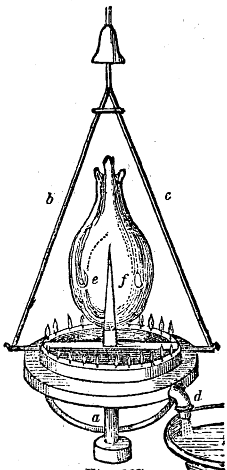

Fig. 687.

Fig. 688 represents *a gas apparatus for cooking*, which is an improvement upon the last, by enclosing the circle of gas flames with its reflecting cone in a cylinder of tin, from the top of which a pipe takes off the burned air; in this the gas is introduced below the apparatus. The door of the cylinder is represented as partly open.

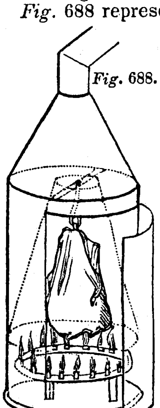

Fig. 688.

4621. *The following method of boiling by diluted gas* is said to have been first tried successfully at Edinburgh: A tube of sheet iron, *fig.* 689, A B, is made about two feet, or two feet six inches long, having its diameter from three to ten inches, according to the size of the vessels to be boiled. The upper orifice of this tube is covered with wire gauze, *c*, of about forty-five wires to the inch, fixed to an iron hoop. Three projections of iron, *a b*, come out from the sides of the tube just below this iron hoop, by which it is suspended and fixed in a hole cut in the top of a shelf or table, D E, for the purpose. The lower end of the iron tube is open, and a gas pipe, F, comes up a little way into it, and throws in a stream of coal gas, which mixes with the common air in the tube, and ascends through the wire gauze. This mixture of airs is explosive, but if it be set fire to as it issues *above* the wire gauze, its flame will not communicate with the mixture in the tube; because, on the principle of Davy's safety lamp, an explosion or inflammation of the gas cannot take place through the gauze. This flame, therefore, consisting of the burning of carburetted hydrogen mixed with common air, will give out a prodigious heat, and any vessel with water placed over it, having its bottom about two inches above the flame, will be made to boil. Cases, or tubes, of two or three inches in diameter will boil a tea-kettle, sauce-pan, or stew-pan; one of nine or ten inches diameter will boil a fish-kettle, or joint of meat, or heat water for a bath. The gas pipe should be furnished with two stop-cocks, one for the workman who fixes the apparatus, to regulate the greatest quantity of gas admitted, to which the cook should not have access, and the other by which the cook can diminish or shut off the gas. The point for regulating is the commencement of the appearance of the yellow flame on the top of the blue flame. If more gas be admitted after this, soot is deposited on the bottoms of the cooking vessels, from the combustion of the gas not being perfect; while, if due proportion be observed, the cooking may be performed without soiling the vessels, which may even preserve their original brightness, no soot being formed. It will be proper to enclose the sides of the table round the bottom of the thick tube, to prevent currents of air from disturbing the gas. It is necessary that great care should be taken

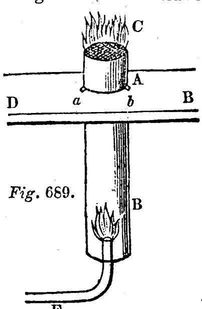

Fig. 689.

not to injure the wire gauze, since, should it get bent or broken, the flame would then communicate to the mixed gases in the tube, and perhaps a dangerous explosion might take place.

To prevent this accident, by protecting the wire gauze, some strew over it a layer of fragments of pumice-stone, which, being incombustible, protects it from any blow or other injury.

A hot plate has been heated by this gas; and it has also been employed to heat an oven.

It is obvious that it is only where gas is supplied *regularly* for illumination, that it can, in general, be available for the purposes of cooking; and that where no contrivances are employed to carry off the noxious gases generated, this use of coal gas must be more or less prejudicial to the health of those exposed to them. It cannot, therefore, be expected to succeed, except in the hands of persons whose scientific knowledge enables them to employ it with safety.

SECT. X.—PORTABLE COOKING APPARATUS.

4622. Various portable apparatus for cooking have been invented, some of which are useful on particular occasions, but none of them are equal to, nor ought to be described as perfect substitutes for the contrivances of an actual kitchen, although the inventors often hold them up to public notice in this point of view. The situations where they may be found useful and convenient are, when cooking is required in an apartment where there is no regular fitting-up for this purpose, in travelling, in camps, at sea, in picknick parties, and similar cases which may be easily imagined.

4623. *The Conjuror, or Camp Kettle.*—Some years ago, an apparatus of this name was very generally sold in London, where some may yet be found at the ironmongers, and is remarkable for the expedition with which a small piece of meat may be dressed in it; sufficient for one person may be done in less than five minutes; and a pint of water can be boiled in the same time, the only fuel being half a sheet of thick brown paper. In the interior of a cylinder of sheet iron, an iron cone like an extinguisher, perforated, is placed over a hole in the bottom, *c*, *fig.* 690, which represents a section of the apparatus. A shallow dish of tin, *b*, with its cover, holds the meat, suppose a beefsteak, and fits exactly into the top of the cylinder. There is a little door on the side, through which the paper wrapped round the cone is set fire to; the door is then shut. The heat of the flame being confined altogether within the cylinder, very soon cooks the meat, an effect which is assisted by the steam being confined by the cover of the dish. The smoke passes off by a pipe.

Fig. 690.

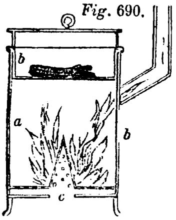

Fig. 691.

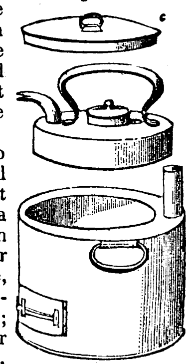

Fig. 691 exhibits a view of the apparatus, with its tea-kettle to fit in the cylinder; *c* is the cover of the round dish mentioned above. This little machine has been found extremely useful, not only in fishing or shooting parties, and other occasions where a dinner might be required at a distance from home, but likewise in numberless instances in the house where cooked meat or hot water may be wanted quickly, and when it is inconvenient to light a fire, particularly in summer. It is, perhaps, impossible to carry economy, convenience, and expedition farther than by this apparatus; but it must be admitted that by this process the meat is neither roasted, fried, baked, nor stewed; but it is completely *done*, and, with proper management, very palatable for those who have a good appetite.

4624. The little apparatus called *Fourneau*, *figs.* 692, 693, used much in Paris, and commonly employed by those who sell things in the streets, is extremely convenient, and would be found useful here on many occasions. It consists of an unglazed earthen-ware vessel, *a*, that bears the fire; in the cavity on the top some lighted charcoal is put; three little projections on the upper margin support the stewing-pan, *b*, also of earthenware, glazed within; there are holes in the lower one to supply a draught of air to the fire. By means of this very simple apparatus, poor people prepare their food, generally consisting of a stew of vegetables with a little meat; and a very small quantity of charcoal will keep this simmering for hours. It is to be observed that the noxious fumes of the charcoal render this apparatus improper to be used in a room,

Fig. 692.

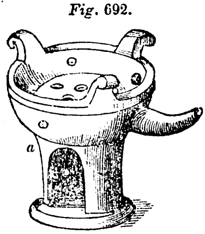

Fig. 693.

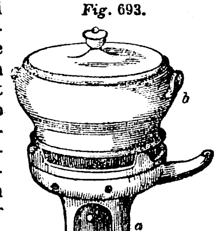
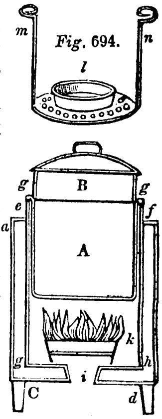


except there is a good current of air continually passing through; but it would be very useful in summer for cottagers, when it might be set out of doors.

4625. *Calefacteur Lemaine.*—A portable apparatus, so named from the inventor, for preparing *soup and bouilli*, has been much used in France, and is said to possess the advantages, not only of economy, and requiring little attention, but likewise that of making soup of a superior quality. *Fig.* 694 is a section. It consists of two parts, a cylindrical case with its little furnace, and the boiler fitting within it and holding the soup. The cylindrical case is double, being composed of two cylinders of sheet iron, one within the other, with a space between them; *a, b, c, d* is the external cylinder, and *e, f, g, h* the inner one; both are soldered together at the top. An aperture, *i*, is cut in the bottom of both, and these two holes are connected by a circular rim, which shuts in the space between the two cylinders. Over this aperture, *i*, is placed a small, circular dish of tin, *k*, with perforations in the bottom, containing charcoal or other fuel, which is supplied with air through the aperture *i*; A is the boiler, very little narrower than the space within the inner cylinder of the case; and this boiler has a rim round it at *g, g*, and three little projections corresponding to those openings in the upper part of the inner cylinder, which is higher than the outer one; when the boiler is placed so that the three projections correspond exactly with the three openings, the narrow space between the boiler and the inner cylinder is completely closed; but when the boiler is turned so that they do not correspond, then there is a narrow space open at *f, g*, by which the hot air and fumes of the charcoal can escape. To use this apparatus, water is first poured into the space between the two cylinders that form the case by means of a short tube at the top, closed with a cork, but not represented in the section; also, fuel is placed lighted in the circular dish. The meat and water are then put into the boiler, generally in the proportion of a quart of water to a pound of meat. The boiler is then placed in the case in such a manner that the three little projections do not correspond with the three little openings, so as to allow the smoke, or hot air, to escape, as was mentioned. In about thirty or forty minutes, according to the nature of the fuel, the water between the two cylindrical cases will begin to boil, which will be known by a little aperture and tube made at *b*; and by that time the water in the boiler will likewise be hot, though not boiling. It should be mentioned that a small shallow boiler with a cover, B, fits close on the top of the large one, A; when the water in A is known to be nearly boiling, the smaller boiler, containing water only, is taken off, the soup is scummed, and the vegetables and salt put in. The small boiler is now replaced, and the three small projections on the great boiler turned so as to correspond with the little openings, which allows the boiler to close up the aperture by which the hot air issued. The fire will now be soon stifled for want of draught; but, to preserve the whole as hot as possible, a large piece of baize, flannel, shawl, &c., is thrown over the whole, from the non-conducting power of which, and likewise of the water in the cylindrical case and the upper boiler, the heat of the expiring fire and of the air will be very long retained, even for several hours; during which time the soup will be very slowly and gradually kept at a simmering heat, but not boiling. Some have recommended that the boiler should not fit quite accurately into the case, so as to admit of a very slight draught to the charcoal fire the whole time; but in that case, provision should be made for the escape of the carbonic acid gas, which otherwise would collect in the apartment. The French mechanics, who are much accustomed to this species of cooking, find such an apparatus extremely convenient, as they can put it to work in the morning, leave it to itself, and find their soup ready and excellent when they return to dinner.

Fig. 694.



The boiling water between the two cylinders of the case is for washing the dishes, or any other such purpose, and is drawn off by a cock on the outside. That in the upper boiler may be employed in a similar way, or for cooking something else.

This principle may be varied in many ways. Instead of water between the two cylinders of the case, the space might be filled with charcoal dust, and a tube made from it to conduct away the smoke, and then wood, or even coal or coke, might be burned, if the apparatus is placed under a chimney, or in the open air, and a steamer might be put upon the boiler. By an addition to this apparatus, meat or poultry may also be dressed in a mode somewhat resembling baking, but what the Parisians term roasting; *l* is a flat, circular dish fixed upon a perforated rim, and into which the meat is laid. This dish is now let down into the cylindrical case instead of the boiler, and is suspended at a proper height above the fire by the handles.

4626. *The Bruges stove*, used sometimes in the cottages in Holland and the Netherlands, may be mentioned among other portable apparatus of this kind. This stove consists of a cylindrical case of cast iron, containing a small furnace and ovens. *Fig.* 695 is a section of the stove, and *fig.* 696 a perspective view of the exterior, in which *a* is the furnace, or fire-place, supplied with air by a hole at the bottom, *b*. This fire-place being closed at the top by a cover, the smoke or heat passes through a square aperture represented in the section into the spaces *d, d*, immediately under the flat top of the apparatus, which it heats, and then passes off into a flue up the chimney. The space, *e, e*, round the furnace forms an oven heated by the iron fire-place, *a*. The doors, *f, f*, open into this oven, which serves for baking bread or meat. The top of the apparatus above *d d* serves to set vessels upon for boiling or stewing, the heat coming through the iron being sufficient for that purpose. If much heat is required, the vessels may be placed in circular openings, *g, g, g*, in the top, which otherwise are closed by iron covers, and the top then answers for the hot plate now in common use. The whole stands upon strong iron feet; *h* is a register for the air which supplies the fire; and the fire-place itself may be increased or diminished by employing various-sized circular grates adapted for different parts of the conical furnace; *b* is a moveable drawer into which the ashes drop. The economy of fuel, which may be coal, is evidently considerable in this apparatus; and there may be numerous cases where it may be found convenient and useful, particularly where fuel is dear; and the great heat given out by an iron stove is not objectionable; but it must be observed that, as the heat produced in the apartment by this apparatus, when in operation, must be very great, this must be taken into consideration in applying it; and, indeed, it is usually employed as a warming as well as a cooking apparatus. With this view it should be placed in the chimney, or just outside, the iron pipe which carries off the smoke being inserted into the flue in the usual manner. In this case, however, all the objections to defective ventilation will remain in full force, and likewise the danger of frequent overheating, particularly if used in summer for cooking. We cannot, therefore, recommend this machine for our English cottages, since many other arrangements may be contrived nearly as economical, and much better calculated to promote a change of air, so necessary to health. As an addition to our usual kitchen furniture, it is much inferior to other plans in common use; its great weight is an objection. It may be useful

Fig. 695.

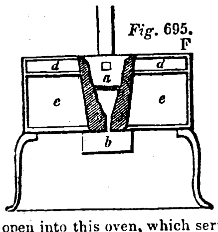


Fig. 696.

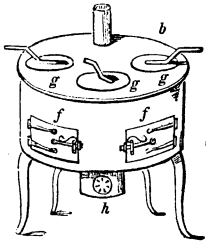

Fig. 697.

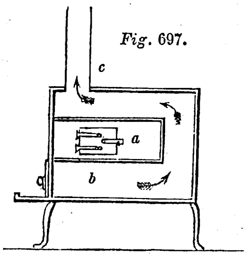


to acquaint those who wish to try this stove that it is manufactured by Messrs. Cottam and Hallam, Winsley-street, London, and costs about eight or ten pounds.

4627. *An iron stove, serving also as an oven, is used in the United States, fig.* 697, and is described by Dr. Arnott. This stove is square, and has an iron box in the middle, which is the oven; the wood fire burns at *b*, beneath, and the flame circulates in the direction of the arrows, the smoke going out through the flue, *c*. This serves also to warm the apartment, but has the usual defect of iron stoves.

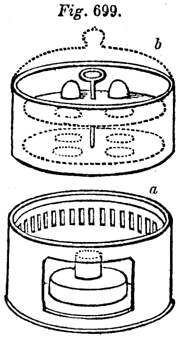
4628. *Cooking by means of a Lamp.*—Among the many resources of the culinary art produced by necessity, or which ingenuity has suggested, is that of performing most of its operations by the heat of a lamp only. The native inhabitants of those regions nearest to the poles, the Esquimaux, who have not the advantage of either coals or wood for fuel, have the ingenuity to employ fish oil burned in lamps made of stone, both for warming their habitations and for cooking their food. Lamps afford a very convenient mode of applying heat on many occasions. The dressing of food may thus be effected in situations where an ordinary fire cannot be had, as on ship-board in stormy weather, in camps, or in travelling. Lamps may be considered as portable furnaces, capable of giving much more heat than is generally supposed. They are made in a variety of forms, adapted to the kind of fuel and the particular objects for which they are employed.

4629. *The spirit lamp* is the most elegant, and, though too expensive for the ordinary operations of cooking, is much employed in certain cases, more particularly in heating a small quantity of liquid, or keeping liquids hot, as in the instances of tea-kettles and coffee-pots, &c.; but cases have occurred at sea and in camps, and in travelling, where the spirit lamp has been adopted as the most convenient. Although the flame of spirit of wine is pale, and gives very little light, it affords considerable heat, and it possesses the important advantages of not giving out the least smell nor smoke, and, of course, of not depositing any soot or stain upon the vessels to which it is applied; indeed, such a lamp was employed with advantage by Captain Parry in his northern voyage. Oil is the general fuel for lamps of this kind; but tallow may likewise be employed, and, indeed, any kind of fat; but such lamps must be of the most simple kind, otherwise the wicks would get clogged. A circular dish or basin, having several wicks at the edge, may be used.

Fig. 698, the construction of the Rumford tea-kettle, with an external cone, *c*, will be found the best adapted for a boiler to be heated by a lamp, the flame playing under the bottom of the interior part.

Fig. 698.

Fig. 699.



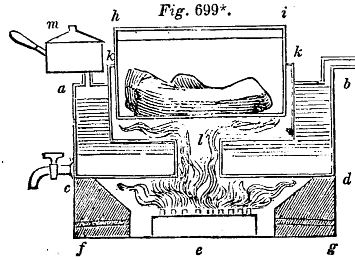
4630. *The chemist's lamp*, on the Argand principle, may likewise be employed as an excellent mode of obtaining heat; and it may be observed that the *double*, or *concentric-wicked Argand lamp* affords so intense a heat that it may be applied to a great variety of culinary operations where portability and great heat are required.

The portable furnaces of the laboratory, of which there are many kinds, may also be used with advantage in many culinary processes.

4631. *A portable apparatus for boiling by a lamp* is represented in *fig.* 690; *a* is a receptacle for the lamp; and the best for this purpose is the chemical Argand lamp with the short copper tube, this affording much the strongest heat without smoke. On this fits the vessel *b*, of tin or copper, to hold the meat to be boiled, or soup to be made; *a*, a stand for holding eggs, as is shown in the cut: the cover is represented by the dotted line, or instead of this may be placed the tea-kettle, *c*.

4632. *An extensive portable cooking apparatus* has been made upon this principle, by which roasting, boiling, stewing, and cooking by steam may all be performed at the same time, the fuel being only an oil lamp; *a, b, c, d, fig.* 699*, is the section of a cylindrical vessel of sheet iron placed over a lamp, with a number of small wicks, *e*, and resting upon a circular stone hollowed out for the lamp, or on an enclosed frame of iron, there being a series of holes all round to admit air to supply the lamp. Within the vessel, *a, b, c, d*, which contains water, another iron vessel, *h, i*, is suspended, to the bottom of which the flame of the lamp is admitted through an aperture, *l*, in the bottom of the boiler with water. The smoke passes off through a minute crevice at *k, k*. It is evident that the flame of the lamp, being so much confined, will produce a powerful effect upon the water in the boiler, and likewise that covering the aperture *l*; it will strike upon the bottom of the vessel *h, i*, in which meat is put upon a stand to roast. If this vessel be di

Fig. 699*.



vided into two by a partition, one half may boil, or the steam may be conducted by means of the pipe *b* to another where the boiling may be done; indeed, sufficient steam may be generated in this way to boil the water in a number of other vessels, and the steam may be admitted into others for cooking by steam. Small saucepans for gravies, &c., may also be fitted on all round, as at *m*. In short, it is easy to see that, upon this principle, with only a strong lamp, cooking may be performed in many ways, and an excellent dinner prepared; but it cannot be pretended that the roasting can be equal to what is done before an open fire. Such an apparatus is very applicable to a ship or to a camp; and for the former, it has been made to swing like a ship's compass. But though we point it out as a contrivance that may be exceedingly useful in such situations, it is absurd to speak of it as one that should supersede the ordinary kitchen, particularly when we consider the cost of the apparatus, which must necessarily be considerable. Something of this kind was manufactured by Mr. Jose, of Bond-street, London, and we believe was invented by Lord Cochrane.

4633. *As an occasional method of keeping anything hot for some time*, may be mentioned placing it in a vessel of sheet iron filled with sand, in which is buried a red-hot iron heater. The non-conducting property of the sand will retain the heat for a considerable time, and will not cause any unpleasant fume like charcoal. See *a*, *fig.* 700.

Fig. 701.

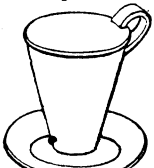


Fig. 700.

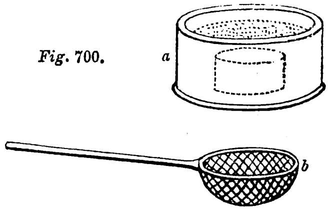

4634. *Heat may be occasionally applied to a particular part* of any object by means of an iron ring handle, *b*, *fig.* 700, to which is attached a cup of iron wire that can be filled with live coals.

The little machine called *an Etna*, *fig.* 701, may be mentioned, for the purpose of warming or boiling water in a few minutes. It consists of a tin vessel, in form of an inverted cone, to hold the water, and this is placed in a cup of tin, into which a little spirit of wine or naphtha is poured, and set fire to. The flame striking against the sides of the cone, very soon causes the water to boil. The handle is made to go inside when packed up for travelling.

CHAPTER IV.

FURNITURE OF THE KITCHEN AND OTHER OFFICES.

4635. In the following account of kitchen furniture, the principal things only are described, together with such as have any novelty, or are not very generally known; there are many other small articles with which every family is familiar, and which it is not necessary to mention; but almost all of these will be found in the general list of furniture at the end of this section.

4636. *Kitchen Tables.*—There is generally a very strong, well framed table, with stout legs, placed in the centre of the kitchen. In large kitchens, the top is frequently made of thick elm, for chopping and cutting upon. Smaller tables may be placed along the walls, as is found most convenient. Where economy of space is an object, some may consist of flaps to hang against the walls, to be used occasionally, *fig.* 702, and these are sometimes made to serve as ironing boards. The top, when lifted up, is supported by a jib bracket leg of wood, or an iron rod.

Fig. 702.

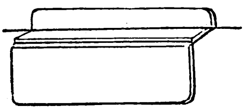

Fig. 703.

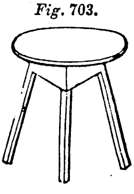

4637. *Cheap round tables* may be made, like *fig.* 703, with only three legs, which have this advantage, that they stand steadier on an uneven floor than those with four legs. The legs may even be branches of trees cut to the length, and the top may be square.

4638. *The kitchen dresser* is a strong side-table attached to the wall, with shelves over it serving as a plate rack, *fig.* 704; on the upper side of the shelves, close to the front edge, there are fillets of wood to prevent the plates from sliding off; and there are a

Fig. 704.

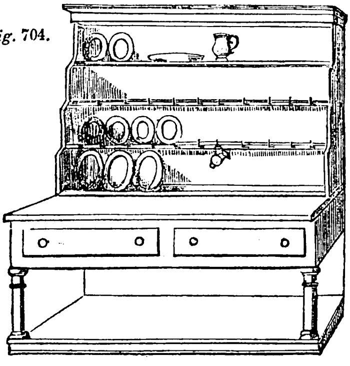

Fig. 705.

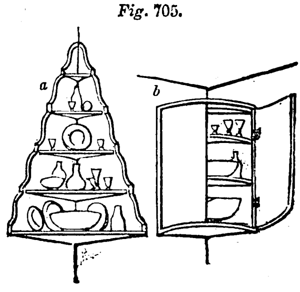
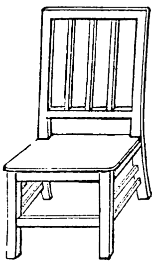


number of hooks on the edges of the shelves to hang small jugs and other things upon. At the bottom of the dresser is the pot-board for placing sauce-pans, tea-kettles, and other things put upon the fire; this part is always painted black. The dresser itself and plate rack are best painted stone or wainscot colour. Instead of the pot-board, some prefer having below the dresser a system of drawers and shelves, enclosed by doors, for holding knives and forks, spoons, spices, and various things necessary for the cook; or there may be one dresser with a pot-board, and another like that just mentioned.

4639. *Closets or cupboards* of some kind are essential in a kitchen, as well as in various other offices. Some are fixtures constructed with the house. *Buffets*, or corner cupboards, *fig*. 705, *a* and *b*, were much in use in days of old, but now are seen only in the cottage or old farm-house. They were used for holding the punch bowls, glasses, and china; but might occasionally be found useful in some of the offices, particularly when there is a deficiency of room. In short, conveniences of this kind must be regulated by the wants of the establishment and the plan of the offices, so that no rules can be established.

4640. *The common kitchen chairs* used in and about London, *fig*. 706, are made strong, of beech or elm, put well together with mortises and tenons, and are not painted, but kept clean by scouring. They are chiefly made in the country.

Fig. 706.



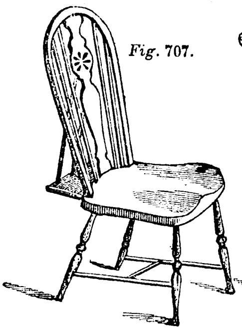


Fig. 707.

Fig. 708.

4641. *The Windsor chair*, *fig*. 707, is much used as a kitchen, and likewise as a cottage and garden chair in many parts of the west of England. The seat is made of elm, a little hollowed out; the outer rail of the back is of ash, in one piece, and bent to the form, its end being inserted into the seat. An additional support to the back is given by two round rails made fast to a part of the chair which projects behind. These chairs are remarkably strong, as well as light and cheap. *Fig*. 708 is another variety of the chair, of a simpler shape; the back rails are made stouter, and have no occasion for the support behind.

4642. *Benches* are long wooden seats with backs to them, *fig*. 709, useful in servants' halls, lobbies, and similar places.

Fig. 709.

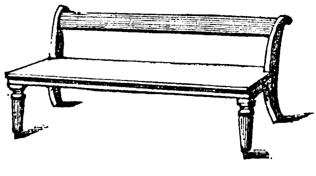

Fig 110.

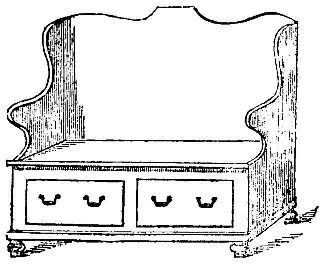

4643. *Settles* are old-fashioned seats, with high, close backs, to defend those who sit in them from any cold draughts of air, *fig*. *710*. They were formerly common in the corners of the large cottage chimneys, and the seat formed a chest for containing household articles; drawers may be substituted as more convenient.

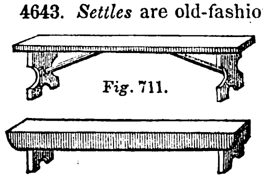

Fig. 711.

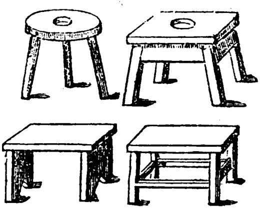
4644. *Forms*, *fig*. 711, are the simplest and cheapest kind of seat for a number of persons; and when covered with baize or carpeting, are often made to accommodate in assembly rooms, &c. They may be quickly got up on occasion.

4645. *Wooden stools*, *fig*. 712, are frequently useful for many purposes in the kitchen.

Fig. 712.



4646. *Kitchen knives, forks, and spoons* are well known. There are various knives peculiar to the cook sold at the ironmongers'. Spoons for stirring should be of wood; as those of metal, by wearing, leave some of their substance in the food, which, though small in quantity, is best avoided. Forks and spoons for mixing salad ought, particularly, to be of wood; these the French are very skilful in making.

4647. *The earthen-ware dishes and plates* required by various families are so well known to housekeepers that it is unnecessary to describe them in detail, particularly as they are varying in fashion continually. We refer the reader to the section on "Earthen-ware" for a general account of the manufacture.

4648. *Sinks* belong properly to the scullery and wash-house, but in small kitchens are frequently placed there also, or in the back kitchen. Their use is to wash dishes in, or other articles, and likewise to receive and convey away the dirty water. They are best hollowed out of a single piece of stone, *fig*. 713, but are likewise made of wood lined with lead or zinc. It should be placed, if possible, in a good light; should be supplied by a cock with cold, and if there is convenience, also with hot water. The waste pipe should pass below into a drain, and there should be there a bell stench-trap to prevent any bad smell rising. There should likewise be a sink in the butler's pantry, which might be in the corner, *fig*. 714; also one in the servants' hall; and if this were furnished with a stop-cock and plug in the bottom, it might serve occasionally for washing hands or anything else.

Fig. 713.

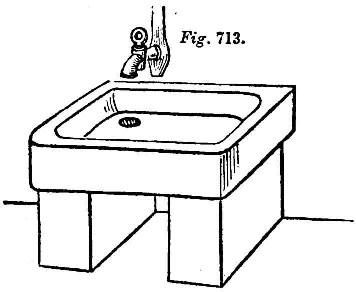


Fig. 714.

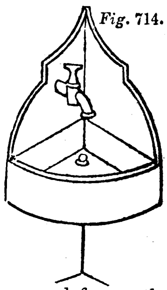
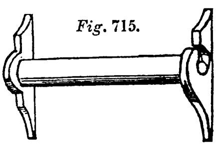


4649. *Towel rollers*, *fig*. 715, are generally fixed in kitchens, to hang kitchen towels on, and frequently the door is selected to contain them, as saving the wall for something else. The roller takes out to put on the towel.

Fig. 715.



4650. *Hot Closets*.—One of the improvements in modern kitchens is the facility with which the various dishes are kept hot when they are ready before they are wanted; this is effected by means of hot closets, which are indispensable when large dinners are prepared. A hot closet is merely a closet with shelves, *a b*, *fig*. 716, of a size proportioned to the number of dishes, kept very warm in the inside by flues or steam. Several examples of these may be seen in our subsequent representations of kitchen arrangements. They are sometimes made of cast iron, and placed in a recess over the kitchen oven or roaster, and heated by the smoke and heat that has come from the oven. They may also be heated by steam after it has served to heat boilers. The smoke, or steam, circulates in a space around the outside of the closet, *c*, *d*, *e*, *f*, coming in at one point and going out at another; the doors, which are not represented in the wood-cut, being kept shut. The dishes are placed upon the shelves.

Fig. 716.

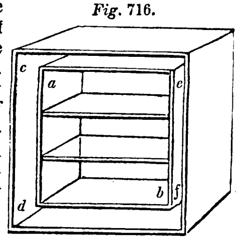


Fig. 717.

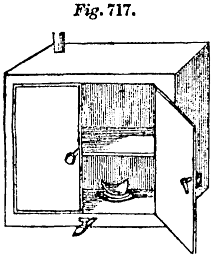
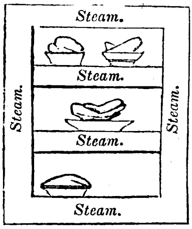


4651. *Fig*. 717 is a portable hot closet, heated by steam, made entirely of tin plate. The outer case consists of two thicknesses of tin plate, having the steam between: a pipe from the boiler conveys the steam to the apparatus, and the condensed water runs off by a pipe with a stop-cock at the bottom.

4652. *A hot closet may also be made* in the screen that stands before the kitchen range, by various modes. A screen with a closet within being constructed on the principle of the above figure, steam is conveyed by a pipe in the floor, and introduced into the space between the closet and the outside casing, the condensed water passing off by another pipe.

Sometimes, when more heat is required, steam is not only car ried all round the hot closet, but even in the shelves, as in *fig.* 718; these being of tin, and double, with the space between about an inch and a half.

Fig. 718.



4653. *An economical and excellent hot closet* is formed by taking a common screen for placing before a kitchen fire when meat is roasting, and closing up the front or side next the fire with sheet iron blacked; forming a door at the back for putting in and taking out the articles to be kept hot. As black iron absorbs the heat powerfully, the air inside, not being able to escape when the doors are shut, becomes very hot. When it is desired to use this hot closet as a hastener in roasting meat, it is only necessary to hang in front, before the black iron, a covering of tinned sheet iron, which may be in two or more plates, according to the size of the hastener, for convenience of lifting on and off. *Fig.* 719 is a back view of such a moveable hot closet, with the door open, showing the shelves, &c. In many cases, white sheet iron will be preferable to black iron, because, while it reflects the heat and hastens the meat, it will conduct and radiate quite enough into the hot closet; and what is collected there will not so easily escape again as through the black sheet iron; this kind of hot closet, it should be observed, is liable to an inconvenience; the wood shrinks so much by the great heat of the fire, that draughts of cold air penetrate into it; these openings, when they occur, must be stopped up by the carpenter, except he is ingenious enough to provide a better remedy. It may not be necessary to have the whole of the screen converted into a closet for keeping the cooked dishes hot: the upper half alone may be found sufficient, and the lower part may be used as a plate warmer, in which case two sets of doors will be proper.

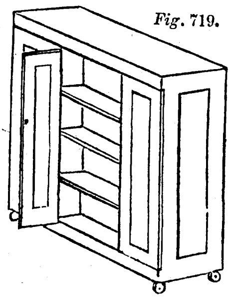


Fig. 719.

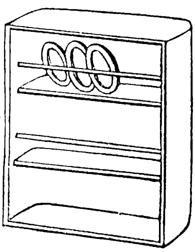
4654. *Plate warmers* are quite necessary in establishments where hot closets are not used in the kitchen, and frequently in the dining-room. Those used in the kitchen may be fitted up in the fire-screen on a small scale, as in *fig.* 720; those are made of wood lined with tin, and may have a door in the back to take out the plates and dishes

Fig. 720.



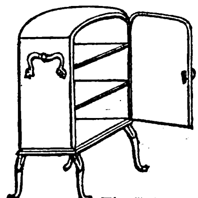


Fig. 721.

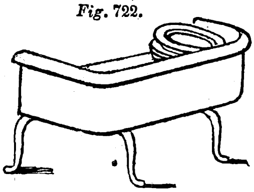
Fig. 721 is the well-known japanned plate warmer for the parlour in small families. *Fig.* 722 is a lower kind sold in the shops under the name of *vegetable warmers*, for keeping those dishes of vegetables warm that are not put upon the table. They are set down before the fire.

Fig. 722.



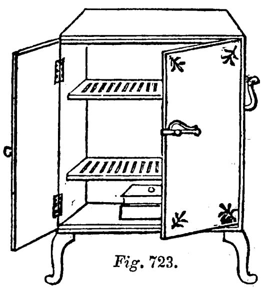


Fig. 723.

4655. *Plate warmers are now constructed*, as *fig.* 723, in which a vessel filled *with burning charcoal* is placed to keep plates and dishes hot; and these are sometimes placed in the dining-room. Although they are found effective for their intended purpose, we cannot recommend the employment of charcoal in this way, since its fumes are so extremely prejudicial, which must add much to contaminate the air, where already several causes, such as respiration and lights, tend to injure it. *An iron heater placed* in such a receptacle *would not have any bad effect*, and though this would not keep hot so long as charcoal, yet, with good management, the heat given by it to the plates will generally last sufficiently long at private dinners. We have seen one fitted up like an elegant piece of oak furniture with carving, *fig.* 724, which remained always in the dining-room, and the use of which could not be suspected. The heater was placed in it just before dinner commenced; and it might easily be renewed without its being observed. It is scarcely necessary to add that it was lined with tin, and had shelves.

Fig. 724.

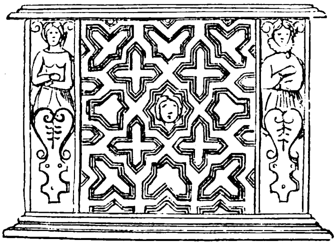

Fig. 725.

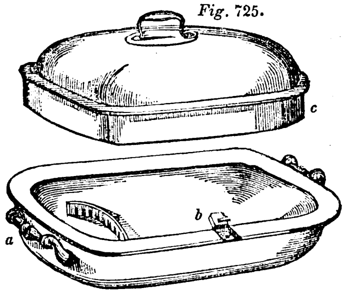

4656. *Hot water dishes, a, fig.* 725, are used for certain large joints of meat, hashes, and various other things. They are formed by having a reservoir for hot water beneath the dish itself, the water being poured in at *b*. *c* is the cover.

4657. *Gravy kettles, fig.* 726, are for keeping gravies hot to pour over various dishes as they are cooking; they are of copper, and are heated over the charcoal stove or hot plate.

Fig. 726.

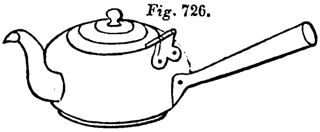

Fig. 727.

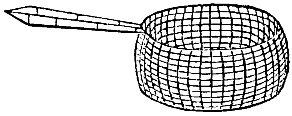

4658. *Wire baskets, fig.* 727, with wire handles, are for crisping parsley, or any similar thing, over the fire.

4659. *Spoon drippers, fig.* 728, are for hanging large spoons and ladles on, with a trough below to catch the drippings, that they may not soil tables if laid on them; it is made of tin, and fixed against the wall.

4660. *Glaze-pots, fig.* 729, are for keeping the strong meat jelly called glaze; this is put into a tin vessel that is inserted into another containing boiling water, in the manner of a glue-pot; a hole in the lid is for the brush.

Fig. 728.

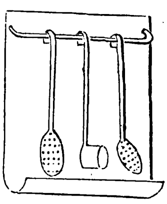

Fig. 729.

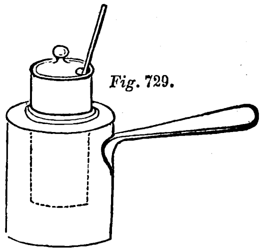

4661. *Spice and Flour Boxes.*—In cooking, frequently a few minutes are of great value, and the loss of them a serious inconvenience. It is essential, not merely to the comfort of the cooks, but to the perfection of their processes, by enabling them to acquire precision, that all their apparatus, even apparently of the most trifling kind, should be well contrived for expedition. In a well-furnished kitchen, such as alone will enable the cooks to get up the best dinners, everything should be studied as in a chemical laboratory.

Fig. 730 is a tin box with three divisions: the largest for flour; and of the two smaller, one is for pepper, and the other for salt. *Fig.* 731 is also a tin box with several divisions, for pepper, salt, both mixed, and also for various spices for immediate use, and which are to be always at hand. Tin spice-boxes, with divisions for keeping various kinds of spice, are sold at the ironmongers'.

4662. *Mortars and pestles* are necessary. In considerable establishments, large mortars of marble, placed upon a firm stand, are requisite. Smaller mortars of brass are likewise used.

Fig. 730.

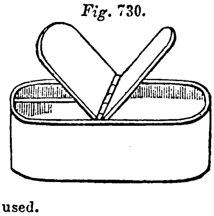

Fig. 731.

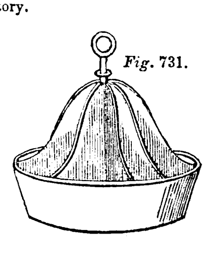
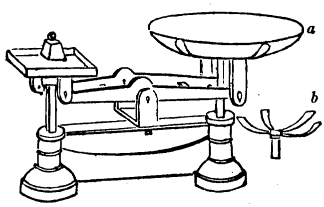


4663. *Machines for weighing* are very necessary in every family, that the housekeeper may keep a check upon the tradesman, and for proportioning various ingredients.

The common scales are too well known to require description. *Fig.* 732 is a weighing

Fig. 732.



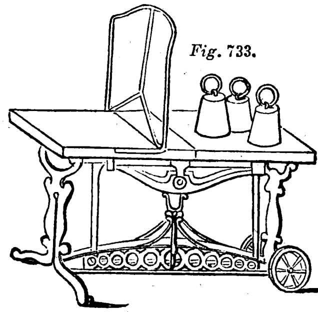


Fig. 733.

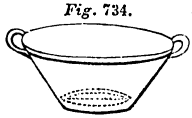
machine now generally used as much more convenient. The articles to be weighed are put into the scale, *a*, which lies loose on a cross-piece similar to *b*. The weights are put into the square dish, *c*, and when it descends it gives the weight required. The construction, on the principle of the lever, is easily understood from the figure.

Fig. 733 is a weighing machine generally used for domestic purposes, where larger and heavier articles are to be weighed. It will weigh three hundred weight. Both the above are constructed wholly of iron.

Fig. 734.



4664. *Cullenders*, or *colanders*, *fig.* 734, are vessels having the bottom pierced full of holes, for straining or separating the more liquid from the solid part of substances.

4665. *An iron hand-mill*, securely fixed to the wall, is necessary for grinding coffee, and another for rice flour, barley flour from pearl barley, or oatmeal from groats; and a smaller hand-mill for pepper, &c.

4666. *Cinder Sifter.*—Scarcely anything is more destructive to the furniture of our apartments than taking out the ashes from the grates in the morning, from their flying about, and raising a cloud of dust that afterward settles down over every part of the room, and has to be removed by careful brushing and wiping; but the great mischief generally done by this, which is too often performed in a careless manner, is seldom sufficiently understood, because the operation is performed early in the morning, and the rooms are dusted afterward. We would recommend, therefore, that a cinder sifter should constantly be a part of the housemaid's apparatus. This simple machine, the cost of which is trifling, will not only prevent almost all the destruction we have mentioned, but will save the housemaid herself from the dirt inseparable from the usual mode, and, what is not undeserving of attention, economy and the cleanliness of the fire will be promoted; for when the ashes are taken down without being sifted, a great deal of good cinders go into the dust-hole, in spite of the endeavours of the most careful servant. The best cinder sifter is made of tin in the form of a slop-pail, but larger; in the inside is a wire sieve that takes out. The ashes being put into this sieve, the lid of the pail is put on, and by turning round and shaking the latter, the ashes fall through, leaving the cinders alone in the sieve. The pail should now remain quiet for a few minutes till the ashes subside, and then the lid may be taken off, and the cinders used to put on the fire: or, if that is not required, they may be kept for other fires or coppers, and the ashes thrown into the dust-hole. A cheaper kind of cinder sifter is made of wood; but the principle is the same. Considering the great convenience of this little instrument, it is surprising that it is not employed in every family.

4667. *Bellows.*—The use of bellows is frequently declaimed against in good housewifery, and certainly the fires may be managed perfectly well without the use of this apparatus; but there are, nevertheless, occasionally cases where they are extremely convenient.

4668. *The common bellows for blowing the fire* is a very ancient and a very simple and ingenious invention.

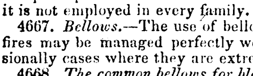


Fig. 735.

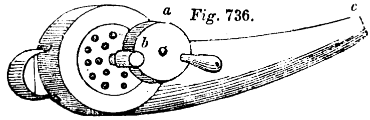
The principle on which it acts is its forming a vacuum, into which air rushes to fill it up, which is afterward expelled through the nozzle in a stream, by pressing the two boards together. It consists of two flat boards, *a* and *b*, *fig.* 735, united by a leather joint at *c*, and having leather nailed on the edges, so as to permit the boards being separated at one end. On the inside of the circular hole, *d*, in the lower board, a leather valve is fastened, which permits the air to enter when the upper board is raised, but shuts when the boards are brought together, and thus obliges the air to be driven out at the nozzle. This simple apparatus affords a good illustration of the fact that air is a substance as well as water; for having raised the upper board, as in blowing, and stopped up the nozzle, it will be found that it is impossible to shut the bellows, the air within resisting as much as if it were water, which could not be the case were the air not substantial matter.

4669. *The double bellows* is mostly used for the forge; but it is occasionally employed in a portable form in the same way as the single just described. In this there is another board in the space between the upper and lower ones; and there is a valve opening upward, likewise, in the middle board. By this means a continuous blast is produced; but this construction is generally too heavy for domestic use.

4670. *Clarke's patent blower*, *fig.* 736, is a great improvement on the double bellows, producing a continuous blast, but being at the same time very light and cheap.

Fig. 736.



It consists of a tin tube, having attached to it a barrel, in which is contained a circular fan like that used for winnowing, and which is driven round by a wheel, *a*, rubbing against a smaller one, *b*, fixed on the axis of the fan. The air enters at the holes on the sides of the barrel; and the leaves of the fan reaching close to the *interior* circumference of the barrel, the air is expelled in a continued stream through the tube, *c*. This apparatus blows up the fire much better than the common bellows, which, if used injudiciously, sometimes puts the fire out.

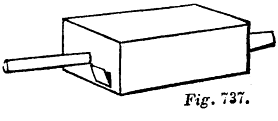


Fig. 737.

4671. *The Chinese bellows* consists of a box of wood about two feet long, *fig.* 737, and one foot square, in which a thick square piece of board, which exactly fits the internal cavity of the box, is pushed backward and forward. In the two ends of the box, and in the internal board, there are valves to admit and expel the air; it is, in fact, a kind of pump. *A single tube*, like a gun-barrel, was, perhaps, one of the first instruments for blowing the fire, and is still generally used in the cottages in the north of France.

4672. *Cast iron stands, with revolving tops, fig.* 738, are useful to place things on occasionally before the fire to keep hot; by the top being moveable, the several sides of the dish may be presented to the fire very conveniently.

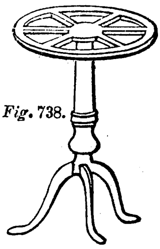

Fig. 738.

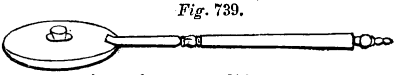
4673. *Brooms and brushes* are articles of furniture in daily use, and are made of various materials, as whisk, hair, cane, whalebone, &c., and of a great variety of forms, according to the uses to which they are applied. They are too well known to require particular description, but may be enumerated as *carpet brooms*, made of a strong white grass, termed whisk; *chamber brooms*, made of long hogs' bristles; *hand brooms; bannister brooms; Turk's head*, with a very long handle, for sweeping down cobwebs and dust from cornices, &c.; *feather brooms*, for dusting pictures and delicate articles; *hearth brooms*, both plain and ornamented, some of which are made with the handle to shut up short like a telescope, for drawing and bed rooms. There are brooms for offices, yards, and areas of birch, some of which are made for this purpose in the form of chamber brooms, but of the inside of the canes called ratan, after the outside has been stripped off for the seats of chairs; these are extremely effective and durable, as well as cheap. The bed-chamber brooms should be kept in a closet on the bedroom story for them and other similar utensils.

4674. *Brushes* are smaller, and have the hair shorter than brooms; they are usually made of hogs' bristles of different degrees of coarseness and fineness, and of various lengths. The hair is doubled and fixed into holes by wire, which is usually concealed by a thin plate of wood that covers it. In ill-made brushes, this covering is apt to come off and expose the wire, and when this fails the hair comes out; should this accident happen, the wood covering should be fixed on again securely. In some brushes the hair is merely fixed into the holes by some cement; these are generally worthless. The various brushes in common use may be enumerated as clothes-brushes of various kinds, hat-brushes, coarse and fine, shoe-brushes, nail-brushes, tooth-brushes, crumb-brushes, bottle-brushes, scrubbing-brushes, dry loaded rubbers for floors, black-lead-brushes for grates, furniture-brushes, dusting-brushes, water-closet-brushes, and filtering stone-brushes.

4675. *The common warming-pan* for beds is filled with live coals, and it requires care not to leave some smoke and suffocating fumes, independently of the danger of scorching the sheets.

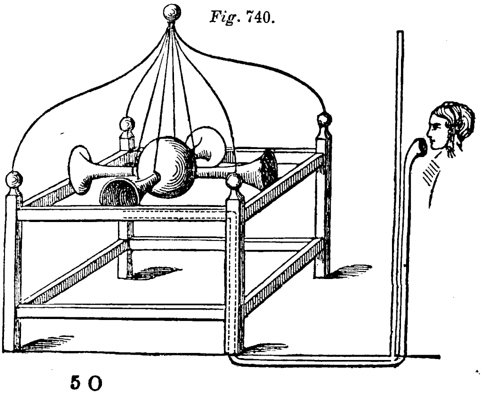
A superior warming-pan, fig. 739, is filled with boiling water, which is perfectly safe from all these accidents.

Fig. 739.



4676. *Tubes for speaking through*, so as to communicate between different apartments at some distance from each other, are at present much employed in shops and manufactories, and, as they instantly convey intelligence or orders to the remotest parts of an establishment, save an immensity of fatigue, and produce a great economy of time. They have not yet been much introduced into domestic establishments; but they would be found extremely advantageous in large houses, in conveying orders from the nursery to the kitchen, or from the house to the stable. Mr. Babbage observes, "their convenience arises, not merely from saving the servant or workman useless journeys to receive directions, but from relieving the master himself from that indisposition to give trouble, which frequently induces him to forego a trifling want, when he knows that his attendant must mount several flights of stairs to ascertain his wishes, and, after descending, must mount again to supply them. The distance to which such a mode of communication can be extended does not appear to have been ascertained; but it is probably much greater than is required in the largest mansion." The tubes are usually made of tin, and about an inch and a half in diameter, with a conical piece at the end for speaking into; the person spoken to puts his ear to the other end of the tube; and a bell is used, the ringing of which is a signal to listen. Tubes for this purpose have lately been made of India rubber.

Fig. 740.



4677. *These speaking tubes first came into use here in consequence of the singular exhibition*, about thirty-five years ago, of what was called the *Invisible Girl*. In an empty room was seen an apparatus resembling a large ball, having four speaking trumpets attached to it, the whole being suspended by silken strings in the middle of a frame-work, nearly of the form of that of a tent bedstead, *fig.* 740, in no part of which was it possible for a human being to be concealed. If a visiter applied his mouth to either of the trumpet mouths, and asked some question, a reply was given by a voice which seemed to proceed from the ball, which occasioned the name, the Invisible Girl. Although this illusion created much curiosity in the public, and the apparatus was examined for months by numerous ingenious persons, yet no one hit upon the mode in which the effect was produced, it not being then generally known that sound could be conveyed through tubes, and the tube through which the sound was really conveyed being concealed. The following, however, was the construction of the apparatus: the frame-work contained a metallic tube, indicated by the dotted lines, and this tube passed under the floor into an adjoining apartment. The person who gave the answer to a question put at the trumpets applied his mouth to the end of this tube, and the sound was conveyed by its means to the points in the frame opposite to the trumpet mouths, which they entered and were reflected back, and seemed, therefore, to issue out of it. When the effect of this conveying tube became publicly known, the exhibition ceased, and tubes have, since that time, been very generally employed to convey the sound of the voice, as above mentioned.

4678. *A clock* should never be omitted in a kitchen. For those who wish to be economical, a Dutch or German clock, with wooden wheels and ordinary weights, which may be had for 12*s*, and some of which perform remarkably well, will answer every practical purpose. The alarum which is frequently attached, and which can be set to go off at any required hour, may not be without its use.

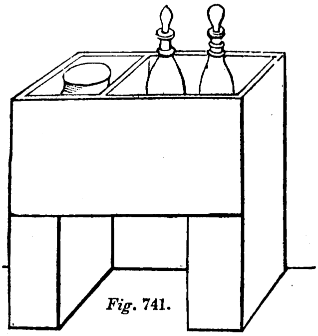


Fig. 741.

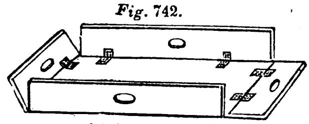
4679. *A wine and butter cooler* (*fig.* 741) is often useful in some cool place adjoining the wine-cellar or ice-cellar, into which a quantity of ice may be put for daily use, and to which access can be easily had, for cooling wine and butter. It may be of wood lined with lead.

Ice Preservers.—For the description of these, see Book VIII., Chap. VII., "On Cooling Liquors."

4680. *Dish covers, of metallic wire gauze,* are very useful for covering up meat, either raw or cooked, to keep off flies, and yet give a view of what is below.

4681. *Butler's trays* are made of mahogany, and are more convenient to put away, occupying less room, when they are made to fold down, as in *fig.* 742. When used, the sides are turned up and fixed by bolts. It is recommended that, though the sides may be of common Honduras, the bottom should be of Spanish, as the soft wood is too easily stained.

Fig. 742.

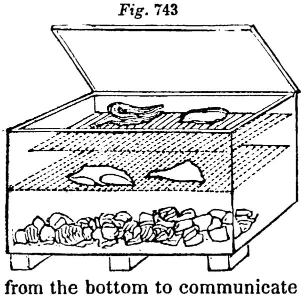


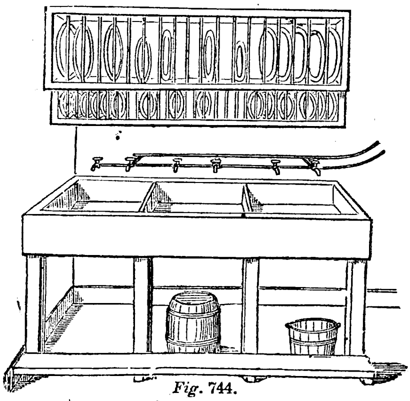
4682. *Knife trays* are made with a partition in the centre, which serves the purpose of a handle.

4683. *Safes* are necessary to keep meat in, whether raw or cooked, to defend it from flies and other insects, particularly where there is no regular larder. They are portable cupboards, generally of wood, with the panels of the doors and sides filled with some perforated substance to let the air in properly, but so as to preclude the entrance of flies, &c. The most usual material for this purpose is what is called *safe* canvass. Iron wire is also employed, not being liable to be gnawed by mice and rats; but this requires to be kept well painted in oil, otherwise it will soon decay by rust. The common wire cloth is woven by a machine; a stronger wire is woven by hand, but is more expensive, though more durable. Perforated zinc plates are likewise employed for this purpose; and safes made altogether of zinc are constructed for exportation to tropical climates, where the white ants frequently destroy those of wood. The comparative prices are: a small safe, with canvass, 15*s.*; one ditto, with iron wire, 18*s.*; one ditto, with zinc plates, 21*s.*; and one with wire woven by hand, 25*s.*

4684. *An ice cooler* (*fig.* 743) is a useful addition to a larder for keeping meat, fish, butter, or other things very cool. It consists of a strong chest, having the sides of thick wood, or, what is better, of two thicknesses of wood, with a space of an inch between, which may be filled with charcoal dust, to make it a good non-conductor of heat. A quantity of ice must be laid upon the bottom; and a little above this there should be an iron grating to lay the meat and other articles upon. If required, there may be two of these gratings, sufficiently apart to admit of joints, &c., lying on the lower one, and there should also be a contrivance for lifting out these gratings; a wooden cover shuts over the whole. To carry off the water that forms from the melting of the ice, there must be a waste-pipe from the bottom to communicate with the drain. This chest should not stand immediately upon the floor, but should be supported upon several small pieces of wood, that the heat may not be communicated from the floor to the bottom of the ice cooler. This will serve for vegetables as well as amimal food.

Fig. 743



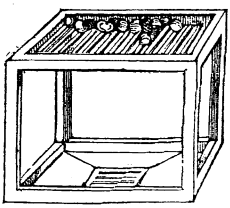


4685. *Fig.* 744 represents a *sink* in the scullery, with pipes and cocks for hot and cold water, with a plate-rack over it: the tubs for hog wash are placed beneath.

Fig. 744.

4686. *Fig.* 745 is a *potato drainer*, to lay potatoes on to drain after they are washed. A grating below carries away the wet.

Fig. 745.



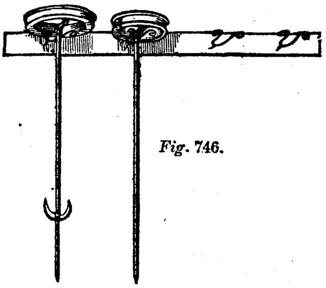


Fig. 746.

4687. *Fig.* 746 is a *spit-rack* to hang spits upon after they are cleaned, and are ready for use.

CHAPTER V.

EXAMPLES OF VARIOUS KITCHEN FIRE-PLACES.

4688. It may be useful, in illustration of what we have said, to give some examples of kitchen fire-places which have been fitted up and found convenient.

4689. *Fig.* 747 represents one of the smallest size ranges, the fire-bars one foot six

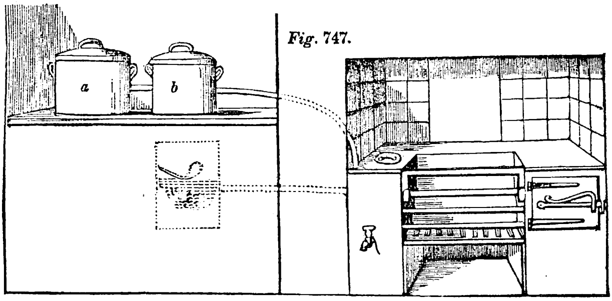

Fig. 747.

inches in length. On one side is an oven heated by the fire; and on the other side is a boiler, also extending behind the back of the fire, with a cock to draw off the water. The boiler may either be filled every day by the circular cover on the top, or, what is better, it may be fed by a cistern and a ball-cock, as represented by the dotted lines. This boiler may likewise furnish steam to the two tin steam vessels, *a* and *b*, placed over the cistern. The pipe which supplies the steam is indicated by the curved dotted line. The throat of this chimney should be made narrow, and the inside may be lined with Dutch or white delft-ware tiles, which gives a very clean and neat appearance.

4690. *Fig.* 748 is another arrangement on a larger scale. In the kitchen chimney

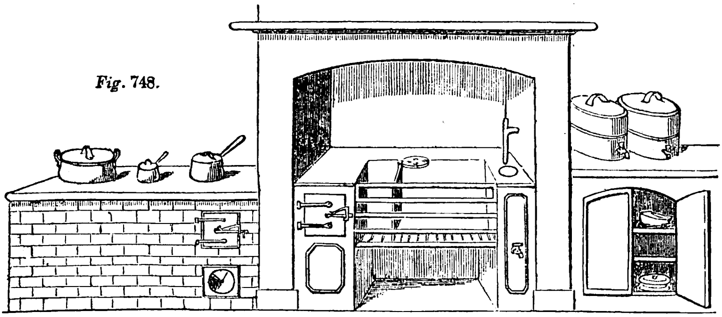

Fig. 748.

there is the usual range, with an oven on one side and a boiler on the other. Connected with the last, on the right, is a set of steamers, and a hot closet beneath heated by the steam. On the left of the chimney there is a hot plate, with a separate fire-place set in brick-work; and this is, in general, the best way of fitting up the hot plate, since the bricks confine the heat, and the kitchen is not made so warm as when the whole is of iron. The hot plate may be placed in any part of the kitchen where there is a possibility of having a flue.

4691. In some places they have tried to do away with the use of an open fire and kitchen range, and to depend upon hot plates, baking ovens, steam, and other modes lately introduced; but however economical these arrangements may be in point of fuel, and however well adapted to particular cases, we cannot recommend the banishment of the kitchen range, when we consider the frequent change of servants, their general want of intelligence, and the great attention and care which these new modes demand, though excellent in principle.

4692. When there is no flue to carry off the air heated by the hot plate and the steamers, the hot air comes into the kitchen, causing the place to be uncomfortably

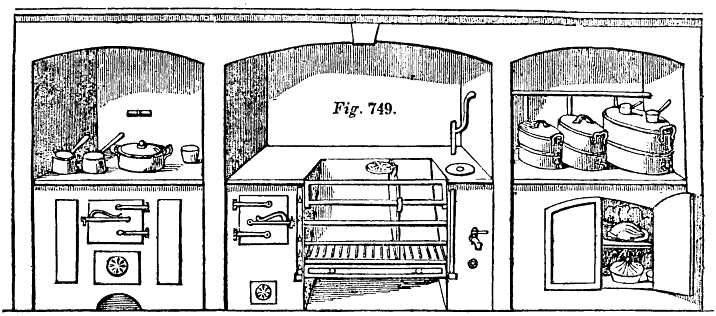

Fig. 749.

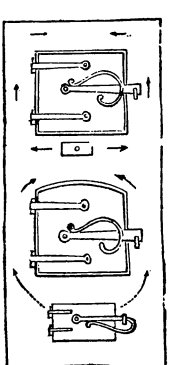

Fig 750.

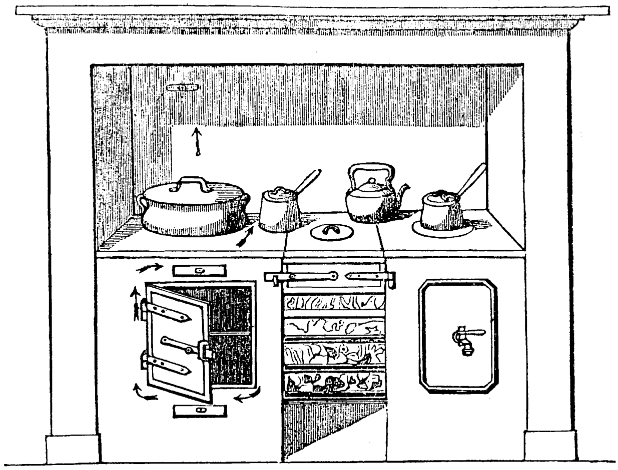
warm; to prevent this effect, it is best, if possible, to place these parts of the apparatus in recesses in the wall like chimneys, the flues of which may either go to the top of the house, or join the chimney flue. This will add much to the healthiness of the kitchen; but the possibility of effecting this improvement must depend upon the locality; and a good light in these recesses is necessary. *Fig.* 749 represents such an arrangement, where the middle recess contains the range with its boiler and oven; in another recess is a hot plate; and in the third a set of steamers, with a hot closet beneath, also heated by steam.

4693. *Fig.* 750 *represents an oven and a hot closet* made of cast iron as a separate article of furniture, to be put up in any place where there is access to a flue. The oven may, if required, be a roaster or roasting oven; and it is heated by its own separate fire, which, after circulating all round the oven, goes round the hot closet in the direction of the arrows. Such an apparatus may often be useful, in addition to others of a similar kind. Proper places must be made for sweeping out the flues. This may be put into a recess in the brick wall, or project into the apartment with four or nine-inch brick-work on the sides, which will be proper to confine the heat.

4694. The following kitchen fire-places are upon the principle of having a hot plate immediately over the fire: *Fig.* 751 is a kitchen fire-place, which, we believe, first ap-

Fig. 751.

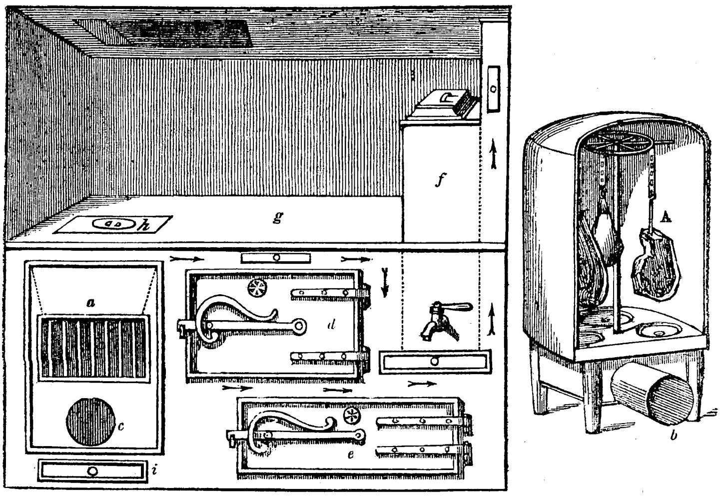


peared as the invention of the Marquis de Chabannes, about forty years ago. Here the fire in the range, instead of being open at top in the usual way, is covered by a plate of cast iron, and the smoke is made to pass into a flue behind the back of the chimney. By this mode the soot is prevented from falling upon the various vessels placed on the hot plate; and when the inside of the chimney is lined with white glazed tiles, it has a very neat and clean appearance. Immediately below the hot plate, and above the bars of the grate, there is a narrow door for throwing coals on the fire, and just over the fire there is a circular aperture, generally covered with an iron plate; but when this cover is left off, the aperture serves to cause anything to boil quick when placed over it. On the right of the range is a boiler, and on the left an oven; but the latter was only of the ordinary kind, and not furnished with a current of hot air like the Rumford roaster; it could therefore only bake, but not roast. We cannot recommend this arrangement, and present it rather to show from what some of the later kitchen fire-places have been derived.

Of late several kitchen fire-places have appeared, so constructed that the whole is connected together, requiring merely to be placed in the chimney, with very little setting by the bricklayer. We shall describe a few of them; but must observe, that though they have some advantage in point of neatness and compactness, yet the latter quality is productive of this inconvenience, that when any part wears out, or is out of order, the whole machinery is probably stopped; and that the difficulty of repairing is always great, often, from the locality, even impracticable. On account of repairs, it is best to have the several parts of kitchen apparatus as much as possible independent of each other. We must likewise state, in justice to our readers, that in all their descriptions of these kitchen fire-places, the ironmongers represent them as capable of doing much more than in practice they can perform with that convenience essential to the cook.

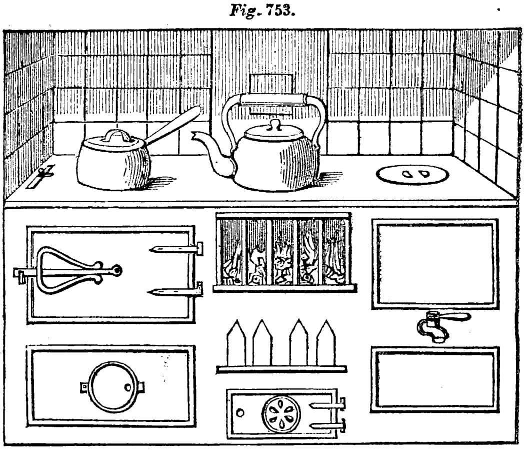
4695. *Brown's cooking apparatus* (*fig.* 752) is a late invention of this kind; and the roasting part has at least novelty and ingenuity to recommend it. The meat to be roasted is hung in a niche formed of a screen of tin, shown at A, and placed before the vertical bars of the fire, which are seen at *a*. The tube, *b*, of the screen is inserted into the circular aperture, *c*, below the fire; the meat is turned round by the current of air that feeds the fire; for when the fire burns, and is wanted for roasting, air enters by this aperture to supply it; but before it reaches the fire, it must pass through the tube *b*, and in doing so it acts upon a vertical fan wheel placed below the dripping pan, and sets it in motion; the axis of this fan acts upon another wheel, which has its axis upright, rising into the screen, and carrying upon its upper end a circular disk. To the circumference of this disk are suspended one or more pieces of meat, which, of course, revolve with the axis, and present their different sides to the fire in succession; and this motion must continue as long as the fire burns, because so long will a current of air enter by the tube, and act upon the fan wheel; the motion will be faster or slower, as the fire burns more or less briskly. The heat of the fire coming through between the upright bars, together with what is sent off by the heated iron front, and the strong reflection

Fig. 752.



from the inside of the screen, is said to be sufficient to roast the meat. Over the fire is a hot plate; *d* is an oven; *e* is a hot closet; *f* is a boiler, and *h* is a broiling place in the hot plate, all heated by the same fire. The flame and smoke pass entirely under the hot plate, and, of course, over the top of the oven in the direction of the arrows; part of it also passes beneath the oven; and they then turn downward and go under the bottom of the boiler, which extends down as far as the dotted lines. The smoke then ascends by the side of the boiler, *f*, as shown by the arrows, and finally passes into the chimney. The hot closet, *e*, is warmed by the hot smoke passing over it. When broiling and not roasting is required, the fire-door must be shut, and also the aperture *c*, while the aperture *h* is opened. The air to supply the fire then comes in through *h*, and, of course draws downward; over this aperture the gridiron for broiling is placed; or, if quick boiling be wanted, the kettle is put over it. Ordinary boiling and stewing are performed upon the hot plate; and it would be easy to add a steam apparatus. The throat of the chimney is closed, except a square aperture to let off occasional vapours; and this may be shut, when required, by a sliding plate. When neither roasting nor broiling is going on, the aperture *c* is closed, and a drawer, *i*, is pulled out a little; this supplies air to the fire, and will likewise serve to regulate the draught, so that the fire may be kept for a long time just a-light. Any kind of coal may be burned; but the best fuel is a mixture of anthracite and common coal.

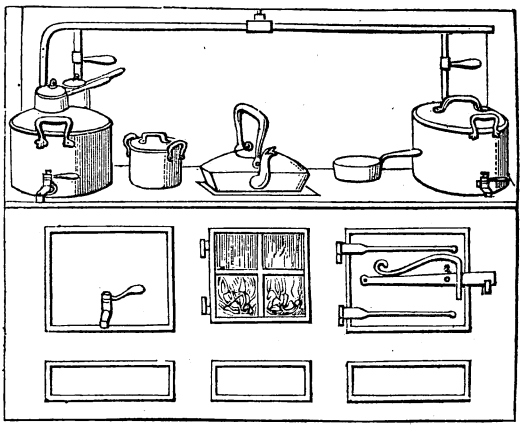
Fig. 753.



4696. *Wright's kitchen range* (*fig.* 753) has the fire enclosed by a door filled by plates of mica, improperly called talc. The heat comes through the mica, sufficient, *it is said*, to roast meat placed in a tin niche on a large Dutch oven, with a spring jack attached. The fire also heats a hot plate placed over it, having an aperture in the centre for boiling a square tea-kettle, or for broiling; on one side is an oven, and on the other a boiler, both heated by the flame and smoke passing round them in flues constructed in the iron-work, while meat and vegetables may be steamed in vessels supplied with steam from the boiler. A pipe may likewise convey steam to any other part of the kitchen for a similar purpose.

4697. *Figure* 754 is *Brown* and *Green's* kitchen fire-place, nearly on the principle of the last; but when roasting is to be performed, an iron plate is slid down before the fire-bars; and though at first sight it might not appear to be the case, the heat given out is greater than when the fire is exposed to view; for then the draught of air through the fire carries much of the heat up the flue; but when the aperture of the fire is closed, the fire being fed with air only from the registered opening below, it burns with great fierceness against the iron plate, which becomes red hot; and it is by the radiant heat thrown off by this that the roasting is effected, the meat being suspended in a tin niche screen Below the hot plate, on the right, is an oven, and on the left is a boiler, which supplies a set of steamers in another part of the kitchen.

Fig. 754.



4698. *Several other ranges, nearly similar*, are manufactured by various ironmongers, but not so different as to demand a separate description. It must be observed that we decline giving any opinion on the efficacy of these ranges, in which the fire is covered by a hot plate, as they require more trial than we have been able to give them. But it is very evident that they are very expensive in the first instance, and require the cook to be taught how to use them; they are also very apt to be out of order, the narrow flues requiring to be frequently cleaned out. The economy of fuel which they promise is, perhaps, not a set-off against these inconveniences; nevertheless, they have a very attractive appearance, and in some situations may be very useful with those who will take the trouble of managing them properly. For common English cooking and English servants, we can scarcely venture to recommend dispensing with a good open fire. Some of the best kitchens are to be seen in the London club-houses, which have been fitted up with all the modern improvements; and a visit to them will amply repay those who have taste and discernment enough to perceive the advantage of studying and improving this part of our domestic economy. In some of these steam is very successfully applied in a variety of ways; and the facility with which the culinary art is carried on is deserving of attention.

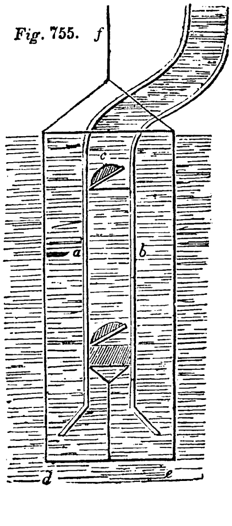
CHAPTER VI.

PUMPS, AND LIST OF FURNITURE.

4699. Pumps being machines in common use in many establishments, it is proper that their construction should be understood; and we proceed to explain their general principles. The different kinds may be reduced to three, the lifting, sucking, and forcing pump.

4700. *The lifting pump* (*fig.* 755) is the simplest, though not so frequently used in domestic economy for raising water as the common, or sucking pump. Its employment is chiefly restricted to such places as mines, where water is required to be raised in great quantities, and from a great depth. A cylinder, *a b*, descends into the water to be raised, and has a valve placed at *c*, opening upward. A piston, having a valve in it also, opening upward, is moveable upward and downward in the cylinder by means of iron rods, *d, e, f*. When the piston is pushed down in the water, its valve opens, and when it is raised the valve shuts, and as the water above it cannot descend, the piston lifts it as far as the length of its stroke, causing it, at the same time, to lift the valve *c*; on the piston descending again, the water that has been raised above *c* remains there, that valve falling down and preventing its descent. The same effect follows every stroke of the piston, more and more water getting above both valves,

Fig. 755.



which, by shutting each time, prevents its descent again. By a repetition of this action, water is at length lifted up as high as it is required; but it is to be observed that, as the piston has to support the whole weight of the water above it when the valve *c* opens, great power is necessary in raising water from considerable depths.

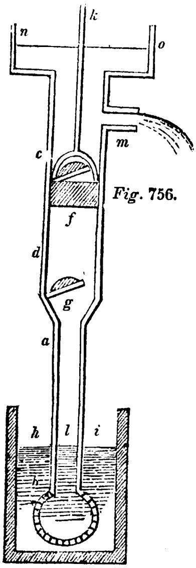


Fig. 756.

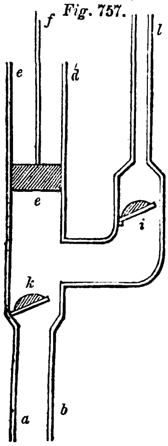
4701. *In the sucking pump* (*fig.* 756) the raising of water is assisted by the pressure of the atmosphere. It is known that this pressure is equal to the weight of a column of water about thirty-two feet in height, according to the height of the barometer; water can, therefore, be raised so high, but not higher, by taking advantage of this pressure. To effect this, a tube or cylinder is provided, thirty-two feet in length, *a*, *b*, called the suction pipe, which is plunged into the water to be raised, having some contrivance at the bottom to permit the water to enter, but keep back pebbles and dirt, and a valve opening upward at the top, *g*; on this is placed another short cylinder, *c d*, but of larger diameter; this has a piston, *f*, working in it upward and downward by means of the rod, *k*; when this piston, which must fit very exactly into the cylinder in which it works, is pushed down, its valve will rise, the air beneath acting in the same manner as the water in the lifting pump, and when the piston is raised, its valve will close, and it will lift up the air that is above it; but by this means a portion of air has been withdrawn from the space between the two valves, and the air in the suction pipe, by its elasticity, hastens to supply the vacuum thus formed, and opens the lower valve, *g*. Through the extraction of a portion of air by the upward motion of the piston, the whole of the air beneath it is in some degree rarefied, and consequently the pressure upon the water at *l*, in the inside of the suction pipe, is not now so great as before, and is less than that upon the surface of the water at *h* and *i*, on the outside, which has the undiminished pressure of the atmosphere. The consequence of this unequal pressure on the water within and without the suction pipe is, that water is forced into the interior of the latter, and rises at each stroke of the piston until it reaches it. On the next action of the piston, it works in the water, and the effect is the same as was described in the lifting pump, the piston lifting at each stroke the water above it; but as the piston is made to work near the top, and near the place of delivery, this weight is very little, the pressure of the atmosphere now always keeping up the water as high as the piston. The water so raised now runs out by a short pipe at the side, *m*. To provide for the constancy of this stream, a small reservoir, *n o*, is formed upon the top of the pump. It is scarcely necessary to observe that the piston rod is usually moved up and down by a lever called the pump handle.

4702. *The operation of the common forcing pump* is the following: *a b*, *fig.* 757, is a suction pipe descending into a well, tank, &c., containing water, and having in it a valve, *k*, opening upward. The piston, or working barrel, *c d*, *fig.* 757, contains, *e*, a solid piston without any valve, moved up and down by the rod *f*. We will suppose that, at first, all these are full of air only. When the piston, *e*, descends, it will condense the air below it, which will cause the valve *k* to shut; but the condensed air will find its way out through the valve *i*, placed in the branching pipe; as soon as the piston rises, the spring of the air in the suction pipe, *a b*, will force up through the valve *k*, to supply the partial vacuum between the piston and this valve, the air being now rarefied in that place. When the piston next descends, the same effect will be repeated, and more air will be driven out through the valve *i*. But the result of rarefying the air in the suction and piston barrels at each stroke of the piston will be, that the pressure of the atmosphere on the surface of the water outside the suction pipe will force the water up into it until it rises as high as the piston, in the same way as in the sucking pump; when this happens, on the next stroke of the piston downward it will force the water through the valve *i*, in the same manner as it before did the air, and by using sufficient force, and proportioning the size of the barrels and the pipes properly, the water may be forced as high as is desired through the pipe *l*.

Fig. 757.



4703. *A better construction of a pump*, to answer the same purpose as the last, is in this manner: *a b*, *fig.* 758, is the suction pipe, with its valve, *e*, and *c d* the branch pipe, with its valve, *f*. The top of the working barrel, *g h*, is closed, but allowing the piston rod to work through it in a collar of leather, so as to be air-tight. The piston here has a valve in it opening upward, as in the sucking pump. It is obvious that this piston with its valve, and the pipe *a b*, with its valve, *e*, is really a sucking pump, and acts as such, raising the water by the pressure of the atmosphere till it reaches the piston ; but when this happens, and the piston forces down through the water so raised, raising up the piston will cause it to act as in the lifting pump ; and since the water thus lifted cannot get out through the top of the working barrel, *g h*, this being closed, it will be forced out through the branch pipe, *c d*, and its valve, *f*, and afterward through the ascending pipe, *i*. This pump is, therefore, a combination of the sucking and lifting pumps ; and it is easy to conceive that a sucking pump may be converted into this machine with little difficulty. This construction has several advantages over the last. The greatest force on the piston rod is exerted in pulling it upward instead of forcing it downward, which is less apt to bend them.

Fig. 758.

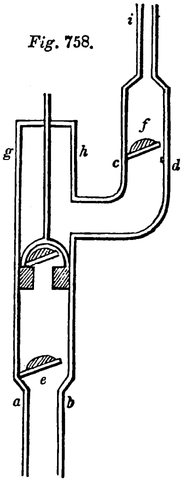


Fig. 759.

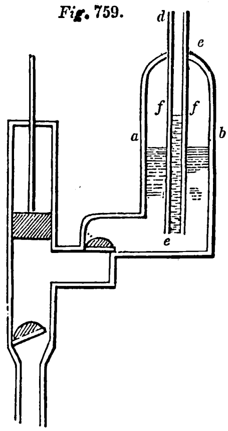
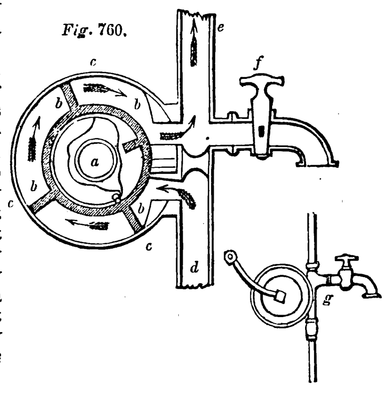


4704. *To obtain a continued stream of water*, instead of its coming in starts, an air vessel (*a b*, *fig.* 759) may be put on the branch pipe of *fig.* 757 or 758. This vessel may be of any form, but is closed at the top, and has a pipe, *d e*, descending into it. The water forced up into the branch pipe cannot escape at top, but is forced out through the small pipe, *d e*, the lower end of which is open ; and the air in the space *f f* being thus condensed there, will act constantly by its spring upon the surface of the water in *a b*, and force it out through the pipe *d e* in a constant stream, as in the fire-engine.

4705. *Siebe's rotatory pump* is found very convenient either for raising water from a tank or well, or for forcing it up to any height. This pump (*fig.* 760) operates by the rotation of a roller on its axis, *a*, having paddles or pistons, *b b b b*, by which, when the roller is turned, a vacuum is produced within the barrel, *c c c*. In consequence of this vacuum, the water flows up the rising break, *d*, into the barrel ; and as the paddles go round they force it into an opening, which conducts it wherever it may be wanted, and by that means produces a continual stream. By having an ascending tube, *e*, the water may be forced to any height ; and, by having a horizontal tube with a cock, *f*, it may be let out at pleasure, as in a common pump. By having several pipes branching from *e*, as many cisterns or reservoirs may be supplied. *g* is the external appearance of the pump.

Fig. 760.



LIST OF THE FURNITURE OF THE KITCHEN, AND OTHER OFFICES CONNECTED WITH IT.

Tables.
Chairs and stools.
Dressers.
Plate-racks.
Range, fender, and fire-irons.
Jacks for roasting.
Spits, stays, and skewers.
Bird-spits.
Meat-screen.
Sauce-pans and boilers.
Stew-pans.
Sauté-pans.
Braising-pans.
Frying-pans.
Soup-pots.
Jugging-pots.
Omelet-pans.
Patty-pans.
Digesters.
Gridirons.
Apple-roasters.

Argyles for gravies.
Steamers for ditto.
Basting-ladles.
Soup ditto.
Marrow-scoops.
Spoons of various kinds.
Beef-forks.
Cheese-toasters.
Cheese-trays.
Cheese-knives.
Bread-baskets.
Knife ditto.
Knife-boxes.
Plate-baskets lined with tin.
Bread-pans.
Cleavers.
Bone-saws.
Meat-choppers.
Hammers and other tools.
Hatchets.
Meat-knives.
Paste-cutters.
Oyster-knives.
Fish ditto.
Cucumber-slicers.
Carrot and turnip scoops.
Lobster-crackers.
Steak-beaters.
Steak-tongs.
Cooks' knives.
Cooks' scissors.
Bread-graters.
Beef ditto.
Nutmeg ditto.
Salt-strainers.
Larding-pins.
Rolling-pins.
Nut-crackers.
Lemon-squeezers.
Trenchers.
Butter-prints.
Jelly and blanc-mange moulds.
Baking-pans for bread.
Dutch and other ovens.
Iron and brass footmen.
Iron-stands.
Colanders.
Egg-coolers.
Egg-ladles.
Funnels.
Salt-boxes.
Flour and oatmeal tubs.
Flour-boxes.
Flour-dredgers.
Pepper-boxes.
Spice ditto.
Toast-racks.
Butter-forcers.
Venison-dishes.
Hash-dishes.
Dishes of various kinds.
Water-plates.
Wire meat-covers.
Coffee-pots.
Coffee-biggins.
Coffee-filterers.
Coffee-roasters.
Coffee-mills.
Sugar-canisters.
Sugar-nippers.
Sugar-dredgers.
Plate-warmers.
Sinks.
Water-filterers.
Filtering-stone brushes.
Salad forks and spoons.
Candlesticks, with snuffers and extinguishers.
Lamps, various.
Candle-boxes.
Lanterns.
Tinder-boxes.
Oil-bottles and cans.
Oil-filters.
Oil-cisterns.
Wire servants' lanterns.
Rushlight-shades.
Housemaids' gloves and leathers.
Emery, sand and glass paper.
Emery-box.
Rottenstone.
Hearthstone.
Bath bricks.
Flanders ditto.
Pipe-clay.
Masons' dust.
Silver and house sand.
Pumice.
Dust-pans, tin or iron.
Cinder and coal shovels.
Coal-scuttles, copper, iron, japanned, and wood.
Housemaids' slop-pails, tin and wood.
Cinder-pails.
Cinder-sieves.
Pumps.
Wash-hand basin.
Soap-dishes.
Soap-bowls.
Large elm bowl for washing China.
Dust-baskets.
Servants' scouring-mats.
Chafing-dishes.
Bellows.
Standing and folding steps.
Towel-horses.
Mouse, beetle, and rat traps.
Door-mats.
Warming-pans.
Stomach-warmers.
Pestle and mortars.
Plate-powders.
Plate-brushes.
Buckle and jewel ditto.
Plate-leathers.
Mahogany butler's trays for sandwiches, &c.
Stands for ditto.
Baized baskets for silver.
Decanter and cruet brushes.
Indian straw table-mats.
Punch ladles and strainers.
Plated decanter corks and labels.
India-rubber stoppers.
Crumb-brushes.
Wine funnels and strainers.
Leather aprons.
Leather and wood knife-boards.
Knife sharpeners.
Corkscrews.
Wine-coolers.
Japanned trays of various kinds.
Clothes-beaters.
Decanter-drainers.
Decanter-stands.
Boot-jacks.
Shoe-brushes.
Hair-brooms.
Carpet ditto, in whisk, hair, or whalebone.
Hearth-brooms.
Baluster ditto.
Furniture brushes.
Furniture brushes loaded.
Feather-brooms for pictures, &c.
Turk's head ditto.
Dry rubbers for floors.
Scrubbing-brushes.
Area and yard ditto.
Stove ditto.
Egg-beaters.
Packthread and twine
Paper.
Packthread boxes.
Packing-mats.
Drinking-horns.
Glove hands and stretchers.
Trimming-tray, &c., for lamps.
Bottling-machines.
Cork-drivers.
Wine-baskets.
Wine-casks.
Beer-funnels.
Beer-tilts.
Beer-stands.
Spigots and faucets.
Sawdust-shovels.
Mallets.
Clothes flaskets and baskets.
Clothes-horses.
Hair and white clothes-lines.
Washing and rinsing tubs and troughs.
Washing-benches.
Washing-trays.
Boards to stand on.
Copper-sticks.
Wash-hand bowls.
Draining-baskets.
Clothes-props.
Clothes-pegs.
Starch-sieves and whisks
Laundry-jacks.
Mangles.
Inkstands.
Horn and willow shaving for grates.
Bed-wrenches.
Bells and bell-pulls.
Table-bells.
Cash-boxes.
Tea equipages.
Napkin-presses.
White and black hair, lawn, and tammy sieves.
Drying, wire, and fruit ditto.
Wooden spoons of various sizes.
Paste-brushes.
Jelly bags and stands.
Stills.
Paste rollers and jaggers.
Biscuit-dockers.
Vegetable-drainers.
Vegetable-tubs.
Pickling tubs and trays.
Chopping boards and blocks.
Covers for dishes.
Chopping-knives.

BOOK XII.

PRACTICAL HOUSEHOLD DETAILS CONNECTED WITH COOKERY.

CHAPTER I.

MARKETING.

4706. The leading facts relative to each of the animals and vegetables used as food have been stated in Book VIII., and to that the reader is referred. The directions contained in the present chapter are intended more particularly for cooks and persons employed to market; and they ought not to be considered as unimportant, since novices in marketing and cooking must seek instruction in aid of inexperience.

Sect. I.—RULES FOR MARKETING.

4707. *In marketing, the first rule* is to purchase chiefly from known and respectable tradespeople, who are likely to go themselves to the best markets, and who have to support the character of their shops.

4708. *The second rule* to be observed is that of not purchasing inferior articles under the idea of being economical.

4709. *A bargain* is seldom a prize ; and this is especially the case in regard to butcher's meat.

4710. *The best meat and the prime parts* are unquestionably the cheapest in the end, although the first cost may be the greatest. In coarse and inferior joints there is always too great a proportion of gristle, bone, and hard meat to render them truly economic; these may serve as the basis of soups, gravies, or stews; but for roasting or boiling they are wasteful.

4711. *The criteria of bad meat*, by which must be understood meat that has been too long killed, or meat from animals killed in a state of disease, ought to be well known by those who market. no less than the value and economy of the different parts and joints.

Subsect. 1.—*Joints and Parts of Butcher's Meat enumerated.*

4712. *The bullock* is divided in the shambles as marked in *fig.* 761. The joints are not here given in the order in which they are estimated as prime or as inferior parts :

1. Sirloin; 2. Rump; 3. Edgebone; 4. Buttock; 5. Mouse buttock; 6. Veiny parts; 7. Thick flank; 8. Thin flank; 9. Leg; 10. Fore ribs; 11. Middle ribs; 12. Chuck ribs; 13. Leg of mutton piece; 14. Brisket; 15. Clod; 16. Sticking piece; 17. Shin; 18. Cheek.

Besides these parts, there are the tongue, palate, sweetbreads, kidneys, skirts, and tripe.

A baron of beef, now an obsolete joint, consisted of the two sirloins undivided.

Fig. 761.

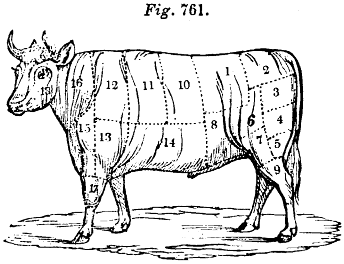


Fig. 762.

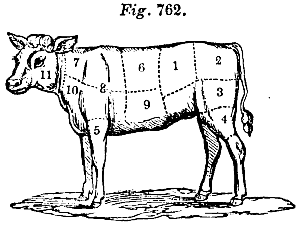

4713. *The calf* (see *fig.* 762) is divided into, 1. Loin (kidney end); 2. Loin (chump end); 3. Fillet; 4. Hind knuckle; 5. Fore knuckle; 6. Neck (best end); 7. Scrag; 8. Blade bone; 9. Breast (best end); 10. Brisket; 11. Head. To these joints must be added the *Pluck*, which includes the liver, lights, heart; sweetbreads, of which one is called the throat sweetbread, and is the largest of the two, the other the windpipe sweetbread.

4714. *Sheep, fig.* 763.—1. Leg; 2. Loin (best end); 3. Chump end of the loin; 4. Neck (best end); 5. Scrag; 6. Shoulder; 7. Breast. The loins not separated form what is termed the saddle of mutton.

4715. *The lamb* is usually divided into four parts, called the fore and hind quarters. Each fore quarter consists of a shoulder, with part of the neck and breast. Each hind quarter consists of a leg and loin. By the target of lamb is meant the ribs, when the shoulder is separated from them.

The lamb's head is generally sold with the *appurtenances*; in which last are comprehended the *liver, lights, heart, suet,* and *melts*.

The fry of the lamb contains *lambstones, sweetbreads*, and skirts, with a part of the liver.

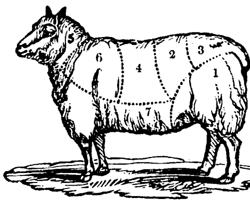

Fig. 764.

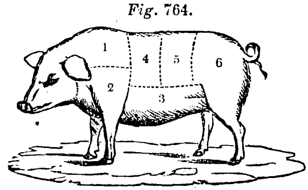

4716. *The hog*, see *fig.* 764.—1. The sparerib; 2. Hands; 3. Spring; 4. Fore loin; 5. Hind loin; 6. The leg. The head and the haslet must also be mentioned; the latter includes the liver, kidneys, and skirts. The chitterlins and guts are cleaned for sausages.

A porker is a small pig fed for eating fresh, and not for curing.

Of a bacon pig, the legs are reserved for curing, and when cured are called *hams;* when the shoulder blade and bones are separated from the meat and cured, it is called *bacon.* The bones, with part of the meat left on them, are divided into spareribs, griskins, and chines.

SUBSECT. 2.—*Choice of Meat, Fish, and Poultry.*

4717. *Beef.*—The grain of *ox beef*, when good, is loose, the meat red, and the fat inclining to yellow. *Cow beef*, on the contrary, has a closer grain, a whiter fat, but meat scarcely as red as that of ox beef. *Inferior beef*, which is meat obtained from ill-fed animals, or from those which had become too old for food, may be known by a hard, skinny fat, a dark-red lean, and, in old animals, a line of a horny texture running through the meat of the ribs. When meat pressed by the finger rises up quickly, it may be considered as that of an animal which was in its prime; when the dent made by pressure returns slowly, or remains visible, the animal had probably passed its prime, and the meat, consequently, must be of inferior quality.

4718. *Veal* should be delicately white, though it is often juicy and well-flavoured when rather dark in colour. Butchers, it is said, bleed calves purposely before killing them, with a view to make the flesh white; but this also makes it dry and flavourless. On examining the loin, if the fat enveloping the kidney be white and firm-looking, the meat will probably be prime and recently killed. Veal will not keep as long as an older meat, especially in hot or damp weather; when going, the fat becomes soft and moist, the meat flabby and spotted, and somewhat porous, like sponge. Large, overgrown veal is inferior to small, delicate, yet fat veal. The fillet of a cow calf is known by the udder attached to it, and by the softness of the skin; it is preferable to the veal of a bull calf.

4719. *Mutton.*—The meat should be firm and close in grain, and red in colour, the fat white and firm. Mutton is in its prime when the sheep is about five years old, though it is often killed much younger. If too young, the flesh feels tender when pinched; if too old, on being pinched it wrinkles up, and so remains. In young mutton, the fat readily separates; in old, it is held together by strings of skin.

In sheep diseased of the rot, the flesh is very pale-coloured, the fat inclining to yellow, the meat appears loose from the bone, and, if squeezed, drops of water ooze out from the grains; after cooking, the meat drops clean away from the bones.

Wether mutton is preferred to that of the *ewe;* it may be known by the lump of fat on the inside of the thigh.

4720. *Lamb.*—This meat will not keep long after it is killed. The large vein in the neck is bluish in colour when the fore quarter is fresh, green when becoming stale. In the hind quarter, if not recently killed, the fat of the kidney will have a slight smell, and the knuckle will have lost its firmness.

4721. *Pork.*—When good, the rind is thin, smooth, and cool to the touch; when changing, from being too long killed, it becomes flaccid and clammy. Enlarged glands, called kernels, in the fat, are marks of an ill-fed or diseased pig.

4722. *Bacon* should have a thin rind, and the fat should be firm and tinged red by the curing; the flesh should be of a clear red, without intermixture of yellow, and it should firmly adhere to the bone. To judge of the state of a ham, plunge a knife into it to the bone; on drawing it back, if particles of meat adhere to it, or if the smell is disagreeable, the curing has not been effectual, and the ham is not good; it should, in such a state, be immediately cooked. In buying a ham, a short thick one is to be preferred to one long and thin. Of English hams, Yorkshire, Westmoreland, and Hampshire are most esteemed; of foreign, the Westphalia.

4723. *Venison.*—When good, the fat is clear, bright, and of considerable thickness. To know when it is necessary to cook it, a knife must be plunged into the haunch; and from the smell the cook must determine on dressing or keeping it.

4724. *In choosing poultry*, the age of the bird is the chief point to be attended to.

4725. An old turkey has rough and reddish legs; a young one smooth and black. Fresh killed, the eyes are full and clear, and the feet moist. When it has been kept too long, the parts about the vent begin to wear a greenish, discoloured appearance.

4726. *Common domestic fowls*, when young, have the legs and combs smooth; when old, they are rough, and on the breast long hairs are found instead of feathers. Fowls and chickens should be plump on the breast, fat on the back, and white-legged.

4727. *Geese.*—The bills and feet are red when old, yellow when young. Fresh killed, the feet are pliable, stiff when too long kept. Geese are called green while they are only two or three months old.

4728. *Ducks.*—Choose them with supple feet, and hard, plump breasts. Tame ducks have yellow feet, wild ones red.

4729. *Pigeons* are very indifferent food when they are too long kept. Suppleness of the feet show them to be young; the state of the flesh is flaccid when they are getting bad from keeping. Tame pigeons are larger than the wild.

4730. *Hares and rabbits*, when old, have the haunches thick, the ears dry and tough, and the claws blunt and rugged. *A young hare* has claws smooth and sharp, ears that easily tear, and a narrow cleft in the lip. *A leveret* is distinguished from a hare by a knob or small bone near the foot.

4731. *Partridges*, when young, have yellow legs and dark-coloured bills. Old partridges are very indifferent eating.

4732. *Woodcocks and snipes*, when old, have the feet thick and hard; when these are soft and tender, they are both young and fresh killed. When their bills become moist, and their throats muddy, they have been too long killed.

4733. *Turbot*, and all flat white fish, are rigid and firm when fresh; the under side should be of a rich cream colour. When out of season, or too long kept, this becomes a bluish white, and the flesh soft and flaccid. A clear, bright eye in fish is also a mark of being fresh and good.

4734. *Cod* is known to be fresh by the rigidity of the muscles (or flesh), the redness of the gills, and clearness of the eyes. Crimping much improves this fish.

4735. *Salmon.*—The flavour and excellence of this fish depend upon its freshness and the shortness of the time since it was caught; for no method can completely preserve the delicate flavour it has when just taken out of the water. A great deal of what is brought to London has been packed in ice, and comes from the Scotch and Irish rivers, and, though quite fresh, is not quite equal to Thames salmon. For many particulars respecting this excellent fish, see Book VII., Sect. III.

4736. *Mackerel* must be perfectly fresh, or it is a very indifferent fish; it will neither bear carriage, nor being kept many hours out of the water. The firmness of the flesh and the clearness of the eyes must be the criterion of fresh mackerel, as they are of all other fish.

4737. *Herrings* can only be eaten when very fresh, and, like mackerel, will not remain good many hours after they are caught.

4738. *Fresh-water Fish.*—The remarks as to firmness and clear, fresh eyes apply to this variety of fish, of which there are carp, trench, pike, perch, eels, &c. See Book VII., Sect. III.

4739. *Lobsters*, recently caught, have always some remains of muscular action in the claws, which may be excited by pressing the eyes with the finger; when this cannot be produced, the lobster must have been too long kept. When boiled, the tail preserves its elasticity if fresh, but loses it as soon as it becomes stale. The heaviest lobsters are the best; when light, they are watery and poor.

4740. *Crab and cray-fish* must be chosen by observations similar to those given above in the choice of lobsters. Crabs have an agreeable smell when fresh.

4741. *Prawns and shrimps*, when fresh, are firm and crisp.

4742. *Oysters.*—If fresh, the shell is firmly closed; when the shells of oysters are opened, they are dead, and unfit for food. The small-shelled oysters, the Pyfleet, Colchester, and Milford, are the finest in flavour. Larger kinds, called *rock oysters*, are generally considered only fit for stewing and sauces, though some persons prefer them.

Subsect. 3.—*Purchase of Grocery.*

4743. *In the purchase of grocery at a retail shop*, it does not appear that any advantage in price results to the housekeeper from laying in large stores at once, though the practice may, in some situations, be convenient. The retail grocer being compelled to market for his goods with ready money, and finding also great competition in his trade, is induced to put at once on his goods the lowest profit he can afford to ready money customers. To those requiring yearly or half yearly credit, he adds such a per centage as may remunerate him in the end for the slow return of his capital, and for the risk incurred of making bad debts; this additional charge is only just, and is done in every other retail business. Thence the economy, in most cases, of ready money purchasers.

4744. *In purchasing grocery from the wholesale dealer*, a family may occasionally gain some advantage in price; but to do it uniformly would not be convenient or desirable, either to the buyer or the seller. A quick consumption is desirable of the finer articles of grocery, especially those with aromatic properties, which exposure to the air dissipates. Thence family stores, which are slowly consumed, are daily impairing in quality, excepting only some few articles, which are supposed to improve by that exposure. By purchasing from the retail dealer this inconvenience is avoided. With some other articles of family consumption, besides grocery, the case is different, and of these it is best to keep a quantity in the store-room.

4745. *Tea.*—For the genuine characters of tea, under the two principal classes of Souchong and Hyson, together with those of coffee, in its division into the various kinds, and also chocolate and cocoa, we refer the reader to Book VIII. As a security against the adulteration of tea, many persons have purchased, through the means of brokers whole chests of tea; but there is a risk of the tea losing its flavour by exposure to the air when so much is purchased, and should the whole chest prove indifferent, there is no power of exchange. The tea market has, however, undergone great changes of late in consequence of the gradual opening of the tea trade; these changes are still going on, and, until the markets are more settled, little can be said on the subject of price.

As a rule, it may be here laid down, that whatever articles can be purchased in an unground state, such as coffee, rice, ginger, pepper, and spices, are better than those purchased ground, not entirely from the suspicion of buying adulterated articles, but because all these articles lose their flavour more rapidly when ground than when whole.

4746. *Sugar.*—For the full account of this we refer the reader to Book VIII., where the different kinds are described. *Loaf or refined sugar, when good,* is of a close texture, of a fine, white gloss, and simply sweet to the taste, without other flavour; when inferior, it is coarse and loose in grain, crumbles easily, is a little yellowish in colour, and its sweetness has something of the taste of moist sugar. *Moist sugar,* when good and unmixed with adulterating articles, is bright, and composed of crystallized grains. A dull-looking moist sugar is always one of an inferior and doubtful quality. Casks of moist sugar are sometimes procured, by families whose consumption of sugar is great, of the wholesale grocer, at a reduction of 2*d.* per pound. The price of sugar, as well as many other articles of grocery, is too fluctuating to be stated usefully.

4747. Of *rice,* there are several kinds in the market. East India rice is generally small in grain, and yellowish in colour; but some of it is excellent. The *Carolina* is large in grain, and perfectly white in appearance. Of rice it is rarely desirable to purchase large quantities. The larvæ of a fly sometimes infests old rice, and injures it materially. *East India* rice is generally lower in price than that of West India.

4748. *Raisins, currants, figs, French plums,* are dried fruits, which ought to be clean and dry, yet fresh in appearance. When adhering together in lumps, they cannot be regarded as good in quality, and in use would prove wasteful. For a description of the various kinds, see Book VII., Chap. IX.

The Muscadine raisins are dried in large bundles, and have a dry surface with a slight bloom upon them. They are chiefly used for dessert, and are sold at the grocers' under the term "table raisins." The jar or sun raisins are separated from the stalks when dried; and, as well as the Malaga, are chiefly in domestic use for puddings, cakes, &c.

Currants should be new when purchased for stores. They are to be bought new generally in September or October. When currants are offered at a very low price, it may be fairly suspected that they are of the last year's importation, or are of Spanish growth, and not the product of the genuine vines of Zante or Cephalonia.

4749. *Arrow-root.*—In the purchase of this article it should be observed that when very smooth and floury it may be suspected to contain some portion of the starch either of wheat or potatoes; which, although not injurious, does not possess all the valuable qualities ascribed to the genuine arrow-root, in thickening and jellying properly the liquid with which it is prepared for use. A tea-spoonful of real arrow-root will thicken a tea-cupful of hot water or milk, while double the quantity of adulterated arrow-root would be required to jelly the same quantity of liquid. The pure arrow-root is from 2*s.* 6*d.* to 3*s.* 6*d.* per lb.

4750. *Ginger* is of two kinds: the superior is called *white ginger,* the inferior *black.* (For the difference between them, see Book VII., Chap. X.)

4751. *Pepper* should not be purchased in large quantities by any one who has not a quick consumption of it, as the strength of it, especially when ground, is constantly lessened by exposure to the air.

Cayenne pepper is sometimes adulterated; see Book VII., Chap. X. *Of cloves,* such should be selected as have a strong fragrant odour, and a hot, aromatic, yet pungent taste. *Nutmegs* are chosen by weight, the heaviest being the best. *Mace,* when good, is very unctuous to the touch, flexible, and thin; it resembles the nutmeg (of which it is the outer coating) in odour and taste, but is not equally pungent. In the purchase of *cinnamon,* it is necessary to know that a spurious kind is often sold, called *cassia.* The distinctive marks between cinnamon and cassia are chiefly these: cinnamon is pliable, and breaks in long splinters; cassia is brittle, and when broken, the fracture is not splintered, but closes, and reveals two distinct coatings, the inner one of which is dark, and possesses a fragrance similar to that of the cinnamon, the outer coating being paler in colour, and utterly tasteless. Cinnamon is thin as paper, cassia thick and spongy.

4752. *Candles,* excluded from the light, and stored in a cool, yet dry place, are generally improved by a year's keeping.

Moulds are of various thicknesses; *three* to the pound are the largest usually made for domestic use; *short fours* are the next size; then follow in thickness *long fours, short sixes, middling sixes, long sixes,* and *eights.* These last are chiefly used as bedroom lights, or to carry about a house.

The dips are from four to sixteen to the pound. The moderate size of the tens or twelves are such as serve best for kitchen and pantry use, and to carry about a house where oil and lamps are not used.

Wax candles improve by keeping; and exposure to the light, which is injurious to tallow, blanches them. *Spermaceti candles* are considerably cheaper. See the different kinds of candles described in Book IV., Chap. III.

4753. *Soap* is an article better bought wholesale than retail. It improves in quality by being kept. It is seldom bought in a dry state. The dealer in soap is aware of the advantage he gains by storing it in damp places from the moisture, which adds materially to its weight. Soap, when in a proper state, should contain no more than thirty parts in a hundred of water; by nefarious management, an unfair dealer will make it to hold sixty; consequently, when the purchaser has it cut into pieces and laid on open shelves to render it dry and hard, it sustains a considerable loss in weight. For the laundry and household use there are three kinds: the *hard yellow*, the *soft*, and the *hard mottled soap*. On the subject of Soaps, see Books XIX. and XXII.

Sect. II.—Style and Management of the Table.

Subsect. 1.—*Carving.*

4754. *Carving*, in primitive as in modern times, was the office of the master of a feast. In the days of Roman refinement, carving became a distinct office in each distinguished family. In modern times the office of carver has not been unknown; and in royal establishments it has, in some instances, been hereditary. In France, skill in carving, from the description of the dishes served, is scarcely necessary; and thence the task has fallen on the principal attendants at table, a custom gradually finding its way into distinguished and fashionable circles in this country. Fifty years ago the art of carving was regarded by the most polished society in this country as the indispensable accomplishment of every lady who had to preside at the head of her table. It was a reflection upon her fitness for that post to say that she managed the carving-knife with little skill, or was ignorant of the choice parts of each dish. A different opinion has since been introduced by fashion; and the office of carving is assigned to gentlemen chiefly, on the ground that, in good society, of which right feelings should be the spirit, all trouble and inconvenience should devolve in every possible case on gentlemen rather than on ladies, who, on their part, should be disengaged, and ready to sustain and direct the conversation of the company. This order of the table is now universal; gentlemen are the carvers, except in those families already noticed, in which the carving is done at the side tables, by the principal attendants. Carving should not be considered as confined to the cutting up, according to certain rules, the different joints and dishes, but as consisting also in a judicious distribution of the same. To carve neatly is an economical as well as an agreeable art; a truth evident to those who have seen good joints of meat so hacked and cut to pieces as to afford scarcely half the supply of slices which, in the hands of skilful carvers, they would have yielded.

4755. *The carving-knife* should be of good steel, capable of having its sharp edge renewed; for unless it be sharp, to carve well would be impossible; neither should it be heavy to handle. The haft should be firmly grasped, though in carving strength is not, in many cases, so necessary as skill and a good knife, especially if all joint bones be properly dislocated by the butcher. The dish must not be too distant from the carver, or the arms will be too much extended, which will give an awkward appearance to the person, and render the task before him less easy in its accomplishment.

Subsect. 2.—*Directions for Carving.*

4756. Fish should be carved with a fish trowel, by which the flakes may be separated without being broken.

4757. *In a cod's head and shoulders*, the first piece may be taken off, *a*, *fig.* 765, in the direction of *a b*, by putting in the fish trowel at the back of the thick part of the fish; other slices may be taken off in a similar direction. A small portion of the sound should be given with each slice; it will be found lying close to the back bone, on raising the thin flap, *d*, and known by its being transparent, and of a darker colour than other parts of the fish. Almost every part of a cod's head is considered as good eating; such as the palate, tongue, and the jellied as well as the firm parts, *e e*, upon and immediately around the jaws and bones of the head. The green jelly of the eye alone is never eaten.

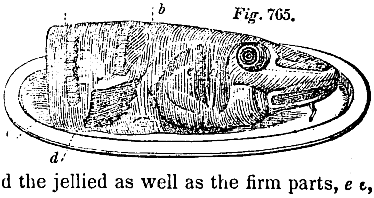

Fig. 765.

4758. *In a piece of boiled salmon*, *fig.* 766, the under part is richer and fatter than the upper and thick parts of the fish; a slice of each is usually sent on each plate. The slice from the thick part is taken in the line *a b*, and the thin slice in the direction *d c*. The skin is always sent with each slice, both of which must be cut thin.

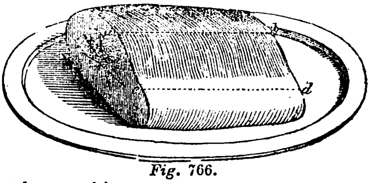

Fig. 766.

4759. *In turbot* the fish trowel is to be entered at the head, and passed along the back bone to the tail; the slices are then taken from the back bone to the fins on each side, those from the centre being considered as prime. When the upper side is thus disposed of, the back bone must be lifted up with the fork, and the under part divided in the same manner. *Of the fins*, the most prized parts of the fish, a portion is given with each slice.

4760. *Mackerel* is usually slit down the back, and the whole side taken off at once, with the exception of the part near the gills, which is generally black and ill-flavoured. The tail end of this fish is by some considered the choice part, the middle pieces by others. With the exception of cod and carp, the palate of which last-mentioned fish is esteemed as a great delicacy, the heads of fish are seldom liked. The roe of the male mackerel is soft; that of the female hard and full of eggs.

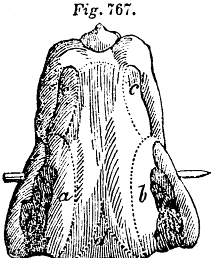
4761. *Eels* are cut into pieces through the bone, the thickest pieces of which are considered as the best.

4762. Of the *lobster* the tail is thought to be the prime part; the claws rank next to it.

4763. *Carving poultry and game* requires more practice and skill than any other dishes which are brought to table.

Fowls, either roasted or boiled, whichever way they are dressed, are cut up in the same manner. The fork (*two-pronged*) is fixed firmly into the breast, on each side of which a cut is made the whole length of the fowl, and parallel with the legs and wings. The wings are taken off in the direction *a* and *b*, *fig.* 767, by dividing the joint with the knife, and drawing it away with the fork. After cutting the ligaments at the joint of the leg, *c*, the bone may be easily twisted out of the socket, and removed from the body of the fowl. The wings and legs being thus separated from the rest of the fowl, the knife must then be entered at the breast, in the direction *d*, by which the merrythought may be displaced, after the knife has been slipped under it, and the bone lifted up, and pressed backward towards the dish. The collar-bones, *e e*, lie on each side of the merrythought, and must also be lifted up by the knife at the broad end, and forced towards the breast bone till the part breaks off to which they are fastened. The breast is cut off by cutting through the ribs on both sides. The back bone is then turned upward, and the knife passed firmly across it near the middle, the fork being, at the same time, employed in raising up the lower end towards the knife, and thus dislocating the back almost in the centre. The lower end of the back is then turned from the carver, that the bones on each side may be taken off; the exact place in which these side bones are joined to the vertebræ will be easily found by the point of the knife. The prime parts of a fowl are the wings, breast, and merrythought. The legs, except of young fowls, are considered as coarse. The thigh part, when separated from the drumstick, is sometimes preferred by those who consider the whiter meat of the fowl as insipid.

Fig. 767.



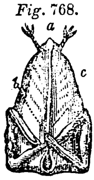
4764. *Ducks* are cut up like fowls, and have the same prime parts. The wing and leg of *ducklings* are sometimes taken off without being separated, if both together do not form too large a portion for one serving.

4765. *Turkey and goose* have slices cut from the breast lengthwise. In carving either of these kinds of poultry, the chief art consists in cutting as many slices as possible, no attempt being usually made at table to separate the joints of these large birds. By beginning to cut the slices at the wing, and proceeding upward towards the ridge of the breast bone, many more slices may be obtained than by the more usual plan of cutting them from the breast bone down to the wing. No parts of the turkey are considered as prime except the slices from the breast. The legs are dark-coloured, and have none of the delicacy of the breast; but, when *devilled*, they are relishing and generally liked.

4766. *Of a goose* every part is juicy and good; the breast, however, is the most esteemed.

4767. *Pigeons* are cut through the neck, *fig.* 768, straight through the whole bird, dividing it into two equal parts. They may also be divided, and it is the more modern way, from *b* to *c*. The *croup*, or lower part, with the thigh, is preferred to the upper half of the pigeon.

Fig. 768.



4768. *Game.—The breast of the pheasant* is sliced like that of the turkey, and the rest of the bird is cut up like the common fowl. In taking off the wing a little difficulty sometimes occurs, and is caused by attempting to enter the knife too near the neck bone. from which the wing has to be separated: but here practice only can enable the carver to find out readily the precise point which his knife is to attack. *Breast, wings*, and *merrythought* are the prime parts; the brains are also prized by the true lovers of game.

4769. *The partridge* is cut up like a fowl, with the exception of the breast, from which the merrythought is not separated unless the bird is larger than common. The wing is the prime part, the tip of which is considered as particularly delicate. Of almost all birds the breasts and wings are the prime parts, except in the woodcock, the heathcock, and gray hen, of which the legs are esteemed the most delicate part.

4770. *Hare* may be carved in two ways: when young, the knife may be entered near the shoulder, at *a*, *fig.* 769, and cut down to *b* on each side of the back bone. This done, the hare will be in three parts. The back is to be again divided into four parts according to the dotted lines in the cut. These divisions of the back are, with the legs, the best parts, although the wings (shoulders), called the sportsman's portion, are prized by some. They are taken off easily in the direction of *c d c*. The parts, each laid neatly on a plate, are served with stuffing, gravy and currant jelly, and melted butter. In an *old hare* the division down the back cannot be attempted, as the hardness of the bone would turn the edge of the knife; instead of which fillets of meat are cut away from the sides, and distributed in moderately-sized pieces. The legs and wings are then cut off; the neck separated from the trunk, which may be divided, at different parts of the vertebræ, into three parts. From the tail end division of the back two side bones may also be separated. If the brains are asked for, the head must be cut off from the neck, and, with the fork, it must be fixed firmly to the dish. Then the point of the knife may be entered at a vulnerable part of the head, which it will readily cleave in two. In the cavity the brains will be seen and easily taken out.

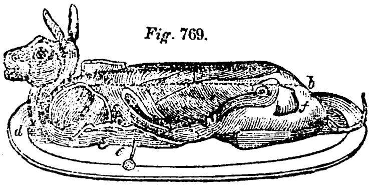


Fig. 769.

4771. *Rabbits* are carved in the same manner as hares, with the exception of the back, which is divided into two parts only, and which, with the legs, is considered as the most delicate part.

4772. *Butcher's meat*, in carving, chiefly requires a good carving-knife and a little practice. The general custom is to cut slices of beef (particularly boiled beef) and veal rather thin; mutton and pork somewhat thicker.

4773. *In a sirloin of beef* the inside meat should be cut across the joint; the outside, lengthwise with the bones. Meat from ribs of beef is cut in thin slices lengthwise with the bones, unless the meat is boned and rolled, when it is cut as a round of beef.

4774. *Of a leg of mutton* the first slice should be taken out, as at *a*, *fig.* 770, between the knuckle, *b*, and the thick end. Other slices may be cut in the same direction, till the knife is stopped by the cramp bone, *c*. The leg is then turned round, and slices are taken lengthwise from the thick end towards the knuckle. The best slices in a leg of mutton are from the upper end, although the parts about the knuckle are sometimes preferred, and which it is desirable should be eaten while hot, being hard, dry, and less agreeable when cold.

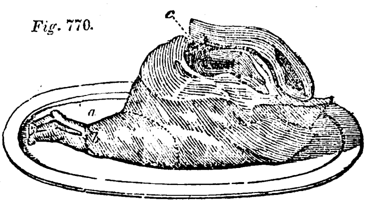

Fig. 770.

4775. *A haunch of mutton and a haunch of venison* are sent to table with the outside of the leg uppermost, and are each carved alike, being cut down to the bone in the direction of the line *a b c*, *fig.* 771, by which means the gravy escapes into the dish. The broad end is then turned towards the carver, who cuts deep in from *b* to *d*, and gives with each slice a due proportion of fat, which lies chiefly on the left side of the line *b d*. The fat of venison is esteemed as a great delicacy.

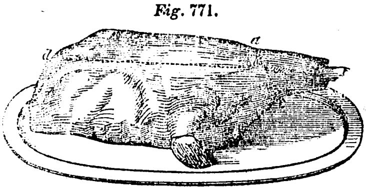

Fig. 771.

4776. *The saddle of mutton* is considered as a prime joint, but not an economical one, much of it consisting of fat and bone. It is carved in slices taken lengthwise with the bone.

4777. *In a fore quarter of lamb* the shoulder is first separated from the ribs or target, upon which a small piece of butter, some lemon juice, pepper and salt, are sometimes put, and the shoulder is then replaced for a time. The brisket is cut off from the ribs, and divided into small pieces; according to the choice of those to be served, the different parts of the quarter are distributed. The ribs under the shoulder are the choicest parts.

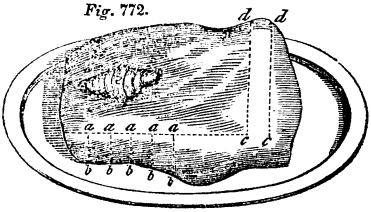

Fig. 772.

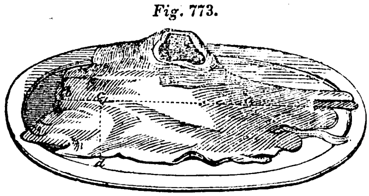
4778. *A breast of veal* (roasted) should be cut down quite through in the first line on the left of *d c*, *fig.* 772, and then in the line *a c*, thus separating the two parts of the breast, *brisket* and *ribs*. The brisket is again divided in the lines *a b*. It is preferred by some to the rib bones, which last are separated from each other in the lines *d c*. With this joint the *sweetbread* is often roasted, and is distributed in small portions with the meat.

4779. *In a boiled calf's head* there are many choice parts. The first cut, in the direction *c b*, *fig.* 773, is along the cheek bone in the fleshy part. At the end of the jaw bone lies the *throat sweetbread*, esteemed the best part of the head, and to be cut out in the direction *c d*. The *eye part*, also a delicacy, is cut out from its socket, *a*, by forcing the point of the carving knife down to the bottom on one edge of the socket, and cutting quite round, keeping the point of the knife slanting towards the middle. *The palate*, another choice part, is found on the under side of the roof of the mouth, a crinkled, white, thick skin, which is easily cut away from the bone. Some good meat and fat (of which many are fond) may be met with on the under side, covering the under jaw, and near the ear. The tongue and brains are usually served in a separate dish, but are eaten with the meat. The root end of the tongue is reckoned the best.

Fig. 773.



4780. *A ham* is generally cut in the direction *a b*, *fig.* 774, down to the bone, and through the prime part of the ham. Another mode is to cut a small hole at *c*, and to pare out of it thin circular slices. The best part of the ham is thus begun upon immediately, without the gravy escaping into the dish, the loss of which is the cause of cold ham eating dry.

Fig. 774.

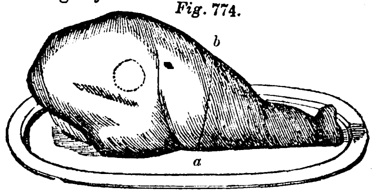


Fig. 775.

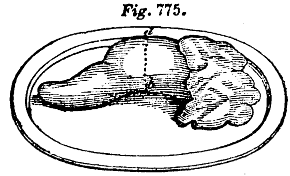
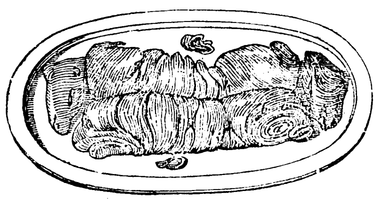


4781. *A beef tongue*, *fig.* 775, is cut across in the line *a b*, whence slices of moderate thickness are taken on each side, those midway between the root and tip being most juicy. The feet and kernels, liked by many people, are cut away from the under side.

4782. *A roasted pig* is never sent whole to table, but cut up and laid on the dish, in the manner represented in *fig.* 776, and the dish garnished with the chaps and ears. The shoulder and leg, at each end of the ribs, must be separated from them by passing the knife under each in the circular direction of the dotted lines *c d e*. The triangular piece of the neck, to be cut off in the line *f g*, is the most approved part; next to which are the ribs, divided in the lines *a b c*; and to these, some parts of the leg and shoulder.

Fig. 776.



4783. *In helping to fruit tarts*, it is usual to cut the pastry into triangular pieces; and care should be taken that, in distributing the fruit and sirup, an equal portion be given to each piece of crust.

4784. *A trifle*, composed of layers of sweetmeats and cakes, should be cut with a spoon down to the bottom of the dish, and the mass should be lifted up and laid on the plate, without disturbing it or shaking it up, as is frequently done.

SECT. III.—ARRANGEMENT OF THE TABLE AND ORDER OF THE COURSES.

4785. *In treating of the management and arrangement* of the table, it will be requisite to propose bills of fare, to determine the number and order of the courses, and the position of each dish on table, according to the prevalent style of the day.

It may be imagined that the different circumstances in which the various circles of social life are placed call for standards as to expense and style appropriate to each; but on such it would be difficult to determine. Every principal of a family must decide for himself as to the limits of his table expenses. Here the design is to describe the general style of the day, without neglecting to give such details as in practice may be adopted or rejected, limited or extended, according to the taste and judgment of the different individuals who may consult this work.

4786. *The general style of the table*, in fashionable circles, is lightness and elegance, variety in the dishes, and delicacy to the eye and the palate. The table no longer "groans under the weight of barons and sirloins of beef," nor does it present in one view the same crowded picture of substantial fare as in olden times. The variety and number of dishes of which, in the present day, a dinner is composed may not be inferior to those of former days, but they are not exhibited at once; they are presented at different intervals of the dinner in the form of courses and removes.

The style of the table, in the houses of the affluent and fashionable, is the same every day, no variations occurring but such as the seasons, or the fluctuations in the numbers of the daily party, render necessary or desirable. In such houses, cooks regularly trained to the business of the table, accustomed to draw up bills of fare for each season, as well as to prepare the principal dishes, and to superintend the whole kitchen department, are indispensable members of the household. To such the directions, observations, and receipts here given may be of less value than to cooks living in families whose table, on ordinary days, is simply and plainly served, but which is distinguished, when dinner parties are given, by more display, and by choicer cooking and arrangement.

4787. *The style of the daily table*, in families of the middle rank, is determined often by circumstances of choice, convenience, and economy, rather than by considerations of elegance and style, although, in many cases, attention to these might be given without additional expense being incurred; and, by increasing the comfort and refining the habits of a family circle, it might be one means of giving a tone to its taste and manners consistent with the cultivation of mind now generally attained. Attention to the every-day style of the table is an improvement to servants also, rendering less instruction and prompting necessary when any extra attention to propriety and nicety is called for.

Order of the Courses.

4788. *Dinners in good style* consist of either two or three courses: the first, fish and soup; the second, of meats variously prepared, and of which the side and corner dishes are called *entrées;* the third of game, when in season, with flank and corner dishes, called *entremêts* by the French, consisting of jellies, creams, pastry, and other confectionery; vegetables, dressed *à la François*, are also sometimes introduced as *entremêts.*

4789. *In a dinner of two courses*, *fish* and *soup* are often brought in with the entrées at the flanks and corners, and are removed by dishes of meat or poultry. In the most fashionable dinners there are generally two removes of the principal dishes in each course; each must consist of the same number of dishes; for instance, if in the first course there are six entrées, in the second there must be six entremêts.

4790. *In the first course the principal dishes* are usually of English cookery, *the entrées* of French. A centre dish, such as cold game pie, or other savoury pie, may, without impropriety, remain on the table till the removal of the second course; when it is to be left during the course, it is called in the bill of fare a *dormant.*

Symmetry in the order of the dishes must be preserved. Thus, puff pastry on one side should have a corresponding dish on the other of short pastry. In all cases opposite corners should have corresponding dishes.

4791. *In second courses* the flank or side dishes may have vegetables prepared in the French style, and be removed by fondus soufflé, &c.; or, in smaller dinners, when flank dishes are omitted, two of the corners may consist of vegetable entremêts, the other two of sweet dishes.

4792. *The bill of fare* of each course should be neatly drawn up on a porcelain slate, and placed at the head of the table for the convenience of the presiding lady.

4793. *The butler* should also be provided with a bill of fare, as on him devolves the charge of removing and placing properly each dish.

BILLS OF FARE.

TABLE FOR 14, 16, OR 18 COVERS.

First Course.

	Potage à la Condé. 1st remove, Turbot (lobster sauce). 2d remove, Beef à la Flamande.	
Casserole of minced fowl. Sauce au velouté.		Oyster patties.
Fillets of rabbits à l'Espagnole.		Partridges, aux choux à l'essence.
Potage à la Brunoire. 1st remove, Slices of broiled salmon. 2d remove, Fowl à la Montmorenci.	Plateau.	Purée of hare. 1st remove, Fillets of fried soles. 2d remove, Ham glazed à l'essence.
Scolloped fillets of fowl (and Truffes).		Rissole of game.
Patés en timbale.		Croustade of woodcock.
	Potage à la Reine with vermicelli. 1st remove, Slices of cod. 2d remove, Loin of veal roasted and glazed.	

Second Course.

	Roasted fowl (garnished with cresses). Remove, Fondu of cheesecake.	
Maccaroni (à l'Italienne).		Poached eggs (clarified gravy).
Spinach (à la crême).		Broccoli (au velouté).
Roasted snipes.	Plateau.	Roasted woodcocks.
Remove, Soufflé (of arrow-root and citron).		Remove, Soufflé (of rice à l'orange).
Jelly (de Noyeau rouge).		Italian cheese (à l'orange).
Charlotte of apples and apricots.		French tourte.
	Larded pheasant (roasted). Remove, Rameguires (au Parmesan).	

TABLE FOR 12 OR 14 COVERS.

First Course.

	Potage à la Condé. 1st remove, Brill (shrimp sauce). 2d remove, Turkey (boned and stuffed with a tongue).	
Cotelettes (à la soubise).		Salmi de perdrix.
Vol au vent d'escalopes de cabilleau (à la crême).	Dormant.	Casserole au ris d'un hachier de gibier (au fumez).
Escalopes de la preaux (à la Conté).		Cotelettes de fillets de poulets gras (en epigramme).
	Potage (la Brunoire). 1st remove, Slices of salmon (broiled). 2d remove, Saddle of mutton (venison sauce).	

Second Course.

	Two woodcocks (roasted).	
Truffes entieres (au vin de Champagne).		Lobster salad.
Les epinards au consommé (garni do croutons).	Dormant.	Cardons à l'Espagne à la Moelle (à l'essence).
Gateaux (à la Polonaise) garni de confitures.		Jelée d'orange.
	Two partridges.	

TABLE FOR 8 OR 10 COVERS.

First Course.

	Slices of cod (oyster sauce). Remove, Curry of veal.	
Cotelettes de poulardes.		Oyster patties.
Spinach (au consommé).	Plateau.	Beans (à la Lyonnaise).
Vol au vent (with ragout).		Rabbits sauté.
	Clear gravy soup. Remove, Haunch of Welsh Mutton.	

Second Course.

	Three quails. Remove, Soufflé (de fleur d'orange).	
French tourte d'abricot.		Madeira wine jelly.
Curdons (in essence of marrow).	Plateau.	Mushrooms croutés.
Italian jelly.		Beignets de framboises.
	Pheasant. Remove, Maccaroni.	

TABLE FOR 6 OR 8 COVERS.

First Course.

	Potage Printanniere. Remove, Calf's head (du prits certain).	
Fricassée of chicken.		Fillets of fowl (sauté au sauce suprême).
	Plateau.	
Casserole of rice, with brown ragout.		Patties or vol au vent.
	Fillets of fried soles, shrimp sauce. Remove, Saddle of small mutton.	

Second Course.

	Fowl, roasted (garnished with capers). Remove, Soufflé (with lemon peel).	
Asparagus, plain butter.	Plateau.	Cauliflower, sauce velouté.
Blancmange.		Orange jellies.
	Three quails, roasted. Remove, Rameguires.	

ANOTHER TABLE FOR 6 OR 8 COVERS.

First Course.			Second Course.		
	Vermicelli (white soup). Remove, Salmon (lobster sauce).			Fowl à la Tergue. Remove, Savoury omelettes.	
Beef palates (purée of cucumbers).	Plateau.	Sweetbreads (sauce à la financiere).	Vol au vents of sweetmeats.	Plateau.	Beignets d'Abricot.
Granadins de veau.		Cotelettes à la soubise.	Jelée de frais framboises.		Italian cheese.
	Asparagus soup. Remove, Braised leg of mutton.			Neck of venison (roasted). Remove, Soufflé de citron.	

FAMILY DINNERS FROM 8 TO 12 IN NUMBER.

First Course.			Second Course.		
	Soup (vermicelli). Remove, Boiled fowl (white sauce).			Maccaroni pudding.	
Pease.		Cauliflower.	Custard and codlings.		Stewed pears.
Ham (glazed).	Plateau.	Beef palates (and cucumbers).	Cheese cakes.	Plateau.	Puffs.
Mashed potatoes.		Young potatoes.	Jelly.		Rice, Blanc-mange.
	Roast haunch of mutton (sweet sauce).			French tourte of currants and raspberries.	

FAMILY DINNERS FROM 8 TO 12 COVERS.

First Course.			Second Course.		
	Clear gravy soup. Remove, Cod's head and shoulders (oyster sauce).			Omelette.	
Beef palates.		Rissole of game.	Jelly.		Custards.
Fowl, or rabbit curry, with rice.	Plateau.	Mutton chops (à la Maintenon).	Lobster salad.	Plateau.	Rissole of potatoes.
Sweetbreads (fricassèe sauce).		Minced veal (and mushrooms).	Apple fritters.		Cheesecakes.
	Roast beef.			Roasted pheasant.	

SECT. IV.—PREPARATION OF MEAT, ETC., FOR COOKING, AND DIRECTIONS FOR COOKING PROCESSES.

SUBSECT. 1.—*Instruction for young Cooks.*

4794. *Instruction* in the elementary details of cooking must always be essential to young cooks, who, in the outset of their life of service, require some quicker mode of obtaining the knowledge of their duties than their own experience could give them. Young servants have not, in the present day, so much practical instruction from their mistresses as was the case in former times, when all ladies, except those of the highest rank, superintended and assisted in the preparations for " well-served tables."

The chief processes in English cooking are *boiling*, *stewing*, *roasting*, *frying*, and *broiling*. Directions for each will be found in the following subsection :

SUBSECT. 2.—*Particular Directions for Cooking Processes.*

In Book XI., Chapter II., we gave the rationale of the several processes employed in cooking. We now proceed to give particular directions for the cook.

4795. *Boiling.*—Meats, whether salted or fresh, should be put, when they are to be boiled, into sauce-pans of cold water, that the meat may gradually grow warm as the water increases in heat. The quantity of water in which meat is boiled should be sufficient to cover it, but no more ; and as it wastes away in boiling, the cook should frequently renew the quantity by adding a cup of warm water to it. If she add cold water she checks the boiling of the water considerably, and the time allowed for boiling it is thus wasted. Water in which meat is boiling throws up a scum, which must be skimmed off as fast as it rises. If this be not done, the neglect will be apparent in the black streaks which will settle on the meat in serving.

As soon as the water boils, the sauce-pan or kettle containing it should be drawn off the fire, but placed near enough to it to keep it *simmering*. Meat is more thoroughly cooked by gentle than by fast boiling, which hardens it.

The allowance of time for boiling meat, and for roasting also, is, in the summer, at the rate of a quarter of an hour to one pound of meat ; in the winter, twenty minutes to the pound.

Salt and dried meats, such as briskets of beef, hams, and tongues, require very slow boiling ; and hence much more time must be allowed for them than for fresh meats. Old meats, such as beef and mutton, require a less allowance of time both for roasting and boiling than do the young meats, such as veal and lamb. The reader is referred to p. 863 for a table of time for boiling, roasting, &c.

4796. *Stewing.*—The water into which the meat has been put to stew should be allowed to boil, and should be kept boiling until the scum ceases to rise, and has been carefully removed. The sauce-pan must then be covered closely and placed near enough to the fire to keep the contents simmering, or to one regular, moderate temperature, until the meat is become as tender as the nature of the dish of which it is to be the basis requires.

4797. *Roasting.*—Slow roasting is as desirable as slow boiling; and, that the process should commence gradually, it is desirable to put the joint down to roast very soon after the fire has been supplied with the quantity of fuel which the roast in question will require to be consumed before it is sufficiently done. By putting down the meat before the whole mass of fuel is ignited, the heat, increasing by degrees, communicates itself to the meat in the same gradual manner, and in due time reaches the interior of the joint.

The fire should always be proportioned to the size of the joint to be roasted: that which is but just sufficient to roast a noble sirloin will parch up a lighter joint.

Before the meat is put down, the lower bars of the fire should be raked and cleared of every smoky coal in front.

The distance at which meat should be put from the fire is from nine to twelve or thirteen inches. At the farthest point it should be put at first, and brought closer by degrees.

The fat, as well as those parts of a joint in which there is no great thickness of meat, should be protected from the full force of the fire requisite for the other parts, by having paper skewered over them, or by covering them with a coarse paste of flour and water, fastened on with paper and string. This latter mode is very commonly employed by professed cooks, and taken off only in time to brown and froth the meat. When a paper cover is used, it should be fastened on with twine rather than skewers, which allowing it to start from the meat toward the fire, it becomes scorched, and distastes and colours the surface of the joint.

4798. *The time allowed for roasting* varies according to circumstances; *old meats*, beef and mutton, require less roasting than young.

Fat meat requires more roasting than lean. The usual allowance of time is a quarter of an hour to each pound of meat; but Dr. Kitchener recommends twenty minutes to be given, and it is desirable to add five minutes to this allowance when cold weather affects meat, or when meat is too recently killed.

4799. Other details respecting roasting must here be noticed. *Basting*, *browning*, *frothing*, and *dredging* are each of importance to the success of roasting, whether of meat, poultry, or game.

Basting is the act of moistening meat, while before an open fire, with certain ingredients which assist the roast, prevent its juices from being dried up, the meat from becoming insipid, and its surface from being scorched. Meat should be basted about every ten minutes at first, and towards the close of the roasting still more frequently. Beef and mutton, while roasting, yield generally sufficient dripping, with which they may be basted. Veal and poultry being of a dry nature, require an addition of butter, dripping, or suet, in order to have a sufficient basting for them.

To some meats flavoured bastings are used. Mutton and lamb are sometimes basted with claret and sweet herbs and butter. *A hare* is basted usually with salt and water, or with milk for the first half hour; afterward this is poured away, and butter substituted. *For basting pig*, Dr. Kitchener recommends cream and melted butter. *For veal* and other white meats, the yolks of six eggs, grated biscuits, and the juice of an orange. For all common roast, butter, clarified suet, or dripping are the most usual bastings.

4800. *Browning meat* should commence when the meat is half done by stirring the fire and making it brisker. When a good brown is not obtained, the appearance of the joint will be improved by the addition of a glaze.

4801. *Frothing* is done a few minutes only before the meat is served. As soon as the steam of the roast draws towards the fire, showing that the meat is sufficiently roasted, the cook should lightly, but uniformly, dredge with flour the whole surface of the joint, and immediately baste it with butter or dripping. The briskness of the fire should be increased by stirring, and in three minutes the meat should be taken down and served. *Poultry*, *game*, *veal*, and *lamb* should be frothed with butter; for beef or mutton, dripping answers as well. The object of *frothing* is to plump up the skin of meat or poultry, by which the appearance of the joint is much improved.

4802. *The dredgings* used in frothing are sometimes composed of other ingredients besides flour, as a means of giving some particular flavour to the meat. Of dredgings, there are, 1st, flour and grated bread; 2d, sweet herbs, dried, powdered, and mixed with flour; 3d, sugar finely powdered, and mixed with pounded cinnamon and grated bread 4th, lemon peel, dried, pounded, and mixed with flour; 5th, fennel seed, corianders, cinnamon, and sugar, finely beaten, and mixed with grated bread.

In roasting joints of which the meat is thick, it is desirable that heat should be only gradually applied. But in broiling the case is different; the quicker the process the better. Drying up the juices is to be avoided, as it hardens also the fibres of the meat; hence the degree of intensity of the fire must be attended to, and adapted to the particular kinds of meats about to be broiled. Beef and mutton, for instance, require a brisker fire than veal or pork, fish or poultry. *Uniform thickness* of the steak or chop is desirable, that the whole may be equally done. *Beef-steaks* should scarcely exceed in thickness half an inch. *Mutton* may be, without disadvantage, somewhat thicker.

Salt should not be sprinkled on chops or steaks either before or while broiling, as it draws out the gravy. Pepper may be used, if approved.

Steaks or Chops.—When steaks or chops are broiled or fried, they should be turned with steak tongs. If a fork be used, it opens courses for the juices of the meat to escape from it.

4803. *Frying*, like broiling, is a species of quick roasting done in an iron pan: in regard to the uniformity of the thickness of the steaks, and as to the degree of heat to be given to the different meats, nearly the same directions will serve as in broiling. In frying, the pan requires to be made hot by boiling in it either dripping, oil, or butter; the substance to be dressed is put into this boiling liquid, the depth of which should not be sufficient to immerse it, but only to cover completely the bottom of the pan, and to keep moist the surface of the meat. The latter should be frequently turned from one side to the other, and when nearly done, it may be more deeply browned by pressing it firmly for one or two seconds against the bottom of the pan. *Fish* is best fried in oil or lard. *Meat* is fried in beef dripping or suet.

Subsect. 3.—*Allowance of Time for Cooking Processes.*

TABLE I.

Allowance of Time for boiling Butcher's Meats, Poultry, and Dried Meats.

		Lbs.	Hours.
Beef.	The round	25	4½
	Edge bone	12	3
	Brisket	10	4 to 5
	(A hard part requiring long and slow boiling.)		
		Lbs.	Hours.
Mutton.	Leg	9	3
	Neck	6	2
Lamb.	Leg	5	2
Pork.	Leg	8	3½
	Hand	4	1½
	Pig's feet and ears		3
Poultry.	Turkey, according to size, from an hour to two hours.		
	Fowls, from half an hour to three quarters of an hour.		
	Chickens, twenty minutes.		
	The time of reckoning begins from the time the water begins to boil.		
Boiling dried Meats.		Lbs.	Hours.
	Ham	16	4
	Bacon	2	1
	Pig's face		2
	Beef tongue		2 to 4

TABLE II.

Allowance of Time for roasting Meats and Poultry.

		Lbs.	Hours.
Beef.	Sirloin	16	4
	Ribs	14	3½
Veal.	Fillet	12	3½
	Loin	10	2½
	Breast	8	2
	Neck	8	2½
	Shoulder	10	3
Mutton.	Saddle	12	3
	Leg	10	2½
	Shoulder	7	2
Lamo.	Hind quarter	10	3
	Fore quarter	9	2½
	Leg	4	1½
	Loin	3	1
Pork.	Leg	8	3
	Loin	7	2½
	Sparerib	6	2
	Little pig		1½
Poultry.	Turkey		1½ to 2
	Fowls		½
	Chickens		15 min.
	Ducks		20 min.
	Ducklings		10½ min.

Subsect. 4.—*Preparing Fish for Cooking.*

Fish, in London, is prepared for the cook by the fishmonger from whom it is purchased; but in the country, all that is necessary to be done in trimming and cleaning it devolves on the cook, or on her subordinate assistants. Fish requires to be well washed; but it should not be long soaked in water, or the flavour will be impaired.

4804. *Salmon, herrings*, and other scaled fish must be scraped carefully with a blunt knife, until every scale is loosened and can be washed away. The smooth-skinned fish must be more carefully handled. They require washing only; but whether scaly or smooth, fish is considered as disfigured if, either in cleaning or in cooking, the skin be broken. The inside of fish requires to be well cleansed, to effect which a small slit must be made with a knife on the under side, through which the entrails may be drawn. Within these, in cod and salmon, will be found the roe and liver, which must be separated from them, washed and laid on a clean dish ready to be cooked with the fish. The roe of all fish is considered as a delicacy, and as a proof of the fish being in season; it is therefore always dressed with the fish.

4805. *Eels*, and other fresh-water fish, *pike, carp*, and *tench*, are slimy when first caught, and require the utmost care to cleanse them well, or there will be in them a muddy taste and smell, which is strong enough even to overpower the flavour of the ingredients with which some of these fish are usually cooked. Washing them, or, perhaps, scalding them in salt and water, is better still for removing the slime adhering to them, but if scalded, the fish must be perfectly dried again before it is cooked.

Subsect. 5.—*Preparing Poultry, Game, and Wild Fowl for Cooking.*

4806. *The feathers of poultry* should be plucked as soon as possible after it is killed. When it becomes cold a stiffness takes place, which renders it difficult to draw out the quills without tearing the skin, which, after cooking, is considered as a disfigurement. *The down* which remains after the feathers are removed is afterward singed off with lighted paper. From some birds it is requisite to draw out the sinews of the leg, which is effected by binding the joint close to the claw, and fastening the claw in a vice. The bird is then pulled strongly until the sinews give way.

The crop is next to be emptied; a slit cut in the back of the neck opens into the crop, and allows the contents to pass through it.

The vent is then opened that the entrails may be cleaned out; in doing this, the gall-bag must be carefully removed; if broken, its contents will impart a bitterness to the flavour of the liver which washing will scarcely remove. When the bird is drawn, the liver and gizzard are separated from the rest of the entrails, and put into cold water to be cleansed.

The necks of fowls, geese, and ducks are always cut off close to the body. Before this is done, the skin which hangs loosely upon the neck is pushed up above the part at which it is to be cut off, that it may be afterward drawn down and wrapped over the end of the neck to hide it from view. Before it is fastened down, cold water should be poured through the body of the fowl, a practice not observed by the poulterers when they truss fowls, but to which it is very proper to attend. The backbone and the two bones which lead to the pinions are afterward broken. All this done, the bird is then to be *trussed*.

4807. *Trussing for roasting fowls* is done by cutting off the first joint only of the legs, and by turning them down close to the sides towards the vent, and fastening them by a game skewer passed from one to the other. Another slight skewer is passed through the joint of one wing into the body, and through to the opposite wing. The liver and gizzard are placed one under each wing.

In trussing fowls for boiling, the whole of the leg, except the thigh, is cut off, the end bones of which are tucked into the apron. The breast is set up to look plump; the wings, with the liver and gizzard, are placed the same as for roasting. The whole is tied in proper form with a slight string, which, upon serving, is cut and removed.

In trussing a goose, the legs, feet, and pinions are cut off; and these, with the neck, head, liver, and gizzard, form what are termed *giblets*. *Of a turkey, pheasant, partridge*, and *moor fowl*, the heads, in trussing, are not cut off, but are twisted round one of the wings, generally that under which the liver is put.

4808. *Boning poultry* is become fashionable, and, indeed, it is requisite when French dishes are to be formed out of it. It is an art that professed cooks practise; but in London it is generally done by poulterers, who have the proper instruments for performing it cleverly.

4809. *To truss fowls, en poule*, as described for French dishes, a hole must be made above the joint of the leg, and the claws skewered into the body. A string is passed from the head to the skewers, which preserves the form of the chicken while it is cooking; but it is to be removed on serving.

4810. *Woodcocks, snipes, and other birds living by suction*, are never drawn. The trail, as the inside is termed, is considered as the most delicate part of these birds. *Woodcocks*, in being plucked, must have the feathers most carefully drawn, as the skin is peculiarly tender, and if torn, these birds, when cooked, are much disfigured.

Moor fowl are trussed like the domestic fowl, except that it has, as well as the pheasant and partridge, the legs twisted together at the tail end, and the head twisted under the wing.

4811. *A hare* is prepared for cooking in the following mode: It is first to be *paunched*, by which is meant, as is well known, the removal of the entrails. This is sometimes done by the sportsman in the field as soon as the animal is killed; but if not, the cook should do it when it is brought into the house. If left in, it soon begins to spoil, which becomes apparent by the swelling of the body. When paunched, the inside should be kept dry; and it may also be proper to pepper it, if the hare is to be kept more than four or five days. As soon as the flesh becomes dark in colour and soft to the touch, it is time for the hare to be dressed.

To skin a Hare.—The legs must be cut off at the first joint; the skin on the back is then raised and drawn over the hind legs, and stripped away from the tail. It is afterward slipped over the fore legs, and cut away from the neck and head. The ears are carefully extricated from the skin, and left on the head. When the hare has been well soaked and washed after skinning, it is ready to be trussed. The sinews of the hind legs it will be requisite to cut, in order to turn them towards the head, and to fasten them to the sides of the hare. The fore legs are also turned to meet the hind legs, and are fastened with slight skewers to the body. The head is thrown rather back, and a skewer, if passed through it towards the tail, keeps it in place while it is cooking. A stuffing is put into the hare, to keep which within the skin is sewed up. A string ties the whole compactly together, keeping the legs in place.

4812. *Rabbits* are skinned, drawn, and trussed in the same way as hares. The ears of the rabbit are, however, cut off, whether they are to be roasted or boiled. If two rabbits are roasted together, their heads are skewered outward towards the shoulder.

SUBSECT. 6.—*Scalding and Singeing Pigs.*

4813. This is a business belonging chiefly to domestic life in the country. It is there usually performed by butchers, or by men employed in the out-door work of country families. In towns, it is always done by the butchers. It will therefore not be necessary to describe the mode in this place.

SUBSECT. 7.—*Preparing Vegetables for Cooking.*

For the general principles of treating vegetables when kept a short time previously to being cooked, we refer the reader to Book X., Chap. IV.

4814. *Plants of the cabbage tribe* must be immersed in water for more than one quarter of an hour previous to their being dressed. Long immersion renders them flavourless, although it may tend to renew the crispness they have lost since they were cut, and the toughness when eaten.

4815. *Leguminous plants*, as the pease, beans, and scarlet-runners, require less to be done than any other plants to preserve them moist. The pods for a considerable time keep the seeds from becoming dry. When pease and Windsor beans are shelled, the cook has only to put them into a colander, and to pour over them plenty of cold water. French beans and scarlet runners are cut into short, thin shreads, and then immersed for half an hour or less in cold water.

4816. *Of the esculent plants* the potato is the most important. When they are taken from the winter store, they should be put into cold water for ten or twelve hours. This immersion prepares them by a gradual transition from a low temperature to that of boiling water. For turnips and parsnips, the same practice of soaking hem in cold water should be resorted to, turnips being previously peeled; carrots and parsnips are generally scraped.

Spinach leaves must be washed in cold water, frequently changed, to remove all sand and dust from their surface. Spinach in boiling requires no more water than that which adheres to its leaves after it has been thus washed.

Asparagus, after the scaly covering on the heads have been scraped off with a blunt knife, and the stalks have been cut of a convenient length, must be put into cold water before it is tied up for boiling.

The artichoke is rather improved by being cut a few days before it is cooked; before they are cooked they should be well washed; they require long boiling, and a change of water in boiling.

Salad plants must not be kept long, nor will any continued immersion in water do them any good when they have been so long cut as to be flaccid.

SUBSECT. 8.—*Management of the Contents of the Larder.*

4817. For the construction of the larder, and the general principles for the management of the meat in it, see Book X., Chap. II. We add a few directions for the cook.

4818. *Butcher's meat*, when brought in from market, should be examined and trimmed before it is hung up. All moisture should be wiped off from its surface; all bloody veins should be cut out, at least at the surface of the meat; kernels from the fat and pith from the bones should also be removed. Uncooked butcher's meat should also be examined daily, that no "fly-blow" remain long enough undisturbed to injure it. The cook will generally find fly-blows, if there be any, between the folds of the skin and fat, or in other somewhat concealed parts. If possible, the part attacked should be cut away, but if not, it must be carefully washed off, and the part well dried. *Roasting beef* should, in the summer, have a little salt sprinkled over its surface, and if a dusting of black pepper be added, the surface will be rendered too pungent to allow the meat fly to settle upon it. *Mutton* and *veal* should be taken down and wiped each day with a clean, dry kitchen cloth. *Venison* is always hung a length of time before it is cooked. It should be frequently wiped with a dry cloth, or first washed with cold milk and water, wiped perfectly dry, and dredged with powdered ginger or pepper, to prevent the fly from settling on it; but these must be wiped off before the venison is cooked. To ascertain when it is in a condition fit to be cooked, plunge a clean knife into the fleshy part, and the smell will show the condition of the joint.

4819. *Fish*, when to be kept uncooked for a day or two, should be placed on the coolest spot which can be found in a cellar, or stone floored larder, or on a heap of moist sand, and turned twice a day. *Ice*, when it can be obtained, is, perhaps, the best preservative of the freshness of fish; but on removing it, the fish must be cooked immediately, or it will be spoiled.

For other particulars respecting the keeping of meat, the reader is referred to "Preservation of Food," Book X.

SUBSECT. 9.—*Hints respecting Dripping, Suet, &c.*

4820. *Soups, sauces, gravies, and made dishes* brought from table, and to be reserved for future dinners, ought to be poured out of the tureens and dishes in which they have been served into clean vessels, and immediately removed into the cool larder.

Soups, broths, &c., should have all vegetables in them strained off before they are set apart in the larder; for vegetables after they are cooked soon become acid, and then they injure the taste and quality of the soup or other dish of which they form a part.

Neither soup nor anything which is to be eaten should be suffered to remain till cold in copper utensils, the danger of which has already been pointed out.

4821. *Dripping* is the fat which drops from meat while roasting. If properly managed, it may be employed in frying, in basting, or in making common pastry. In cooking poultry, game, and fish, other ingredients are usually preferred to dripping, such as butter, lard, or Florence oil; but in many instances, especially in preparing plain family and economical dishes, beef-dripping would answer the same purpose, if cooks would only prepare it properly.

As dripping is too often a cook's perquisite, her interest in this matter is opposed to that of her employers, and she is seldom disinterested enough to make the best use of it, when she is not herself to benefit by it. When, however, she is so disposed, she should, when a joint of roasting beef is done, pour the melted fat in her dripping-pan into a basin of clean cold water; any heavy particles in the dripping will sink to the bottom of the basin, the melted fat will float on the surface, and when cold will form a clear cake of fat, free from taste, and fitted for any purpose of cooking in which such a kind of ingredient is requisite. In a cool larder dripping so clarified will remain fit for use for nearly a fortnight. Also, a little dripping may be made to go in use a good way, for after it has had anything fried in it, except fish and pork, or after it has basted veal or poultry, and has not been burned, it may be again poured in its melted state into cold water, and be used a second time.

4822. *Beef suet* cut into shreds, and melted in a slow oven, or in a tinned sauce-pan over a moderate fire, may be employed in frying when dripping is not to be had, and will save the more expensive articles of butter, lard, or oil. It must be slowly rendered, or it may acquire a burned taste; and when melted, it must be passed through a sieve into cold water: when it is caked it must be put into a jar, covered slightly, and placed in a cool spot.

4823. *Top pot* is the skimmings of soups and gravies, and it is spoken of by French cooks as preferable to dripping or suet for incorporating with flour in thickenings, soups, and gravies, and some even recommend its use in frying. In using everything up, the French cooks are more economical than the English cooks.

BOOK XIII.

RECEIPTS FOR ENGLISH COOKERY.

It is necessary to advertise the reader that in Book VII., Chaps. I., II., and VII., the general nature of food and principles of nutrition have been treated of; in Chaps. III., IV., V., VI., VIII., IX., and X , the various substances, both animal and vegetable, used as food have been described, and in Book X. the various methods of preserving food by salting, smoking, &c., are considered In the following receipts for actual cookery, occasional directions for salting particular parts will be added, as well as other processes intimately connected with the methods of dressing them. In Book XI., the rationale of the several processes in cookery has been explained, and a description given of the various apparatus employed.

Sect. I.—butcher's meat.

Subsect. I.—*Beef.*

In England, beef is almost always salted a little before it is boiled, and is then usually termed *corned* beef. The general principles for salting meat have been described in Book X., Chap. III., to which we refer the reader; but we here add the usual modes of salting it in this manner for a family.

For a round of beef, a pound and a half of salt, dried before a fire, must be rubbed into the meat; it is then put into a salting pan in a cool place, and the brine that melts should be returned upon the meat every day. The length of time it is to remain in salt will depend upon the degree of saltness desired, usually from three to ten days.

If the beef is required to be red, saltpetre is used. A pickle is made for twenty pounds of beef, of three pounds of common salt and one ounce of saltpetre, with two large table-spoonfuls of brown sugar. After having been well rubbed with salt, the beef is kept in this pickle for ten days or a fortnight.

Beef, to be boiled, should be put into lukewarm water, if the salting is just sufficient, but if it is thought to be too salt, then it should be put into cold water. The time of boiling allowed is a quarter of an hour for every pound of meat. The boiling should be steady, and the skimming carefully performed. The brisket requires somewhat more time than the round.

Boiled beef is served up with greens, carrots, or turnips.

4824. *Beef bouilli* is sometimes made of the rump, but it is equally good, and less expensive, if made of brisket. Put nine or ten pounds of it into a kettle with three carrots, one turnip, an onion, and some celery, all cut small; cover with cold water and set it on to boil; as the scum rises remove it carefully. Keep it gently simmering, take off the lid partially, and, as the water boils away, add as much hot water as will keep the meat covered. After thus simmering for four or five hours, draw off most of the soup and place it to cool, that the fat may be more easily removed. To the soup more vegetables, previously cut small and boiled by themselves, may be added, or it may be served in a tureen with vermicelli. The beef, from which the bones should be removed, may then be served and garnished with the vegetables boiled with it.

A sauce is sometimes served with it made of some of the soup, thickened with flour and butter, and flavoured with a thick-made mustard and the vinegar of pickled walnuts.

4825. *Rump of Beef stewed in its own Gravy.*—Boil a boned rump about eight or nine hours over a very slow fire, the pan being just covered with water. Put in a little parsley, a laurel leaf, a clove of garlic, two eschalots, a small bunch of thyme, four cloves, half a nutmeg, pepper, and salt. When done, withdraw the gravy, and cool it till the fat can be cleared away. Boil it up again, and pour over the beef when served.

4826. *Stewed Rump Steaks.*—Four pounds of rump, or, if tender, of common beef-steaks, cut very thick, must be peppered and fried brown in their own fat. Fry, also, in two ounces of butter, some carrots, cut into dice or shapes, a large bunch of parsley, and some eschalots coarsely chopped; add to these three large onions shredded, a handful of small mushrooms, and some celery cut small. Dredge the vegetables with flour, and when they begin to be tender, moisten them with a wine-glass of port wine, a pint of beef gravy, and two table-spoonfuls of strong vinegar; season these with pepper and salt, and put the steaks in them, after which the whole must simmer, but never boil, for three hours. The gravy must first be poured away from the meat and vegetables into a deep dish, and the fat must be removed from its surface; the meat and vegetables must then be added to it, and it is ready for table.

Ox Cheek Stewed.—Blanch (see terms explained) a cheek to cleanse it thoroughly; braise the cheek with thin slices of bacon, and flavour the gravy by putting in one onion, twenty peppercorns, some allspice, three slices of lemon (not peeled), and as much gravy or broth as will keep it stewing without covering it, and as this boils away more must be added. Five hours must be allowed for stewing it; and when done, the bones may be easily removed; the head being neatly trimmed and glazed, must be served with a sharp sauce, or sauce of roots.

4827. *Sirloin of Beef, roasted.*—Fifteen or twenty pounds in weight will require from three and a half to four hours' roasting. As the upper, or *outside*, as it is called, has seldom the same depth of meat as the under, or inside, it should be papered over for a couple of hours, and the fat also on the inside. Garnish it with hillocks of horseradish.

The rump of beef is sometimes roasted, and is excellent.

4828. *Ribs of beef, roasted*, should have the long thin parts papered, or the beef will be unequally roasted. A quarter of an hour to a pound of meat will allow sufficient time for roasting it, unless the weather be frosty, when an additional twenty minutes should be given to it. In hot weather, or when the meat is ripe, so much time need not be allowed. *Sauce*—horseradish, and vinegar, and water, served in a tureen.

4829. *Ribs of Beef boned and rolled like a Fillet of Veal, roasted.*—A stuffing of bread, egg, and sweet herbs is sometimes rolled up with the meat; but more frequently it is dressed simply as roasted before a brisk fire, and having an allowance of time longer than that given to the sirloin of equal weight, in consideration of the solid mass into which the beef thus prepared is formed.

4830. *Broiled Rump Steaks.*—Rump steaks should always be chosen from the best part of the rump, after it has hung a length of time sufficient to render it tender. If the weather is unfavourable for hanging meat, it is customary, after cutting off the steaks of the thickness of half an inch, to beat them with a rolling-pin. Lay the fat part of the steak towards the handle of the gridiron, and turn it with a pair of steak-tongs.

If more gravy be desired than that which the meat yields of itself, it may be procured by broiling a thick piece of gravy meat (such as part of the chuck), and when three parts done, by putting it on a dish, scoring it with a knife, and sprinkling salt upon it; this draws out a quantity of pure gravy, which being collected and kept hot, may be divided between each dish of steaks successively sent to table.

Among the condiments usually served with broiled beef-steaks are minced eschalots, scraped horseradish, walnut-pickle, or hot pot, and oyster sauce, served hot in a tureen.

4831. *Beefsteaks Fried.*—The *fat* and *lean* should be done separately. A hot dish should be in readiness to receive the lean while the fat is frying. Both being done, the butter or fat in the pan must be poured away, and some beef gravy, an anchovy, a small onion, some pepper, and salt must be put into the pan, boiled up in it, and while hot poured into the dish.

4832. *Cold roasted Beef dressed like Beefsteaks.*—Cut off the outside of the meat, and divide it into slices about half an inch in thickness. Slice two or three onions, and fry them in some butter till they are of a light brown; be careful not to burn them, or the gravy will be spoiled. Take them out of the pan, and then fry the beef of a light brown also. If too much fried, it will be hard and dried; but when sufficiently done, remove it from the pan to the dish on which it is to be sent to table; pour away the fat from the frying-pan, and put into it a small lump of butter into which some flour has been worked, some water or gravy, two tea-spoonfuls of mushroom and two of walnut ketchup, one of anchovy essence; to this a table-spoonful of red wine may be added or not, according to taste. The fried onions must be boiled up in this gravy, and the whole poured over the beef.

4833. *Beef Tongues.*—A salted tongue, if dried, must be soaked for some hours previous to being dressed. It must then be put into *cold* water, and gently brought to boiling; when, after the surface of the water is cleared from the scum, the sauce-pan must be removed from the fire only so far as to reduce the boiling to a gentle simmering. If dried, a tongue will require four hours', if simply salted, only three hours' boiling. While hot, the outer skin of the tongue must be peeled off, and it may be sent to table either glazed or plain. Boiled turnips are a usual accompaniment of boiled tongue.

4834. *Boiled tongue*, if to be eaten cold, may be rolled, bound by a tin band, and pressed down into a solid mass. When boiled and skinned, the small gristly bones near the throat must be removed, the root end must form the centre, and the tip, being brought to the outside, is kept in place by the tin bandage; weights are then placed upon it, and it is suffered to remain thus for ten or twelve hours; and on removing the bandage the whole will form a compact fillet, whence slices of fat and lean together may be conveniently cut.

4835. *Roasted Tongue.*—Parboil a tongue that has only been salted about ten days; roast, baste it with red wine, and frost it at last with butter. Serve it with a rich gravy and sweet sauce.

4836. *Stewed Tongue.*—Simmer it for two hours in water only sufficient to cover it; then peel it and put it back into the water, adding to it, tied up in a piece of muslin, some pepper, mace, and cloves. Cut some turnips and capers very small, slice some carrots, and add these also to the liquor, with half a pint of beef gravy, a wine-glass of white wine, and a bunch of sweet herbs. Stew all together very gently for an hour and a half longer, then take out the spice and sweet herbs, and thicken the gravy with flour worked into a small piece of butter.

4837. *Beef Tongue may be dressed in various Ways.*—Slices of hot tongue may be pared, glazed, and neatly arranged round a dish, the centre of which may be filled with any vegetable pulp or mash, as turnip, spinach, green pease, sorrel, &c. Slices of tongue pared and highly seasoned may be dipped in egg and bread crumbs, fried, and served up with any of these pulps, or eaten with bechamelle sauce. A layer of the white meat of cold roasted fowl may be included between two thin slices of tongue fried in the same manner, and sent up with the same sauce, or placed on an artichoke bottom dressed with melted butter, consommé, and pepper.

4838. *Beef Palates.*—Take half a dozen beef palates, rub them with salt, and let them simmer a few minutes in any broth, that the external skin may be removed; then divide them into convenient portions. Melt in a stew-pan some butter and flour, and moisten with beef gravy; when of a proper consistence, put in the palates, and let them stew till sufficiently tender. Season according to your taste.

There are many ways of dressing palates; they may be served up with bechamelle sauce and pickled mushrooms; or they may be rolled up and contain forced meat, brushed over with egg, dipped in bread crumbs, fried and served in any rich sauce. In the same manner, they may be rolled up and include thin slices of ham and truffles, and sent to table with cucumber, tomato, or celery sauce under them.

4839. *Cow's udder* is usually roasted with a tongue that has been in pickle not more than three days. They are both parboiled, and then tied together and roasted. They are served with good gravy and currant-jelly sauce.

4840. *Cow's Heel.*—Get one that has only been scalded, not boiled till the jelly has been extracted. Boil it for seven or eight hours in a quart of water, which, if required, may be afterward made into jelly or soup. The heel, cut into handsome slices, and covered with egg and bread crumbs, must be fried of a light brown, and laid round a dish, in the centre of which some onions sliced and fried also must be put.

SUBSECT. 2.—*Veal.*

4841. *Fillet of Veal, boiled.*—Fill the centre, the bone being removed, with stuffing similar to that used for boiled turkey. Allow one quarter of an hour to a pound, and twenty minutes over, for the boiling of this joint. After the water boils, scum carefully, and let it only simmer, keeping the meat covered by adding hot water, or it will become brown. The beauty of this dish depends on delicacy in the colour of the meat. A sauce must be formed by taking out a pint of the broth which has been made in boiling; this must be thickened with good cream, butter, and flour, and flavoured with mushroom catsup and mushroom powder, or mushroom buttons. If cream be not at hand for thickening the broth, a sauce may be made by mingling the yolks of two eggs with flour, butter, and broth.

4842. *Boiled Knuckle of Veal.*—As veal is insipid, it is a meat seldom boiled. The knuckle, however, being chiefly composed of cartilage, is occasionally boiled, and requires stewing to render it fit for eating. It is sometimes boiled with rice, and the gravy drawn from it is flavoured with onions, a little mace, and a few peppercorns. With the broth half a pint of cream or milk may be mixed, and the whole, meat, rice, and broth, served together in a tureen. If sent up separately, the veal will require a sauce of parsley and butter, as well as the accompaniment of boiled bacon, on a separate dish.

4843. *Veal Stewed.*—Divide part of a breast of veal into portions, and fry it of a nice brown in clarified butter. Put a quart of green pease into a stew-pan, pour on them some melted butter, and let them gently stew with some green onions, parsley, and cabbage lettuce; when sufficiently tender, add some veal gravy, put in the pieces of veal, and stew them gently. Season with salt, pepper, or cayenne, and add a tea-spoonful of powdered sugar. If you prefer it, you may pass the vegetables through a tamis, reduce the pulp, add the yolk of an egg and a spoonful of cream; in this case the pieces of veal may be glazed, and fried bread served round the dish.

4844. *Stewed Veal Cutlets.*—Cut a piece of the fillet into three parts, and trim from them all the skin. Stew all the trimmings with carrots and onions, to make a light gravy, then add a little broth or warm water; add spice, if approved, put in the pieces of veal, and stew them for two hours. Thicken the gravy, and pour over them.

4845. *The fillet of veal* is most commonly roasted, being previously stuffed either in the flap or in the space in the centre from which the bone has been taken. Veal, being a dry meat, requires constant basting, either with butter, beef dripping, or suet. It must be roasted *thoroughly* (under-done veal being neither wholesome nor agreeable) and of a nice brown. When dished, half a pint of melted butter, sometimes mixed with a brown gravy, is poured over it. Curry sauce in a tureen may also be served with it. Bacon, or fried pork sausage balls, with greens, are among the accompaniments of roasted veal.

4846. *Loin of Veal, roasted.*—The loin is never stuffed, but simply roasted and served with melted butter poured over it, with bacon and greens as separate dishes. The fat at one end and the chump at the other should both be protected for an hour from the full heat of the fire by being covered with paper.

4847. *Shoulder of Veal, roasted.*—The knuckle is taken off just above the joint, and on the upper side a stuffing, such as with the fillet, is laid under the loose skin, and skewered down. The joint is then roasted, and served with gravy or melted butter.

4848. *Breast of Veal, roasted.*—Cut off the thin end, and roast scarcely more than according to the common allowance of time. Baste constantly, or the skin becomes dry and hard. When served, pour melted butter or gravy over it, and put toasted bread under the kidneys. Accompaniments—bacon, greens, French beans, &c.

4849. *Breast of Veal, roasted, with Oyster Sauce.*—Roast a breast of veal in a caul; when nearly done, remove the caul that it may become lightly brown, glaze it, and serve it up with oyster sauce seasoned with cayenne pepper and lemon juice.

4850. *Broiled Veal Cutlets.*—Let the veal be cut of an equal thickness, and divide it into portions convenient to help at table. Dip the pieces into beaten egg, and cover them, but not too thickly, with chopped herbs, as parsley, mushrooms, and a little grated lemon peel; strew over them crumbs of bread, and broil them of a fine brown. Broil some thin slices of bacon. Make ready a sauce with butter and flour melted brown, moisten it with veal gravy and a little cavice; when it is intimately mixed, throw in some pickled button mushrooms, and pour the sauce quite hot over the cutlets; let the slices of bacon be placed round the dish. If lemon juice be required, it may be added at table.

4851. *Veal Chops.*—Cut the chops from the loin with a slice of the kidney and a portion of the fat. Broil of a light brown, and send it up very hot, but not burned. By many, veal alone is considered insipid, and this dish is considerably improved by the following method: Beat some lean of dressed ham in a mortar, with a little of the kidney fat; add chopped parsley, some parings of mushrooms, and an eschalot, with pepper and salt; when intimately beaten, bind it together with the yolk of an egg. Secure this forced meat, and broil it with the chop in buttered paper. For sauce, melted butter, button mushrooms pickled, and a tea-spoonful of lemon juice.

4852. *Veal Olives.*—Cut some thin slices of bacon or ham, and lay on them slices of veal of the same size and thickness; rub the veal over with yolk of egg, and pepper it; prepare some forced meat of a thinner consistence than usual, that it may be spread over the veal. Roll them up, and secure them in that position with some thread; run a lark spit through them, and roast them. Prepare a sauce of veal gravy, a spoonful or two of cream, and a little cavice.

4853. *Italian Collops.*—Mince a quantity of lean, undressed veal; add a little flour to prevent the divided pieces from sticking together, with half the quantity of young, green onions, a little parsley, button mushrooms, all chopped together, with a very little grated lemon peel. Put the chopped veal and herbs into the pan with a piece of butter, frequently stirring, that the whole may be equally done. Moisten to a proper consistence with veal gravy, and a spoonful of cream. Add sufficient salt and pepper; lemon juice, if required, may be used at table.

4854. *Fricandeau of veal* is cut from the fat side of the leg, about nine inches long, and half as thick and broad. Beat it with the rolling-pin, take off the skin, and trim it with the rough edges. Lard the top and sides, cover it with fat bacon, and then with white paper. Lay it in the stew-pan with pieces of undressed veal or mutton, four onions, a carrot sliced, some sweet herbs, four blades of mace, four bay leaves, a pint of good veal or mutton broth, and four or five ounces of lean ham. Cover the pan close, and let it stew gently for three hours. Take up the meat, remove all the fat from the gravy, and boil it quick to a glaze; then glaze it. Serve with sorrel sauce.

4855. *Veal Cutlets* (fried).—*Cutlets* are generally cut from the fillet, in neat, small pieces, about half an inch in thickness. They are sprinkled over with bread crumbs, yolk of egg, sweet herbs finely broken, lemon peel grated. The cutlets must be fried in butter of a light brown. When done, the butter must be poured away, and a little gravy made in the pan with warm water or broth; some lemon juice and peel, and some mushroom catsup, thickened with flour and butter.

4856. *Calves' Brains in various Ways.*—Let the brains first steep in cold water, to extract the blood, and separate all the filaments and membranes; then pour on them boiling water, in which they are to remain a quarter of an hour. Afterward drain them, and fry them in clarified butter, and let them be served with cream and bechamelle sauce. Another way of dressing them is by beating the brains, when parboiled, to a paste in the mortar, with some chopped parsley, green onions, and chopped mushrooms; work this together with some cream and veal gravy; when properly seasoned, it may be served up with slices of tongue glazed, and neatly arranged round the dish; the French term it *en miroton;* or it may be spread on a toast, and divided into convenient pieces.

4857. *Sweetbreads done in various Ways.*—Trim them properly, and let them soak in cold water to extract the blood; afterward pour on them boiling water to blanch. Lard them, and roast them till thoroughly done. Serve them up on a square piece of toasted or fried bread, with clarified veal gravy in the dish properly seasoned. Sweetbreads may also be simply boiled, and served up with butter and flour, brought to the proper consistence by the addition of cream and a few pickled mushrooms, with seasoning. Another method is by cutting them into slices, covering with beaten egg and bread crumbs, and frying of a nice brown. These slices may be served with a sauce composed of cream, veal consommé, lemon juice, and cayenne pepper, with sufficient salt.

4858. *Boiled Calf's Head.*—Cut it in two, and take out the brains; wash the head in several waters, and soak it in warm water for a quarter of an hour. Put it into a sauce-pan of cold water, and when it comes to a boil, scum it carefully. Half a head, without the skin, will require boiling from an hour and a half to two hours and a quarter, according to its size; with the skin, an hour longer. It must be stewed very gently till tender. Boil tender eight or ten sage leaves, or parsley, or both; chop them fine, and set them ready on a plate. Wash the brains well in two waters; put them into a basin of cold water, with a little salt in it, and let them soak for an hour; then pour away the cold, and cover them with hot water; then put them into a stew-pan with plenty of cold water, and boil very gently for ten or fifteen minutes. Now chop them (*not* very fine), put them into a sauce-pan with the sage leaves, and a couple of table-spoonfuls of thin, melted butter, and a little salt (some add a little lemon juice), and stir them well together. As soon as they are well warmed, skin the tongue, trim off the roots, and put it into the middle of the dish, the brains round it; or chop the brains with an eschalot, a little parsley, and four hard-boiled eggs, and put them into a quarter of a pint of bechamelle, or white sauce. A calf's head is usually attended by a pig's cheek, a knuckle of ham or bacon, or pickled pork; greens, cauliflowers, broccoli, or pease, and always by parsley and butter. If you like it FULL-DRESSED, score it superficially, beat up the yolk of an egg, and rub it over the head with a feather; powder it with a seasoning of finely-minced, or dried and powdered winter savory, or lemon thyme, or sage, parsley, pepper, salt, and bread crumbs, and give it a brown with a salamander, or in a tin Dutch oven: when it begins to dry, sprinkle a little melted butter over it with a paste-brush. You may garnish the dish with broiled rashers of bacon.

4859. *Calf's Head, hashed.*—Soak the head in water, boil it, not thoroughly, but until the meat may be cut clean from the bone. Take the meat off the bone on the best side; lay it in a dish, and cover it with crumbs of bread, among which are a few herbs cut very small, with some pepper, salt, and nutmeg, and the yolk of two eggs. Set the dish before the fire, and keep turning it occasionally, that all parts of the meat may become brown. Slice the remainder of the head, peel and slice also the tongue. Put a pint of good gravy, or of the liquor in which the head was boiled, into a pan with an onion, a small bunch of sweet herbs, some salt, Cayenne, eschalot, a glass of sherry, and a little oyster liquor. Boil these together for a few minutes; then strain it on the meat, which should have been previously dredged with flour. Fresh, or pickled mushrooms, truffles, morels, and two spoonfuls of catsup should be added. Half the brains, beaten up with flour and butter, should be added, and the whole simmered together. The other half of the brains are to be beaten up with lemon peel and parsley finely chopped, some nutmeg, mace, and an egg. These are to be fried in small cakes; also some oysters dipped in yolk of egg; with these, and some good forced meat balls, the dish must be garnished.

SUBSECT. 3.—*Mutton.*

4860. *Leg of Mutton, boiled.*—Cut off the shank bone and trim the knuckle. Put the leg into milk-warm water for ten minutes and wash it clean; cover it with cold water in a sauce-pan, and boil, scum, and simmer gently for two hours and a half or three hours, according to its weight and to the time of the year. Serve with boiled turnips and caper sauce.

4861. *The neck of mutton* is also boiled, and served with mashed turnips and caper sauce. It should be boiled in the skin; but this should be stripped off before it is served.

4862. *Stewed Leg of Mutton.*—This is larded with bacon on the upper side, and put into a stew-pot with either water or broth, two or three carrots, one turnip, an onion, and a few black peppercorns. After the water boils it must be allowed to simmer for two hours and a half; the broth and vegetables are then taken out, the meat dredged with flour, and put again on the fire to brown, with the cover left off. The vegetables are pulped through a sieve, and boiled up with the gravy, to which a table-spoonful of vinegar has been added. Part of the sauce is poured over the meat, and the remainder sent up in a tureen.

4863. *Hotch Potch.*—Stew together, in a small quantity of water, some pease, lettuces, and onions, with a ham or beef bone. Season with pepper and salt, and fry of a good brown some mutton chops; lay them in a stew-pan and cover them with the vegetables, and stew them all together for three quarters of an hour. Serve them in a tureen.

4864. *Stewed Loin of Mutton to eat like Venison.*—The bones are taken out and boiled for gravy, which is put into the stew-pan with the mutton rolled up and tied, and half a pint of red wine, an onion, and some dried mushrooms. A seasoning of pepper and salt having been strewed on the inside of the mutton before it was rolled, the mutton must be stewed for two hours, and when taken out, a little mushroom catsup must be added to the gravy, and a thickening of butter and flour.

4865. *Shoulder of Mutton stewed with Onion Sauce.*—Hang it up for three or four days; salt it for two days. Bone it, sprinkle it with pepper and pounded mace, lay some oysters on it, roll it up and tie it. Stew it gently for two hours, closely covered, and in a very little water, and a few peppercorns. Prepare some good gravy with oysters stewed in it, and which must be thickened with flour and butter, and when the tape is removed from it, pour the sauce over it.

4866. *Haunch of Mutton, roasted.*—To roast a haunch of mutton, the fire must be sharp and brisk. The haunch should be entirely covered with paper till half an hour before it is to be served, when the paper should be removed, in order that the browning and frosting may be effected. The haunch is usually served with currant jelly, mutton gravy in a tureen, and with broccoli sprouts or spinach; the knuckle is usually ornamented with white paper cut in strips.

4867. *Saddle of Mutton, roasted.*—Saddle is one of the most favourite joints of mutton. It is always roasted. The fat on its surface is scored in squares; the skin, previously separated from the fat by the butcher, is generally skewered on by the cook as a preservative of the fat, but which is removed in time to froth and brown the surface. The juice of the meat that flows on carving is by many esteemed as the best gravy; but it is usual to have a tureen of mutton gravy and some jelly sauce served with the joint.

4868. *Loin of Mutton, roasted.*—Done as the last.

The Neck, dressed as Venison.—Have a neck of good four or five years' old Southdown wether mutton (cut long in the bones) hung for nearly a week. Two days before dressing it, pound together a quarter of a pound of allspice and the same quantity of black pepper, and rub the mutton well with it twice a day. Then wash away the spice, cover the meat with coarse paste, and roast it, as directed for venison. Serve with it mutton gravy and currant jelly.

The neck roasted, and served with mutton gravy and boiled spinach, is a very good dish.

4869. *Broiled Mutton Chops.*—Cut the chops from either the loin or the best end of the neck, trim them neatly, and take off some of the fat if requisite. Pepper them lightly; put them on the gridiron over a clear fire. Turn the chops three or four times with a proper pair of tongs. When sufficiently done, remove them to a hot water dish, sprinkle a little salt over them, and lay upon them a few small bits of butter. One of the principal points to be observed in dressing chops and steaks is the sending them hot to table. Mutton gravy in a tureen is sometimes also served.

4870. *Fried mutton chops* are generally inferior to broiled, though, if done well, they do not differ much. After turning the chops in the pan frequently, remove them to a hot dish, and pour away the liquid fat in the pan; boil up in it a few table-spoonfuls of broth or warm water, with a table-spoonful of mushroom catsup, or any other flavouring sauce; and when hot pour it into the dish with the chops, or serve it in a sauce tureen.

4871. *Mutton Chops in disguise.*—Sprinkle each chop with pepper, salt, and chopped parsley, and roll them separately in white paper, of which the inside must be buttered; close the ends of the paper securely, and fry the chops until they appear brown. Do not disturb or break the papers, but let all the fat of the pan drain from them before put-ing them on the dish; cover them plentifully with parsley fried crisp, and send in a tureen some good mutton gravy flavoured with mushroom catsup.

4872. *Maintenon Chops.*—Cut and trim some mutton chops of an equal thickness; rub them over with butter, and cover them with a mixture of eschalots, parsley, and sweet herbs, chopped fine; fry them gently till three parts done, take them from the pan, and let them cool; then rub them over with egg, some more of the herbs, if sufficient does not adhere to them, and over all sift a few bread crumbs. Put each chop into a separate oiled paper, and broil them over a slow fire. For sauce, heat some of the liquor in which they have been fried, the fat being removed, with an equal quantity of veal gravy, and, when quite hot, remove it from the fire, and add some lemon juice or strong vinegar. They may likewise be eaten with whole capers, with some of the vinegar in which they are preserved, with a little Cayenne.

Subsect. 4.—*Lamb.*

4873. *Leg of Lamb, boiled.*—Cover it with cold water, and when it boils scum it. When the scum ceases to rise, set the kettle to keep it only gently simmering for an hour and a half or two hours, according to the size. It may be served with parsley, or with gooseberry sauce and spinach, broccoli, or cauliflower. The loin is sometimes cut into chops, fried, and put on the dish, round the boiled leg, garnished plentifully with crisp parsley.

4874. *Leg of Lamb, stewed.*—Put it into a stew-pan and cover it with mutton gravy, a bunch of sweet herbs, some pepper, salt, and beaten mace; stew gently for three quarters of an hour. Pour out the liquor and cover the meat close to keep it hot, while the gravy is prepared by straining it, thickening it with flour and butter, and flavouring it with mushroom catsup or a few mushrooms, as well as some lemon juice; the whole boiled together must be poured over the lamb when it is dished.

4875. *Lamb Chops stewed with Cucumbers.*—Fry the chops of a light brown, and stew them for half an hour in good gravy; thicken and flavour the gravy, and add to it some cucumbers thickly sliced and previously stewed. Boil them up together, and put the cucumbers first on the dish, the chops on them.

4876. *Roasted Lamb.*—Either quarter of lamb in roasting is papered and frequently basted with beef suet or beef dripping until an hour before it is to be served, when the paper must be removed, and the meat basted with butter, and afterward frosted. Neither lamb nor veal is agreeable when underdone; neither should be taken from the fire until the gravy which drops from it appears perfectly colourless. The time for roasting a fore quarter of 10 lbs. weight will be two hours. A hind quarter of the same weight, two and a half hours. The fore quarter may be improved by the cook cutting off the shoulder and lifting it up with a fork, throwing underneath it some pepper, salt, a small slice of butter, and a squeeze of the juice of lemon or Seville orange; then neatly replacing it. Roasted lamb is served with green mint sauce and salads; also asparagus, pease, and spinach are considered as its suitable accompanying vegetables.

4877. *Broiled Shoulder of Lamb.*—First roast the shoulder till it is more than half done, and let it become quite cold; then score it to the bone, especially in the thicker parts. If it were scored while hot, all the gravy would be discharged, and the dish rendered dry and insipid. Mix up some butter with the yolk of a raw egg, chopped parsley, and a little black and Cayenne pepper, with a tea-spoonful of soy, and introduce this into the parts that have been scored. Place on it the gridiron over a clear fire, and allow each side about a quarter of an hour. When in the dish, have ready two pickled cucumbers coarsely chopped, and a table-spoonful of whole capers; strew these equally over the lamb, and, at the same time, pour over it the following sauce: Incorporate some butter and flour over the fire till it acquires a fine brown, work it into a minced eschalot, and moisten it with strong gravy. When it has acquired the proper consistence, it is finished.

4878. *Lamb Chops from the Loin.*—Trim them neatly, and season them with very little pepper; add to some grated bread marjoram, thyme, parsley, and lemon peel, all finely chopped; having wetted the chops with the yolk of egg, cover them with these mixed, and fry them in butter of a light brown. On serving the chops, garnish them with crisp parsley.

Subsect. 5.—*Pork.*

4879. *Boiled Pork.*—If a leg of pork is bought ready salted, observe whether the knuckle is slit; if it be, the "Cook's Oracle" warns against purchasing it, as in all probability the juices of the meat will thereby have escaped into the pickle.

Pork requires a fuller allowance of fire in cooking than any other meat; if underdone, it is disagreeable and unwholesome. After boiling it, according to the allowance of a quarter of an hour's time to a pound of meat, allow a full half hour beyond that time. If the pork be allowed to soak in cold water for half an hour before it is put into the kettle, its colour will be improved. The boiling should be moderate; fast boiling hardens it. When the meat is taken out of the kettle it should be laid on a dish, that all particles adhering to it may be scraped off; it must then be removed to a hot dish, and served with pease pudding, parsnips, or mashed potatoes.

Pease pudding is considered to be a very oldfashioned accompaniment of boiled pork, but it is one more generally liked than any other.

There are many other parts of porkers which are salted and boiled; the *hand*, the *flank*, and the *neck*.

4880. *Roasted Leg of Pork.*—A leg of eight pounds will require about three hours' roasting. Score the skin in narrow stripes, and, if approved, transversely also; stuff the knuckle with sage, onion (minced small), grated bread, and a seasoning of pepper and salt: rub some salad oil over the skin with a brush or feather, and do not at first put it too near the fire, which would blister the skin. The *crackle*, as the roasted skin is called, should be crisp and brown: the oil will cause this crispness, and give the crackle a better colour than if dripping were used as a basting. Apple sauce is uniformly served with roasted pork.

Roasted loin, neck, and sparerib are dressed as the last.

4881. *Roasted Griskin.*—In a griskin there are several nice pieces, but also some that are hard and dry, therefore, instead of roasting it like the sparerib, boil it up quickly in water sufficient to cover it. As soon as it boils, take it out, dry it carefully, rub butter over it, flour it well, and put it into a Dutch oven before a brisk fire: a few minutes will brown it, when serve it with apple-sauce, like other roasted pork.

4882. *Rolled Pork.*—Bone a neck of pork; have in readiness a forcemeat of chopped sage, bread crumbs, allspice, salt, and pepper; put this forcemeat within the meat, and roll it up lightly. Roast it gently, putting it at first some distance from the fire; froth it with butter, and flour a few minutes before it is served.

4883. *Pork Chops.*—Take some chops from the loin or neck of pork; after peppering, broil them, turning them frequently. When nearly done, throw a little salt on them, and rub on some butter. If eaten in perfection, it must be immediately on their being taken from the gridiron.

4884. *Broiled Blade-bone.*—This is taken from a bacon pig: it is generally broiled, as above described, but is seasoned with a tea-spoonful of made mustard, as well as with pepper and salt.

4885. *To roast a Porker's Head.*—Choose a fine head, clean it well, and stuff it with sage and bread; tie it up tight, roast it like a young sucking pig, and serve it with the same kind of sauce.

4886. *To cook a sucking Pig.*—Let the pig be, if possible, fresh killed; after the first day it loses every hour it is kept some of the firmness and flavour of the meat. Baked sucking pig is better than roasted, because every part is then equally done; but if it be inconvenient to bake it, then it will be requisite, while roasting it, to shelter for a time the middle part from the fire. A pig-iron hung before the middle of the bars, and the fire kept fiercest at the sides, will be the best protection; or if a pig-iron be not at hand, a common flat-iron may be used as a substitute. For *stuffing*, take five ounces of grated stale bread, two ounces of powdered sage, and a large onion chopped fine; season these with pepper and salt, and mix them together with an egg. After filling the inside with this stuffing, sew it up, and lay it before a clear, brisk fire; baste it with salad oil. Remove the pig-iron from the centre when about half done. According to the size and age, a sucking pig requires to be roasted an hour and a quarter or an hour and a half. Before taking it from the fire, cut off the head, and divide it into two parts; cut also the body down the middle into two parts; chop the brains and some boiled sage leaves finely; mix them with either veal or beef gravy. Lay the two sides of the pig back to back on the dish, and garnish the sides and ends of the dish with the split head and the two ears. Serve the gravy in a tureen.

4887. *Pork Sausages.*—Sausages are made from a bacon pig. In making sausage meat, the art consists in chopping it finely, and in flavouring it agreeably with a mixture of crumbled sage leaves, pepper, and salt. If the meat so chopped be not put into the skins taken from the pigs, it may be potted down in a jar and covered. When any part is to be used, it must be rolled up in balls and fried in butter. Pork sausages are usually served with roast fowl or turkey; if alone, they are sent up on a toast, on mashed potatoes, or on stewed red cabbage.

4888. *Oxford Sausages.*—Chop small a pound of lean pork, with an equal quantity of veal, and three quarters of a pound of beef suet. Steep in water a penny roll, and, with sage, pepper, and salt, mix it with the mince; roll it in balls, and fry them of a light brown, or enclose some of it in a light paste in the form of puffs, which must be baked.

4889. *Chawl, or Pig's Cheek.*—Cut off the snout, clean the head, and divide it; take out eyes and brains, and sprinkle the head with salt; let it drain for twenty-four hours. Mix to half a pound of salt half an ounce of saltpetre, and rub the head with it. Let it lie in this pickle for eight or ten days, rubbing it for the first few days, and turning it daily afterward. It may then be cooked, or hung up near a hot chimney to dry, or smoked as bacon. Before it is cooked, it should be soaked in water for some hours, provided it has been dried, otherwise it will not require it. An hour and a half of slow boiling will be sufficient to cook it.

4890. *Ham, to boil.*—If a ham be highly dried, it will require twelve hours soaking in cold water; then scrape it with a knife till clean and free from rust. Set it on in cold water, and after it boils, and the scum has been removed, let it simmer for four or five hours. When boiled, the skin must be peeled off and the ham be glazed, or have raspings of bread sifted over it.

4891. *To boil Bacon.*—If highly dried, soak it for an hour or two, changing the water once; then pare off the rusty parts, and trim it on the under side; scrape the rind clean, put it into the pot, cover it with cold water, and boil it gently for an hour; if more than three pounds in size, an hour and a half. Remove the skin before it is dished, sprinkle over it some rasped crust of bread, and put it for a few minutes before the fire.

SUBSECT. 6.—*Venison.*

4892. *Haunch of Venison, roasted.*—One of buck venison, weighing from twenty to twenty-five pounds, will require four hours and a half roasting; *doe venison*, weighing from fifteen to eighteen pounds, three hours and a half; it is better to have it under than overdone. To preserve the fat, cover the haunch, especially where the fat lies, with white paper, buttered, and over this lay a paste of flour spread upon coarse paper, previously rubbed with dripping to prevent it being scorched. Fasten this last covering over the whole of the haunch with string; baste the joint as soon as it becomes warm, and continue to do so, that the covering may not take fire. About twenty minutes before it is done, cut away the strings and remove the covering; empty the dripping-pan from the first bastings, and put some butter into it, to baste the haunch with after it has been lightly dredged with flour. Garnish the knuckle with white paper cut with a ruffle. Serve it with unseasoned mutton gravy and currant jelly, either cold or melted over the fire, and send it up in a tureen. In the autumn, French beans are served with venison.

4893. *Neck or Shoulder of Venison, roasted.*—These having less fat than the haunch to be preserved, they need not be covered with paper, and they require less time before the fire. When a spit is used, pass three small skewers through the neck, that the spit may be passed on the outside instead of through the joint.

4894. *Stewed Venison.*—Bone and beat a shoulder of venison in order to make it tender. Soak some slices of mutton fat for a few hours in port wine, and lay them on the under side of the shoulder. Sprinkle on them some pepper and finely-powdered allspice. Then roll up the shoulder with the slices within, and tie it tightly together. Put it into a small stew-pan, and cover it with a weak mutton or beef broth, and half a pint of port wine. Cover it closely, and simmer it as slowly as possible for four hours. When done, open it, and lay the meat flat on a dish. Strain the gravy over it, and serve it with currant-jelly sauce. Very fat venison should not be thus dressed, but in some mode less rich.

4895. *Hashed Venison.*—Cut into slices underdone venison, and put them into a stew-pan. Roll up half a pound of fresh butter in flour, and put it with two eschalots, finely chopped, into another stew-pan over a slow fire for about ten minutes. Then add to it half a pint of port wine, a pint of veal stock, and some venison gravy, lemon peel, salt, Cayenne, and one squeeze of lemon juice. Boil all these together for a quarter of an hour, and put it to the slices of venison. Simmer the whole together for ten minutes, when it will be ready to serve.

4896. *Venison Chops.*—Divide a neck of venison into chops, trimming and boning them. Of the bones make gravy. Fry the chops of a light brown, and put them, when done, on a hot dish, while a gravy is made for them in the pan, consisting of a few spoonfuls of that made from the bones, with an ounce of butter rolled in flour. Stir this all together in the pan until it becomes brown and begins to thicken. Add to it half a pound of sifted loaf-sugar, a wine-glass of port, and a squeeze of lemon juice. Made hot in the pan, and of the consistency of cream, it is poured over the chops and served.

SECT. II.—POULTRY AND GAME.

SUBSECT. 1.—*Poultry.*

4897. *Boiled Fowls.*—Choose white-legged fowls for boiling. Poultry loses weight in boiling, owing to the boiling water extracting from them a considerable portion of nutritious matter. For this reason, put no more water to them than will barely cover them. If they are boiled in veal stock, the nutriment extracted from them will be less than if boiled simply in water. The veal broth gains something in strength, and may be afterward employed as soup or stock. Never boil poultry in cloths; prefer to secure their good appearance by carefully scumming. Accompaniments of boiled fowl: ham, bacon, tongue, and turnips; oyster sauce, parsley and butter, or liver sauce.

4898. *Roasted Fowls.*—The art of roasting poultry in perfection depends much on the management of the fire. If the fowls are placed too near they will be scorched and blistered, which lets out the natural gravy, and leaves them dry and insipid. Put buttered paper over the breasts, which is to be removed before they are done, that they may acquire a fine brown. Baste them with butter as soon as they are put down. Roasted fowls require gravy. By some they are eaten with egg sauce.

4899. *Fowls roasted in Batter.*—Bone the fowls and stuff them with a ragout, and their breasts with a force, lard or not; or simply roast the fowls, without forcing or larding. Put the boiled gizzard and blanched liver under each wing; they should not be papered, as they must be brown. When half roasted, baste them with batter till a surface is formed of nearly an inch in thickness. When crisp and brown, serve them on a sauce piquant.

4900. *Broiled Fowl with Mushrooms.*—Slit the fowl down the back; and in the thicker parts, as the thighs and breast, score it to the bone, that it may be equally done. Brush over the inside and places where it is scored with some catsup, then pepper it and broil it over a clear fire. When it is done, have ready the following sauce to pour over it: Melt some butter and flour, and when it becomes of a fine brown, moisten it with a spoonful of veal *consommé* and two spoonfuls of cream or milk; work it well together, add a little Cayenne; and a couple of minutes before you remove it from the fire put in the pickled button mushrooms. Lemon, if approved, may be added at table. Instead of the mushrooms, some persons substitute capers put whole into the sauce.

4901. *Boiled Turkey.*—The same directions as for boiling fowls apply to this bird, and it will only be necessary to show how to prepare the forcemeat with which it is to be stuffed. Beat in a mortar a slice of ham that has been boiled, fat and lean together, or slices of boiled tongue pared, with some of the fat and kernels; pound them into a smooth paste; scald some crumbs of bread with hot milk, and afterward drain the milk entirely from it; add chopped parsley, a little eschalot, and some grated lemon peel, pepper, and salt. Incorporate all these well together, with the yolk of one egg and the whites of nearly two. Introduce this stuffing under the skin of the breast, and confine it from passing out. Prepared in this manner, it will not crumble when brought to table, but cut firm. Boil it for an hour and a half or two hours, according to the size. The usual accompanying dishes are, ham or tongue, oyster, celery, or liver sauces.

4902. *Roasted Turkey.*—The same directions as for roasting fowls apply to turkey. For the previous management, let it be emptied and picked a few hours after it is killed, and introduce into the belly some parings of fresh truffles, or dried, if the fresh are not to be procured; afterward stuff the belly with clean hay, and let the turkey hang by the legs for a week before it is dressed. When the hay is withdrawn, collect the truffle parings, and wash them in warm water, and put a portion of them to stew in the gravy that is sent up with the turkey. For the stuffing, sausage meat, beat together with yolk of egg, is most proper, or, if you prefer it, the same as directed for boiled turkey. According to the size, roast from an hour to an hour and a half. Serve with gravy and bread sauce in tureens, sausages, ham, &c.

Another Way.—If a turkey be large and coarse, cut off the legs below the knee, take off the head, cook the gizzard entirely, and blanch the liver if not larded. Rub the breast with lemon juice, and cover it with slices of peeled lemon; over these lay slices of bacon. Wrap the turkey in paper, and prepare a clear, brisk fire, to which lay the turkey, though not too near till heated through, then bring it nearer. Remove the paper and coverings a quarter of an hour before it is done; brown it highly, and frost it. Dish it over plain gravy into which a slight flavour of garlic has been given. Garnish with Bologna sausages, and with curled bacon, cresses, lemon, &c.

4903. *Boiled Goose.*—Singe a goose well, pour over it a quart of boiling milk; let it lie in this a whole night; take it out and dry it well; cut into small pieces a large onion and some sage; put it into the goose, and close the openings in the usual way. Put it into a pot of cold water, let it boil gently for an hour, covered very close. Serve with onion sauce.

4904. *Green Goose, roasted.*—This is not stuffed, as the Michaelmas goose, with sage and onion, but has merely some pepper, salt, and a lump of butter put into the inside. Baste it with butter, and froth it well. Serve with a good gravy in the dish, and a green sauce in a tureen. Three quarters of an hour is sufficient time for roasting it.

4905. *Roasted Goose.*—Let it be stuffed with sage and onion, finely minced and well peppered. Roast it with an equal fire, and when the fat begins to drop it will only require occasional basting. Send up good gravy free from fat, and also a sauce composed of two tea-spoonfuls of fresh-made mustard, half a tea-spoonful of salt, sufficient Cayenne, and a large glassful of port wine.

4906. *To roast Ducks.*—For the stuffing, boil together one ounce of onion, and half an ounce of green sage; chop them very small, and mix them with a breakfast-cupful of bread crumbs, with butter about the size of a walnut, and a little black pepper and salt. Bind these together with the yolk of an egg, and stuff with the mixture one of the ducks about to be cooked. There are many persons who object to the flavour of onions. The time for roasting ducks must be varied, according to their size, from half to three quarters of an hour. The feet, crisply roasted, are considered by some persons as dainties. A good meat gravy in one tureen, and sage and onion sauce in another, are usually served with ducks, as well as green pease.

Roasted ducklings are never stuffed with sage and onion, but are roasted from a quarter of an hour to twenty minutes, during which time they ought to be carefully basted with butter and frothed.

4907. *Pigeons.*—Roasted pigeons require a brisk fire, and to be well done, but still to afford gravy when cut into. Let them be roasted with stuffing in the belly, prepared in the following manner: Take the hearts and livers of the pigeons, and nearly double the quantity of the fat of ham or bacon, beat them in a mortar to a smooth paste; moisten some crumbs of bread with milk, and press out the milk through a napkin; add chopped parsley, grated lemon peel, black pepper, and salt; unite these with white and yolk of egg beat together, divide this into equal portions, and stuff the pigeons. As these birds possess hardly any fat, they are to be often basted with butter while roasting. For sauce to them, melt some butter with a little flour, moisten with veal consommé, and stir in some chopped parsley; pour this over the pigeons, previously sprinkling them with a little salt. The same sauce is used for broiled pigeons.

4908. *Broiled Pigeons.*—Clean the pigeons well, split the backs, pepper and salt them; broil them quickly over a clear fire, and pour over them a sauce of stewed or pickled mushrooms in melted butter. Serve them as hot as possible.

4909. *Stewed Pigeons.*—Make a stuffing with pigeon livers parboiled and bruised in a mortar; add to them bread crumbs, butter, pepper, salt, pounded cloves, parsley, sweet herbs chopped small, and the yolk of an egg; fill the pigeons and tie them up at both ends. Half roast or fry them; put them into good gravy or beef broth, with an onion stuck with cloves, a bunch of sweet herbs, and a slice of lemon. Let them stew *very gently* for twenty minutes; strain the same and skim off the fat; add to it pickled mushrooms, hard yolk of egg balls, and forcemeat balls. Larding the pigeons improves them.

Subsect. 2.—*Wild Birds and Game.*

4910. Wild birds, being less fat than domestic fowls, require more copious and frequent basting with fresh butter. Also, after they are killed, they require longer keeping. When the colour of a bird begins to change near the vent it is time to dress it.

4911. *In roasting pheasants or partridges,* make a clear fire, but not too fierce. Thirty minutes will be a sufficient time for a young bird to roast; forty, or even fifty, for a full-grown pheasant, and twenty for partridges. Game is spoiled if overdone. As an improvement to the flavour of pheasant, "The Cook's Oracle" recommends a piece of beef steak to be enclosed in it, and roasted with it. Serve both pheasant and partridge with a clear, brown gravy of beef, and with bread sauce.

4912. *Broiled Partridges.*—Partridges broiled are quickly done, and are excellent. Cut them in half, and trim them neatly. Dip them in butter melted previously, and cover them thickly with bread crumbs. About a quarter of an hour before they will be wanted broil them over a clear, brisk fire, and serve them with sauce, *à la Diable*. See "Sauces."

4913. *Moor game, grouse, and black cock* are all dressed like partridges. The black cock will require as long a time roasting as the pheasant; moor game and grouse, as the partridge. Serve them with currant jelly and fried bread crumbs.

4914. *Woodcocks* are never drawn, and the entrails add much to the flavour of the bird. Cut as many slices of bread as there are birds, and toast or fry them of a delicate brown. Put them in the dripping-pan under the birds, so as to catch the "trail" which, as the roasting proceeds, drops from them. Roast them for twenty minutes, and baste and froth them with butter and flour. Put the toast on a hot dish, and lay the birds on it. Pour a very little but good gravy in the dish, and send up more in a tureen. Garnish with lemon.

4915. *Wild ducks* should be stuffed with seasoned sage and onion, and roasted before a clear fire, and basted, so as to abound with red gravy; they should then be carved, put into a covered silver dish heated with a spirit lamp, and gently stewed about five minutes in strong, clear gravy, with some Cayenne pepper; an instant before the lamp is blown out add a table-spoonful of lemon juice. Serve it up very hot.

4916. *Widgeons and teal* are dressed as wild duck, but require less time in roasting; not more than ten minutes for the widgeon, nor more than seven or eight for teal. Pour a good gravy over widgeons, and serve with eschalot sauce in a tureen.

4917. *Snipes* differ little from woodcooks except in size; they are dressed in the same way, but require about five or seven minutes less in roasting. Serve with orange gravy sauce.

4918. *Larks and plovers* require simply to be roasted on a small bird spit, and to be served up with gravy and fried bread crumbs.

4919. *Roasted Hare.*—A hare is dry meat, requiring abundance of stuffing, gravy, and sauce to render it palatable. But the common practice of soaking in warm water previous to dressing it is injudicious. Prepare the stuffing in the following manner: parboil the liver in a little salt and water, and beat it in a mortar with a slice of fat ham boiled. When beaten to a smooth paste, add some bread crumbs, chopped parsley, thyme, and marjoram, grated lemon peel, and a little black and Cayenne pepper. Incorporate these with an egg well beaten. Put the whole within the body of the hare, and sew up the skin. When the hare is laid to the fire, put into the dripping-pan three pints of milk, and constantly baste the hare with it for three quarters of an hour. The rest of the time baste it with butter; and before it is taken up, froth it highly by dredging it with flour, and basting it a few times longer. It will require an hour and a half's roasting, unless it be very small. Serve it with gravy and melted currant jelly.

4920. *Rabbits, boiled.*—Put them into a pan of warm water for ten minutes; then boil them for twenty minutes, or half an hour if they are very large; if they appear to be old, they will require nearly three quarters of an hour's time to boil them sufficiently. Smother them with white onion sauce, and with the liver minced garnish the dish, unless the liver be required to chop and mix with the sauce.

4921. *Rabbits, roasted.*—Young rabbits will require to roast for thirty minutes; old ones nearly forty. They are stuffed like hare, and should be dredged with flour and basted with butter. The liver, boiled and chopped with parsley, must be put into melted butter and served in a tureen.

4922. *Rabbits to be broiled* are split down the middle, and laid flat on the gridiron; the inside being previously seasoned with pepper and salt. Liver and parsley, and butter sauce, or a grill sauce, is usually served with them. Part of the liver is sometimes removed to garnish the dish alternately with slices of lemon.

SECT. III.—FISH.

SUBSECT. 1.—*Sea Fish.*

4923. *Boiling Turbot.*—M. Ude says, "I have ascertained, by many years' observation, that a turbot kept two or three days is better than a very fresh one." If it is to be kept, let it be drawn, washed, rubbed lightly with salt, and laid on ice or sand in a cool place. An hour before it is to be dressed, soak it in water with some salt in it. Score the skin across the thickest part of the back, to prevent it breaking on the breast, which will happen if this precaution be not observed, by the swelling of the fish. Put into a fish-kettle of cold water a large handful of salt, lay the fish on a drainer in it. When coming to a boil, skim it, and afterward set the kettle on the side of the fire to boil as gently as possible from 15 to 20 minutes. *Fast boiling* will break the fish to pieces. This allowance of time is for a fish weighing from 8 to 9 lbs. Rub through a hair sieve a little of the inside red coral spawn of the lobster, to sprinkle over the fish after it is dished. Have a fish napkin properly arranged on the fish drainer, and carefully dish the fish. Garnish it with slices of lemon and finely-scraped horseradish. Serve with lobster sauce. *Turbots* are sometimes garnished with fried smelts, or fried gudgeons, laid so as to form a fringe round the turbot. A sole cut into strips and fried is also occasionally served with turbot.

4924. A turbot kettle should be 24 or 25 inches long, 22 wide, and 9 or 10 deep. Fish requires more cooking in cold than in hot weather.

4925. *Broiled Turbot.*—It is both difficult and inconvenient to broil a large turbot. A small one succeeds much better, or slices of a large one detached from the bone. When dressed in this manner it must be previously *marinated*, that is, soaked in sweet oil with salt and pepper. The broiling should be conducted slowly over a clear fire. It may be served up with chopped capers and melted butter, or with Dutch sauce.

4926. *Brill* is dressed and served in the same way as boiled turbot. It is a delicately flavoured fish. Any other mode of cooking it could not improve its flavour; even sauces, if strong, are too overpowering accompaniments.

4927. *Cod's head and shoulders* should be tied up closely and put into cold salt and water sufficient to cover it entirely. It will require from fifteen to twenty minutes' boiling, or longer if very large. Great care must be taken to serve it without any speck of scum. Garnish it with horseradish and walnut pickle, and with the melt, roe, and liver. *Fried smelts* are sometimes added. Oyster, or shrimp and anchovy sauce, scollops, and scolloped oysters are sometimes sent up with it.

4928. *Crimped cod* may be either boiled, fried, or broiled.

4929. *Baked Cod.*—Open and clean the fish well, and put in the inside a stuffing made of two ounces of beef suet, some chopped parsley and sweet herbs, an egg, and pepper and salt, nutmeg and grated lemon peel. Sew up the fish when stuffed, enclose it in a buttered paper, and put it in a dish into the oven; baste it occasionally, while baking, with melted butter.

4930. *Salted cod* must be well soaked in cold water for one or two nights before it is used; each day taking it from the water and putting it into a cold place. The Doggerbank cod are reckoned the best. They cut into large flakes, and are not stringy, like the north country cod, which have been longer salted. Salted cod must be put into a kettle with cold water, and simmered, not boiled. If the water boils, the fish will be hard and thready. It is served with egg sauce, parsnips, or mashed potatoes, and garnished with hard-boiled eggs cut in quarters.

4931. *Cod Sounds, boiled.*—Soak them in warm water half an hour, then scrape and clean; and if to be dressed white, boil them in milk and water: when tender, serve them in a napkin with egg sauce. The salt must not be much soaked out, unless for a fricassée.

4932. *Cod Sounds, broiled.*—Scald them in hot water, and rub them well with salt; pull off the dirty skin, and put them to simmer till tender; then take them out, flour and broil them. While this is being done, season a little brown gravy with pepper, salt, a tea-spoonful of soy, and a little mustard. Give it a boil with a bit of flour and butter, and pour it over the sounds.

4933. *Boiled Haddocks.*—Put them into cold water with some salt in it. When the water begins to boil draw them away from the fire, and allow them to simmer for ten minutes. Strain them well from the water, and serve with anchovy sauce. Garnish with horseradish and lemon.

4934. *Fried Haddock.*—Skin the fish, and cover it with egg and bread crumbs seasoned with salt and pepper. The pan should be moderately hot, with boiling lard or butter.

4935. *Baked Haddock.*—Fill a haddock with a stuffing of bacon, beef suet, sweet herbs chopped fine, bread crumbs, and an egg to bind these ingredients together. Chopped oysters and a tea-spoonful of anchovy catsup will improve the stuffing. Sew up the fish, cover it with bits of butter, and bake it for half an hour.

4936. *Whitings* are often used, when fried, as a garnish to salmon and cod, and are then skinned, curled, with the tail entering the mouth, and fried in lard or butter. If they form a dish by themselves, they are served with shrimp sauce or anchovy essence in melted butter.

4937. *Soles, boiled.*—The largest soles are usually chosen for boiling. After they are well cleaned, rub them over with lemon juice, and set them in cold salt and water on the fire. When they begin to boil, let the water be scummed, then simmer them only, from ten to fifteen minutes, according to their size. Fish should be boiled till the meat separates readily from the bone, and has lost all appearance of redness. An error equally to be avoided is over-boiling fish. If over-boiled, a sole cuts woolly, and has, in fact, lost all its flavour. Serve it with anchovy sauce, and garnish with parsley.

4938. *Fried Soles.*—There is a considerable art in frying fish properly. The great secret consists in employing sufficient lard or oil, and also in not exposing the pan to a too fierce fire, which turns the lard brown or black. Frying is best conducted over charcoal. Before the soles are fried, beat up two eggs with a little salt; and when well mixed, rub some of this over them, and sift on them some bread crumbs. Fry them till they acquire a bright brown. When soles are very large and thick, it is better to divide them into two or three portions, or score them down to the bone. Proceed in the same manner to *fry whitings* (which must be previously skinned), and also flounders, smelts, &c.

4939. *Broiled Soles.*—They must be previously marinated, or soaked in salad oil, with some salt and pepper, and then broiled over a clear fire. When dressed thus, they should be served with anchovy sauce, which is prepared in the following manner:

4940. *Stewed Soles.*—Take the fillets of soles (the fleshy parts on both sides of the fish removed are so named), rub them over with beaten egg, and strew on them, finely chopped, and mixed together, parsley, eschalot, a little thyme, and button mushrooms. When covered with these, roll the fillets round, and retain them in that position with a piece of thread. Fry them of a light brown; drain the fat from them, and keep them hot. The sauce should consist of the yolks of two boiled eggs, pounded with a little butter and flour; dissolve this in veal consommé over a gentle fire, and when of a proper consistence, add some cavice, lemon juice, and Cayenne pepper. Pour this sauce into the dish, and arrange the fried fillets.

4941. *John Dory.*—This fish is best boiled and served with lobster or shrimp sauce; but if brought from a distance, and rather stale, it should then be marinated in oil, salt, and pepper, and afterward broiled; it then requires Dutch, or Quin's sauce, with melted butter.

4942. *Crimped skate* is to be boiled in salt and water, to which some vinegar may be added. When the pieces are of unequal size, the thicker may be put in before the others, that they may be done together. Shrimp sauce is the usual appendage.

4943. *Skate, fried.*—Divide pieces of skate in fillets, and dry them on a clean cloth; beat the yolk and white of an egg thoroughly together, and dip the pieces of fish into it, and then into fine bread crumbs. Fry them in hot lard or oil till delicately brown; lay them to drain on a sieve; garnish with crisp parsley; serve with caper sauce, with an anchovy in it.

4944. *Salmon* must be boiled with the same precaution as directed for turbot. On account of its thickness, it is more equally dressed when split, or cut into moderately-sized pieces. When boiled, it is accompanied with lobster or shrimp sauce. Put some salt into the water; when it boils, take off the scum; boil it very gently. Salmon requires almost as much boiling as meat, viz., a quarter of an hour to a pound of fish; but the *thickness* must be considered.

4945. *Salmon, broiled.*—Cut slices of salmon an inch and a half thick; marinate them in oil, and have a clear fire, and the gridiron rubbed over with lard. Turn the salmon on both sides, as in broiling meat.

4946. *Fried salmon* may be eaten with a sauce composed of finely-chopped eschalots, catsup, and vinegar, highly seasoned with Cayenne. To these, fried smelts, when in season, form an elegant garnish.

4947. *Mackerel* may be plain boiled, but caution must be used that they do not boil too violently, as they are easily broken; when the roes are very large, especially the hard, they will frequently be underdone when the fish are sufficiently: a small aperture made in the belly, with slow boiling, will remedy this inequality. They are served up with parsley and fennel sauce. This is best prepared by washing these herbs well, and chopping them unboiled, when they are to be added to the butter while melting, and allowed to simmer for a couple of minutes. In this manner the sauce will be strongly impregnated with the flavour of the herbs, and also come up beautifully green.

4948. *Mackerel, broiled.*—The fish should be split down the back, and a little salad oil be laid on the inner surface with a feather, to prevent it sticking to the gridiron, and to retain the salt and pepper with which it must be seasoned. Serve with parsley and fennel sauce, or with boiled green gooseberries. The acid flavour is given sometimes by the juice of lemon squeezed on the fish at table.

4949. *Fillets of Mackerel, fried.*—Take the fillets of four mackerel, remove the skin, dip them in beaten egg, strew on them some chopped parsley and fennel, and afterward some bread crumbs; fry them. For the sauce, pound the soft roes with some thick cream, which afterward pass through a tamis. Melt some butter with a little flour and some veal consommé, stir in the strained roe and cream, season with salt and Cayenne, and then add some catsup, or a little cavice and lemon juice, and while hot pour it over the fillets.

4950. *Other Ways of dressing Mackerel.*—When mackerel are abundant, choose a dozen with soft roes, which take out and preserve. Six of the fish may be boiled in as much water as will cover them, putting in some allspice, a bay-leaf, whole pepper and salt; when done, take them out and place them regularly in a deep dish. Add a cupful of strong vinegar to the liquor in which they have been boiled, and, while hot, pour it over them. They are to be eaten cold, as pickled salmon. The other six may be nearly split on the inside. Contrive to keep the sides extended by a splinter of wood, and when sprinkled with salt and pepper, let them hang a day in the sun; afterward remove them into the shade. In this state, when brushed over with a little salad oil, they may be broiled and eaten with caper sauce. The reserved soft roes will make patties in the following manner: Pound them with a fourth part of their weight of butter, and add sufficient cream to give them a proper consistence; season this well with salt, black and Cayenne pepper; distribute it into the patties, and gradually bake them.

4951. *Red mullet* are not to be emptied, but broiled as fresh as possible in buttered paper, and served very hot. There is but one sauce for them, and this is made at table by mashing the liver on your plate with some oiled butter, likewise very hot, Cayenne pepper, and the squeeze of a lemon.

4952. *Herrings* must be perfectly fresh; the soft roes are esteemed most delicate. They are to be broiled, and sent to table as hot as possible. Their sauce is melted butter, incorporated with mustard, salt, and pepper. In order to eat them properly, cut off the head and tail, pinch the middle, and at the head part draw out the bones.

SUBSECT. 2.—*Fresh-water Fish.*

4953. *Trout.*—The sooner a trout is dressed after it is caught the better; its firmness is improved by crimping. A large trout should be boiled in salt and water, but not with vinegar, which would destroy the colour. It is served with lobster sauce. Small trout are better *broiled*, but served with the same sauce as the boiled. When trout have been kept for a day or two, they are excellent if marinated, broiled, and eaten with Dutch or Quin's sauce.

4954. *Eels.*—The river eel is always to be selected, as those taken from ponds are muddy, and possess a disagreeable taste. They may be simply boiled, either whole or crimped, and eaten with parsley and butter sauce. Another method is, by placing them to the fire on a steel wire, or fine spit, usually called *spitchcocked* (a term evidently corrupted from spit-cooked). With large eels, which always abound with oil, this is the preferable method, as the oil is drained out by the fire. When done in this manner, they may be served with catsup, anchovy, caper, Dutch, or Quin's sauces. Eels are also fried, when they are to be dipped in beaten egg, and covered with crumbs of bread and chopped sweet herbs. These may be eaten with any of the above-mentioned sauces; but capers, coarsely chopped and served in some of their own vinegar, without butter, is the most appropriate sauce.

4955. *Matelotte of Eels.*—To prepare this dish properly, let the pieces of eel intended for the matelotte be spitchcocked till three parts done. In the mean time, prepare the following sauce: beat a couple of anchovies in a mortar with the yolks of two boiled eggs, a little grated lemon peel, half a tea-spoonful of minced eschalot, and two tea-spoonfuls of chopped mushrooms; moisten this with veal stock, or consommé, till the mixture acquires the thickness of cream. Put this in the stew-pan, with sufficient additional stock to cover the eels, which are to be gently stewed till done. At the bottom of the dish lay pieces of fried bread, moistened with lemon juice; add to the sauce sufficient Cayenne pepper and salt, a glass of port wine, and a table-spoonful of Quin's sauce; pour this over the fish. *N.B.*—If any oily matter extracted from the eels should float on the surface of the sauce, let it be carefully skimmed. For ordinary occasions, eels may be stewed with less trouble and expense by boiling them in little water till three parts done, and employing this liquor as the basis of the sauce; to which may be added some chopped parsley and minced eschalot, a table-spoonful of reduced catsup, sufficient pepper and salt, with some thickening of flour and butter.

4956. *Collared Eels.*—After large eels are skinned, take out the bones; season them on the inside with salt and spices, and strew over them parsley, eschalot, and lemon peel, finely chopped; then roll them up, and bind them tightly with some tape. Stew them till sufficiently done in veal broth; afterward reduce the broth, add some isinglass, two table-spoonfuls of white wine, and the same quantity of vinegar, with a little Cayenne pepper. When the isinglass has dissolved, skim the liquor free from all fat, and clear it with an egg; pass it hot through a strainer, and, when cold, it will be a savoury jelly. Remove the tapes from the eels, and serve them up, surrounded and covered with the jelly broken into pieces.

4957. *Pike* may be plainly boiled, or cut into junks, marinated, and fried. They may be eaten with any sauce.

4958. *An excellent Method of cooking them.*—Take two pikes, weighing from six to eight pounds each; after they are scaled and emptied, dissect out the flesh and bone, leaving the head and tail attached to the skin; pick off the flesh from the bodies of both, avoiding all the small, forked bones, which in this fish are very numerous. When this is done, beat the separated flesh in a mortar, with three anchovies, the yolks of four eggs, and a pound of butter; mix in a good quantity of chopped parsley, some few sweet herbs, minced eschalots, black pepper, and salt, and form the whole into a mass, with sufficient white and yolk of egg. Introduce this into the skin of one of the pikes, and sew it up neatly. Prick the skin in a few places with a sharp fork, and roast it till done before a brisk fire; it will require nearly an hour. Put into the dripping-pan a pint or pint and half of cider, with which it is to be frequently basted, and the remainder of this will be the proper sauce for the fish, with a little Cayenne.

4959. *Perch.*—Like all fresh-water fish, perch may be simply boiled and fried. They are, however, most esteemed when dressed as *water-souchy.* Where perch are abundant, pick out the smallest fish, and when they are cleaned, cut them into pieces, and boil them slowly with some parsley roots, whole pepper, and salt, until you obtain a strong broth. Strain this through fine muslin, pick out the parsley roots, slice them, and return them to the strained liquor, in which the larger perch, previously crimped, are to be boiled. Towards the end of the process introduce a few bunches of parsley that have been scalded in salt and water to preserve their green colour. They require no sauce, the broth being, with the addition of some salt and pepper at table, fully sufficient. Serve them in a deep dish, and send up with them slices of brown bread and butter.

4960. *Flounders* are prepared in the same manner as water-souchy.

4961. *Carp.*—Carp, though occasionally simply boiled and served with a sauce of anchovy, parsley, and butter, is considered to be a fish requiring stewing in rich gravy to make it worthy of a place on the table. It must be first carefully cleansed through a small opening made in the belly without damaging the scales. The gills are then taken out, the tongue kept in its place. Place the carp in a kettle that will just hold it, and sprinkle it with hot, red vinegar, to give it a blue colour. Fry with butter, and till brown, two or three carrots, two onions, and some parsley; to these add a bottle of port and half as much water. Tie up a bunch of parsley, a bay-leaf, a sprig of thyme, and some basil. Stew all together for an hour; strain off the gravy, dish the carp on a napkin, and serve it with anchovy sauce.

4962. *Tench* may be cooked in the same way.

Subsect. 3.—*Shell-fish.*

4963. *Lobsters.*—Fill a fish-kettle with salt and water, the proportion of salt being a table-spoonful to a quart of water; when boiling hot, put in the lobster, and, according to its size, boil it briskly from half an hour to an hour. When it is done, wipe off the scum from the shell, and rub over it a little butter or sweet oil. When cold, break off the claws, and crack the shell in each joint, but do not shatter the meat; split the tail down the middle; set the body upright in the dish, and place around it the claws and tail.

4964. *Cray-fish* are boiled in the same manner.

4965. *Broiled Lobster.*—When boiled, split the tail and chine; crack the claws, pepper and salt them; take the body out of the shell, and clear the head of the part called the lady. Replace the body within the shell, then, with the claws and tail, put them on the gridiron; while broiling, baste them with butter, and serve them with melted butter in a tureen.

4966. *Lobster Curry.*—Put the meat of two lobsters into a stew-pan with a blade of mace, four spoonfuls of veal gravy, and four of cream; rub together very smoothly two tea-spoonfuls of curry powder, one of flour, and one ounce of butter; add these, with some salt, to the lobster, and simmer the whole together for an hour; stir gently into the gravy the juice of half a lemon, and serve it.

4967. *Lobster Salad.*—Make a salad of two or three well-washed lettuces, cutting away the stalks, and shredding the leaves moderately. Slice some boiled red beet-root and one good-sized cucumber; wash, and cut in long shreds, four anchovies; add to these some tarragon and chervil, chopped fine. Make a salad mixture of the yolk of an egg (boiled for ten minutes, thrown into cold water, and rubbed with a wooden spoon through a sieve), a table-spoonful of cream, one of sweet Florence oil, a tea-spoonful of made mustard, a little salt, and two table-spoonfuls of vinegar. Put this mixture into the salad bowl, and lay the lettuce upon it (not mixed with it) in the centre, and the meat of the lobster and the other ingredients around it, according to fancy; and, to ornament the whole, rub through a sieve some of the red spawn over it.

4968. *Shrimps.*—Shrimps, in the first instance, are always boiled for ten minutes in salt and water, into which they are not put until it is boiling.

4969. *Stewed Shrimps or Prawns.*—When the shrimps are boiled, remove the shells, and put them into a meat gravy with a small piece of butter, a tea-spoonful of flour, and a seasoning of nutmeg, salt, and pepper. In this simmer them for three or four minutes, and serve them with small bread sippets. If a white dish be preferred, cream must be used instead of gravy.

4970. *To boil Crabs.*—Boil them the same way a slobsters, which see. When cold, crack and empty the shell, in the largest of which mix some vinegar, salt, white pepper, and Cayenne; put the meat to it and mix altogether. Some add a very little sweet oil; but crab, being of itself rich, scarcely requires it.

4971. *Hot Crab.*—The great shell must be left whole for the meat to be served in it. Chop and fry some parsley, mushrooms, or truffles, and a small portion of young onion; mix these with the meat, and fill the shell with them; add a little good gravy, some lemon juice; shake over the surface some flour; brown it with a salamander, or in a Dutch oven. Glaze it, and serve it very hot.

4972. *Stewed Oysters.*—Take a dozen of oysters; strain the liquor from them, remove the beards, and boil them and liquor together to form the stock for the stew. The liquor must then be strained away from the beards, and, being thickened with cream, flour, and butter, it must be again made hot over the fire, the cook stirring it gently the whole of the time. The oysters must then be put into the gravy, and gently warmed (not boiled) for ten minutes. This dish is often served with veal collops.

4973. *Scolloped Oysters.—Take from a dozen oysters* the beards, and boil them in the liquor; which, when done, strain, and reserve to moisten with it the bread crumbs on which layers of the oysters are placed, either in an earthen dish called a *scollop*, or in a real scollop-shell. In laying the fish, season it with white pepper and salt; fill the shells high, and in the form of cones, and brown them with a salamander, or in a Dutch oven. As soon as they are lightly browned, it may be inferred that the oysters are sufficiently cooked. There is scarcely any fish that requires so little cooking as the oyster.

4974. *Fried Oysters.—Grate* some bread, and season it with white pepper; dip the oysters in the crumbs, and have a light batter prepared in which to fry them. These form a pretty garnish to white fish.

4975. *Oyster Loaves.—Warm oysters* in their own liquor, and in which some cream is mixed, thickened with flour and butter, and seasoned with nutmeg and salt. Enclose the oysters in rolls made by pastry-cooks, and which are formed of a very light and short crus .

SECT. IV.—SOUPS.

SUBSECT. 1—*General Observations.*

4976. *Meat soups and gravies* have one basis, formed by boiling together meat and water; the soluble parts of the former uniting with the water, and simmered down to a certain strength, is termed "stock." When this is obtained, it is ready to be employed as the basis of any meat soup or gravy; and the soup receives its name according to the vegetables employed, or of the ingredients used in seasoning it. The proportion of meat to water for stock, from which the richest soups and gravies are to be made, is *two pounds of meat* to a *quart of water.* For more ordinary soups, *one* pound to a quart; for weak broths and meat teas, given to invalids, a quarter of a pound of meat to half a pint of water.

The strength and flavour of the stock may be increased and improved by the addition of all trimmings of meat, poultry, and game, such as the necks, feet, gizzards, &c.

4977. *Soups of meat* should, as much as possible, be made while the meat is *fresh;* in meat long killed the fibres become stiffened, and the juices of the flesh dried up; hence the greater difficulty in extracting them. In country places, in which markets occur rarely more than once in the week, fresh-killed meat cannot always be obtained. In such case, a cook should fry meat intended for soups as soon as she can conveniently do so after it is brought into the house; and this should be done especially in warm weather.

4978. *When it is possible, soups should be made the day before they are wanted.* A second boiling, if the soup is poor, increases its strength by evaporating the excess of water. The fat, too, is more readily skimmed off when soup is cold than when hot; and the fat it is desirable to clear off completely, as it renders soup, if left in it, too rich. Flour dredged on the surface, uniting with the fat, enables the cook to remove a considerable part of it, if there be not time to allow it to cool. But if the soup is to be clear and transparent, there is a danger of thickening it, though slightly, by this use of flour. Dr. Kitchener recommends, in the "Cook's Oracle," another mode of removing the warm fat from soup: that of dipping a *tamis* sieve or clean cloth in cold water, and then passing the soup through it. The cold temperature of the water in the cloth coagulates the fat, which adheres to it, but allows the soup to pass through. After this process, the soup must be warmed again over the fire before it is served.

Hard or fast boiling is, in making soups, to be carefully avoided. It hardens and contracts the fibres of the meat, so that it cannot yield its juices to the water.

Gentle boiling or stewing has a contrary effect; the water gradually warming the meat, has a tendency to relax its fibres, and while penetrating into the meat, extracts from it and carries away with it the finest of its flavours; and if the pot be closely covered, this flavour does not escape with the steam. All soup pots should be closely covered while on the fire; the vapour not being permitted to escape, becomes condensed, and returns to the soup, *whereby* less water is required to keep up the quantity of stock to be made, and, consequently, less meat to keep up its proper strength. Yet still, all stock should be allowed to boil up in the first instance, because the ebullitions send up to the surface the impurities which there may be either in the water or on the ingredients, and which should be carefully scummed off. When these cease to appear on the surface, the boiling of the soup should be moderated, by bringing the kettle off from the strongest heat of the fire, and placing it where it can only gently simmer.

Clear soups are at this period more fashionable than those that are thickened. But whenever the thickened soups are preferred, it is only requisite to incorporate the proper thickening (see " Thickening") with the clear stock.

Seasoning of soups with spices should be sparingly done; generally speaking, Cayenne pepper and salt are the chief seasoning. When other spices are to be added, the following receipts will specify the kind and quantity to be employed:

SUBSECT. 2.—*Winter Soups.*

4979. *Clear brown Stock.*—Take beef; after washing it well and cracking the bones in two or three places, add to it any trimmings of meat, poultry, and game, and cover the whole with cold water. Set the pot over a moderate fire, and keep stirring the meat from the bottom as the water begins to warm. When it boils, remove the scum and throw in a tea-cupful of cold water, to make more scum rise. The excellence and clearness of the soups and gravies made from this stock will depend upon its clearness. It must be as limpid as water. When it has been skimmed completely, add one carrot, two turnips, a head of celery, and one onion. There must be neither sweet herbs, garlic, nor spice added. Stock must not have any flavour given to it, which might interfere with its general uses: in forming soups and sauces out of it, any required flavour may be then added. Now cover the pot *closely*, and set it *by* the fire to *simmer* gently for four or five hours; strain it through a hair sieve, or tamis, into a clean earthen pan, and set it in a very cool place. The meat thus stewed will be found still sapid and nutritious, capable of being converted into a savoury dish; or it may be potted, or again put into water and boiled four or five hours more to yield a second stock.

4980. *Second Stock, or Consommé* (see " *French Cookery*").—This is a more concentrated stock than that described in the preceding receipt. Prepare it thus: Lay at the bottom of a stew-pan slices of ham or bacon, over these a layer of sliced beef; or, if to be drawn white, slices of veal instead of beef; to these add some parsley and green onions, with trimmings of poultry and game, and moisten the whole with a little of the first stock. Put the stew-pan over a slow fire, care being necessary to keep the stock from burning or from acquiring a high colour. When warm, score the meat with a knife to let out the gravy, and fill up the pan with first stock. Simmer the whole for three hours, keeping on the cover, except when it is requisite to take off the scum and fat. While hot, strain it into a clean earthen pan, and set it in a cool place.

By longer simmering this stock may be converted into *glaze*.

4981. *Thickening for brown Gravy Soups.*—Materials for thickening soups may be either *bread, bread-raspings, isinglass, potatoes, pease, carrots, flour,* or *barley*. Whichever is employed must be simmered gently with the soup until incorporated with it. The whole should be afterward passed through a sieve to remove any lumps of the thickening ingredient.

A thickening which may be kept for a fortnight, or even more in cold weather, may be made by boiling half a pound of clarified butter with as much fine flour mixed in it as will make it of the consistency of a flour and water paste. The boiling of these together must be continued until the mixture becomes of a gold colour; then it must be poured into a clean earthen pan, and put into a cool place. If this be boiled over a very quick fire it may acquire a burned taste, which would spoil its flavour, as well as that of soups thickened with it.

4982. *To clarify Stock.*—If the soups and gravies to be formed out of stock are to be clear and transparent, it should first be clarified. For this purpose, two eggs, the shells, whites, and yolks together, must be pounded, and then added to the soup to be boiled in it for about ten minutes. The whole must then be poured through a tamis, or a fine sieve. Two eggs will clear three quarts of soup. It is to be observed that Dr. Kitchener considers this mode of clearing soups as less effectual than that of carefully scumming them when boiling, as recommended above.

For portable soups, see Book X., " Preservation of Food."

RECEIPTS FOR SOUPS.

4983. *Ox-cheek Soup.*—Break the bones and wash the cheek thoroughly; put it into a large stew-pan with two ounces of butter at the bottom; let the fleshy part of the cheek be downward; add half a pound of lean ham cut in thin slices, four heads of celery, three large onions, two carrots, one parsnip (all sliced and cut small), three blades of mace. Put the stew-pan over a moderate fire for a quarter of an hour; then put in four quarts of warm water, and let it simmer till reduced to two; take out the head and strain off the soup clear from the vegetables, and use a little browning to improve the colour; add the white part of a head of celery cut small and previously boiled; scald two ounces of vermicelli, put it to the soup, and boil all together for ten minutes; pour it into the tureen over a French roll, and serve it.

4984. *Ox-tail Soup.*—Divide two ox tails into separate joints, and lay them to soak in warm water to extract the blood; then put them on to stew gently in a quart of water and a pint of beef stock; when they begin to boil, remove the scum and introduce the vegetables, which are to consist of four moderately sized onions, in one of which stick half a dozen cloves and a few corns of black pepper, two turnips, and a large carrot sliced, a head of celery, sweet herbs, a bunch of parsley, and a piece of lemon peel. Let all these stew together until the tails are sufficiently tender, when they are to be picked out and reserved. To the remaining liquor and vegetables add two quarts of beef stock, and let them continue to simmer about an hour; then strain the soup and remove all fat; now put in the tails, and boil gently for twenty minutes; a little before you remove it from the fire, add a wine-glassful of port wine and one of catsup, with salt and Cayenne pepper. *N. B.*—Always rather under-season soups, as additional salt and Cayenne may be added at table, if required.

4985. *Mullagatawny Soup.*—It is best prepared by stewing down for the stock a couple of old fowls with vegetables, estimating one fowl to each quart of soup. When these have been sufficiently boiled, strain off the liquor, and have ready prepared a young and tender fowl cut into convenient pieces in the same manner as giblets are divided; thicken the soup with butter, flour, curry powder, and the livers of the fowls previously parboiled and well beat together in a mortar; then put in the pieces of fowl, and let it simmer about an hour; season as usual.

4986. *Mock Turtle Soup.*—When you receive the calf's head, detach the scalp and separate the tongue; wash the latter in cold water, and then in warm, to draw out the blood; put these into a stew-pan with two quarts of water and a little salt; let it simmer gently, removing the scum, and peeling the tongue at the convenient opportunity; let them boil until tender; in the mean time, divide the head and take out the brains (which may be employed for a side dish); wash the head well, and lay it in warm water to soak out the blood. Crack the bones of the head and jaws, that they may lie in a smaller compass, and cleanse the bones of the nose. Have ready another stew-pan lined at the bottom with slices of fat ham or bacon; put in the head, together with the vegetables, consisting of sliced turnips and onions, one of them whole, stuck with a few corns of pepper and four cloves, the white part of two leeks, two table-spoonfuls of chopped mushrooms, a bunch of sweet herbs, the rind of half a lemon, and a little salt; moisten with some veal stock, and set it on the fire to heat gently. When the scalp and tongue in the other stew-pan are sufficiently done, take them out and divide them into convenient pieces; add the liquor in which they have been boiled to the head and vegetables, and let them simmer for two hours. Prepare the forcemeat balls in the following manner: Pound some lean veal in a mortar, and when it becomes a uniform mass, add crumb of bread, a little minced eschalot, chopped parsley, and mushroom powder, the yolks of two eggs boiled hard, Cayenne pepper, and salt; beat these with the yolks of two raw eggs and sufficient flour to form a paste of proper consistence, which roll into balls; boil them a few minutes in salt and water to harden. When the head and vegetables have stewed the prescribed time, strain off the liquor and remove all fat. Add veal stock sufficient to make in the whole three quarts of liquor; thicken with butter and flour, put in the divided scalp, tongue, and forcemeat balls, with two glasses of sherry; let it simmer for half an hour, and a little before you remove it from the fire season with salt, Cayenne pepper, and the juice of a lemon, or the latter may be added at table. Neither this nor the real turtle soup can be classed as a winter soup only. It may be regarded, however, as less acceptable in the warm seasons than in autumn and winter. (See "Real Turtle Soup.")

4987. *Giblet Soup.*—Stew in two quarts of water three sets of giblets thoroughly cleansed, with some sweet herbs, three large onions, some eschalots, allspice, pepper, and salt; let them continue on the fire until nearly done, then pick out the giblets and divide them into pieces. Let the liquor in which they have been stewed boil slowly with the vegetables about an hour longer, then strain it and remove the fat. To the strained liquor (which will be about a quart) add two quarts of beef stock, put in the giblets, and let the whole simmer until they are done; thicken with some butter and flour, and, lastly, add the seasoning, which should consist of Cayenne pepper, some juice of lemon, and, if you approve it, a gill of sherry. Some persons introduce balls of forcemeat, but this soup is sufficiently rich without them.

4988. *Soup Maigre.*—Put into a gallon stew-pan three ounces of butter; let it remain over a slow fire; while melting, slice four ounces of onion; cut in small pieces one turnip, one carrot, and a head of celery;

put them into a stew-pan, cover it close, and let them fry till they are of a light brown; this will take about twenty-five minutes. Have ready in a sauce-pan a pint of pease, with four quarts of water; when the roots in the stew-pan are quite brown, and the pease come to a boil, put the pease and water to them, set it on the fire, and when it boils, skim it and put in a crust of bread about as big as the top of a two-penny loaf, twenty-four berries of allspice, the same of black pepper, and two blades of mace; cover it close, let it simmer gently for one hour and a half, then set it from the fire for ten minutes; pour it off very gently, so as not to disturb the sediment at the bottom of the stew-pan, into a large basin; let it stand about two hours till it is clear; while this is doing, shred one large turnip, the red part of a large carrot, three ounces of onions minced, and one large head of celery cut into small bits; put the turnips and carrots on the fire in cold water; let them boil five minutes, then drain them on a sieve; next pour off the soup clear into the stew-pan, add the roots, put the soup on the fire, and let them simmer gently till the herbs are tender, about thirty or forty minutes; season it with salt and Cayenne, and it is ready. You may add a table-spoonful of mushroom catsup.

To make this, it requires nearly *five hours.* To *fry* the herbs requires *twenty-five* minutes; to *boil* all together, one hour and a half; to *settle*, at least two hours; when clear, and put on the fire again, half an hour more.

4989. *Old Pea Soup.*—Boil a pint and a half of split pease tied up in a cloth until they are quite tender; slice two carrots, three turnips, three large onions, two heads of celery, and a leek; add some pepper; let these warm, moistened with beef stock until they are thoroughly soft; rub the pease and stewed vegetables through a tamis; add to them sufficient beef stock to render the soup of the desired consistence, and let it boil gently for half an hour to incorporate. Stir it frequently, give the necessary seasoning, and serve it with fried bread cut into dice, and some powdered mint. For a family dish, the liquor in which a leg of pork has been boiled may serve instead of beef stock.

4990. *Celery Soup.*—Take six heads of celery, cut them into pieces about two inches long, wash and drain them on a hair sieve, and put them into a gallon of stock. (See "Clear Gravy Stock.") Stew the whole together for an hour, season with salt only, and serve.

4991. *Vegetable Winter Soup.*—Peel and slice six potatoes, six onions, six carrots, four turnips; fry these in half a pound of fresh butter; put them, when fried, into a soup-kettle, and pour on them four quarts of boiling water; toast a crust of bread very brown without burning it, and put it to the soup, with a head of celery cut small, white pepper, and salt; stew the whole gently for four hours; an anchovy, if added, will improve the flavour. Strain the whole through a tamis, and serve it very hot.

Subsect. 3.—*Spring Soups, White and Vegetable.*

4992. *White soups* have for their basis veal stock instead of beef; and the materials are blended into a uniform fluid, resembling cream, by means of a leason (a word corrupted by cooks from the French liaison), which means the medium of union or incorporation.

4993. *To make the Leason.*—Mix well together the yolks of four eggs with half a pint of cream and a little salt. Or the leason may be formed of almond paste, prepared in the following manner: blanch some sweet almonds, and when cold pound them in a mortar to a uniform paste. Examples for the employment of both will be now given.

4994. *Veal Stock.*—Cut up a knuckle of veal, of lean ham, or gammon, one pound; put these into a stew-pan, with a peeled carrot, turnip, onion, leek, and celery, and add one quart of water; draw these down till nearly done, removing scum and not allowing it to colour. Then add as much beef broth as will cover the whole, and add game to it if possible, as greatly improving the flavour. When these have been gently boiling for one hour, skim off the fat carefully and strain it. Be careful not to burn it, or allow any of the ingredients to become brown, or it will not answer for white soups and gravies.

4995. *Vermicelli Soup.*—Make two quarts of white stock hot; put into it half a pound of vermicelli, and *simmer* the soup for half an hour. If boiled quickly the vermicelli will burst and make the soup thick, which it ought not to be.

4996. *Macaroni Soup.*—Boil a pound of the best macaroni in a pound of good stock; when it becomes tender, take out half of it. To the remainder add some more stock, and boil it till the macaroni will pulp through a fine sieve. Add a pint of boiling cream, the macaroni that was first taken out, and half a pound of grated Parmesan cheese; make it hot again, but do not let it boil. Serve with French roll.

4997. *Chicken Soup.*—Take a couple of chickens, or a large young fowl; divide them down the back, as for broiling, and lay them in warm water and a little salt to discharge the blood; then set them to boil in three quarts of veal stock, add some green onions, a few small mushrooms, and a piece of lemon peel; when it begins to boil, carefully remove the scum. As soon as the chickens are about three parts done, take them out, remove the skin, and pick out all the white meat; score or chop the other parts, return them to the veal stock, and let them gently simmer for an hour longer, closely covered. Put the white meat into a mortar with sufficient almond paste, and crumb of bread soaked in milk and afterward squeezed in a napkin. Beat all these intimately together, moistening from time to time with a little strained broth, until it acquire the consistence of thick cream; now strain off the veal stock, and mix them together. Let them gently boil a quarter of an hour, add the appropriate seasoning, and serve up with pieces of French roll, not toasted. This is a very elegant, wholesome, and nutritious soup. *N.B.*—For the purposes described, a large marble mortar, with a wooden pestle, is an indispensable utensil in the kitchen.

4998. *Sorrel Soup.*—Take two pecks of young sorrel leaves, pick them from the stalks, wash, and drain them. Set them in a stew-pan over a slow fire, with a quarter of a pound of butter; when softened, drain them over a sieve for two minutes, and put them again into the stew-pan, with a small bit of butter, and half a pint of second stock, or consommé. (See Receipt, "Second Stock.") When reduced to half the quantity, add half a pint more, and a few table-spoonfuls of plain meat stock; boil all together and pass through a tamis. Add next a whole quart of stock, and boil it again gently for two hours before dinner. Just before it is to be served beat together six eggs, and mix them first with half a pint of cream, and then gradually with the boiling soup.

4999. *Green Pea Soup.*—Take two quarts of large green peas, not too young, three middle-sized turnips, two cabbage lettuces, and a dozen green onions. Boil these with a little pepper in a quart of first veal or beef stock (the former is preferable) until quite tender: mash or pound them to a pulp, and rub them through a *tamis*. Add two quarts of veal stock, and if you wish a richer and more nutritious soup, a pint of veal consommé. Then take a quart of young green pease, which heat gently over a slow fire until they are tender; add these to the soup, with some flour and butter to give the proper consistence, and boil them for half an hour. A few leaves of green mint may be introduced, if approved; and if it be required to have the soup very green, boil a bunch of parsley, and rub it through a hair sieve, which will give the desired colour: if any slight acidity should prevail from the vegetables, a lump of sugar will remove it. Season to the palate, and serve it as usual with fried bread.

5000. *Asparagus Soup.*—This is made with the points of asparagus in the same manner as the green pea soup is with pease; or by adding the asparagus heads to common pea soup.

Subsect. 4.—*Game Soups.*

5001. *Game Soups*, in houses well supplied with game, may be made at a very moderate expense. Take the meat from the breasts of birds, hares, or rabbits that may have been left from the preceding day's dinner, and pound it. Beat the bones to pieces, and boil them in broth for an hour. Boil and mash six turnips, strain them with the pounded meat through a tamis, passing the broth at the same time, by which means the whole will be got through. Put these ingredients into the soup-kettle, and set it near a moderate fire, never allowing it to boil. When it is to be served, beat the yolks of six eggs, and mix with them half a pint of cream; strain them through a sieve into the soup, which should be nearly boiling; stir the eggs and cream well into it to prevent them becoming curdled.

5002. *Hare Soup.*—Empty a hare; reserve the liver and parboil it. Cut the hare into junks, or thick pieces; trim the bottom of a stew-pan with slices of fat ham or fat bacon. Have ready cut some carrots, turnips, and onions, one of which should be whole and stuck with six cloves, a blade of mace, and a few corns of pepper, a bunch of parsley, and some sweet herbs, two table-spoonfuls of chopped mushrooms, two eschalots minced, and a piece of lemon peel, with a little salt. Fill the trimmed stew-pan with the pieces of hare and vegetables, and moiston with a pint of beef stock and a gill of port wine. Let these gently simmer together, closely covered, on a very slow fire for two hours. Then remove the stew-pan from the fire, and take out the best pieces of the hare, as the thighs and back; pick the meat clean from the bones, which latter return into the stew-pan. Pound the meat you have picked off with the parboiled liver in a mortar, and when it becomes a smooth and uniform mass, add a large lump of flour and butter intimately mixed, and rub them through a tamis. Replace the stew-pan on the fire, with sufficient beef stock to afford three quarts of soup, and let them gently simmer an hour more; then strain it off and remove any fat. Mix gradually the pounded meat of the hare with the strained liquor, and set it on the fire for twenty minutes to thicken and combine.

5003. *Partridge Soup.*—Skin and cut to pieces two large partridges, with three or four slices of ham, a little celery, and three large onions. Fry them in butter till brown, but mind they do not burn; then put them into a stew-pan with three quarts of boiling water, a few peppercorns, and a little salt. After stewing gently for two hours, strain it through a sieve; put it again into the stew-pan with some stewed celery and fried bread When near boiling, pour it into a tureen, and serve it quite hot.

Subsect. 5.—*Fish Soups.*

5004. *Stock for Fish Soup.*—Take a pound of skate, four or five flounders, and two pounds of eels; clean them well and cut them into pieces; cover them with water and season them with pepper, mace, salt, an onion stuck with cloves, a head of celery, two parsley roots sliced, and a bunch of sweet herbs; cover them close, stew for an hour and a half, and then strain it off for use. If for brown fish, first fry the fish brown in butter, and then do as above. It will not keep more than two or three days.

5005. *Eel Soup.*—Take a couple of middling-sized onions, cut them in half, and cross the knife over them two or three times; put two ounces of butter into a stew-pan, put in the onions, and stir them about till they are lightly browned; cut into pieces three pounds of unskinned eels, put them into your stew-pan, and shake them over the fire for five minutes; then add three quarts of boiling water, and when they come to a boil take the scum off; then put in a quarter of an ounce of the green leaves (not dried) of winter savoury, the same of lemon thyme, and twice the quantity of parsley, two drachms of allspice, the same of black pepper; cover it close, then let it boil gently for two hours, strain it off, and skim it clean. To thicken it, put three ounces of butter into a stew-pan; when it is melted, stir in as much flour as will make it of a thick paste, and add the liquor by degrees; let it simmer for ten minutes, and pass it through a sieve; put your soup on in a clean stew-pan, and have ready some little square pieces of fish fried of a nice light brown, either eels, soles, plaice, or skate will do. The fried fish should be added about ten minutes before the soup is served; forcemeat balls are sometimes added.

5006. *Lobster Soup.*—Boil three fine young hen lobsters ; when cold, split the tails, take out the meat, crack the claws, and cut the meat into small pieces ; take out the coral and soft parts of the body ; bruise part of the coral in a mortar with part of the meat from the chines, and with this make forcemeat balls, seasoned with mace or nutmeg, anchovy, grated lemon peel, and Cayenne ; pound these with the yolk of an egg. Have three quarts of veal stock, bruise the small legs and chine, and put them into the stock to boil for twenty minutes ; then strain it, and to thicken it, take the fresh coral and bruise it, and put it into a mortar with a little butter and flour ; rub it through a sieve, and put it to the soup with the meat of the lobsters and the remaining coral. Let it simmer very gently for ten minutes ; do not let it boil, or its fine red colour will immediately fade. Pour it into a tureen ; add the juice of a lemon and a little anchovy.

5007. *Cray-fish Soup.*—Put six whitings, and one eel, and a thornback into cold water, and set them on the fire ; as the scum rises in boiling it must be carefully removed. An onion, carrot, and some parsley, together with a few peppercorns, must be added. Then remove the shells of fifty cray-fish, and add them to the soup, together with the small claws and shells finely pounded. Boil the whole an hour ; then strain off the soup, and put in some pounded crusts of bread, and then sprinkle over the spawn of a lobster.

5008. *Prawn soup* is made in the same way.

5009. *Common Fish Soups.*—Excellent fish soups may be made of the scull of cod, skate, or flounders, boiled in no more water than will cover them, and the liquor thickened with oatmeal.

5010. *Turtle Soup.*—The head of the turtle should be cut off the evening previous to the day on which the soup is to be made, and the turtle hung up by the fins, with the neck downward. In the morning cut off the *fore* fins, and the callipee all round ; remove the entrails and carefully detach the gall ; then cut off the *hind* fins, and separate all the meat from the bones, both callipee and callipash, and cut it into pieces. Scald these all together, taking care the scales do not set. When cleaned, chop the fins into pieces four inches long, and put them, with the other pieces and bones, into a pot, with sufficient water to cover them ; throw in a bunch of sweet herbs and some whole onions, and when the liquor boils, take off all scum and froth. When these are nearly done, take them out and detach the bones from the fins ; strain the liquor, and reduce it by boiling to about one third of its original quantity. Divide the meat into pieces of a convenient size for the mouth ; put them into a pot, with some parsley, thyme, savoury, knotted marjoram, basil, and green onions, chopped fine together, with some pounded spices, consisting of clove, black pepper, mace, allspice, and salt. Pour over them the reduced liquor, and some good veal stock ; let it boil very gently till three parts done, and clear it free from the herbs. Let the liquor be strained through a tamis, and thickened with flour and butter (passed), and add a bottle of Madeira wine. Set it on the fire to boil, add the meat, and, lastly, put in the juice of five or six lemons, and a seasoning of Cayenne pepper and salt. When served, put in forcemeat balls previously prepared, together with some of the real green fat, divided in moderate portions. In countries where turtle is abundant and cheap, the broth in which it is prepared is made of the turtle only, whereby the flavour is much improved.

Sect. V.—GRAVIES.

5011. *Beef Gravy.*—In plain family cooking, stock, or consommé, is seldom in daily request, and, consequently, small quantities of gravy are made as occasion demands. Gravy, as well as soup, is an extract of the soluble and nutritious juices of meat, united in certain proportions to those of vegetables, which are, in fact, the flavouring ingredients.

Let the proportion of beef to water be a pound to a pint ; pepper and flour the meat, put it into a well-tinned pan, in which a small lump of butter has been previously melted. Set the stew-pan, *uncovered,* over a clear fire, until the meat becomes brown ; remove it to a soup-plate, and score it with a knife in various places, to allow the gravy to flow out. In the mean time, put into the same sauce-pan, and by the same process draw out the juices of one carrot, one onion, and some celery, all cut small. When these are heated, or, as the cook terms it, *sweated,* add to them the meat and its gravy, and a pint of boiling water ; boil all together, and scum the surface continually, and when the scum ceases to rise, cover the pot, and let it simmer gently for an hour or more. Strain it off, and if not immediately wanted, let it cool, in order to remove more entirely the fat than can otherwise be done, as well as to pour it, after it has settled, clear off from the sediment.

5012. *Veal Gravy.*—Veal gravy may be obtained by the same plan as the last, but it requires a greater proportion of meat to water than beef gravy, and instead of butter, the sauce-pan should be lined with slices of fat bacon. The cover of the stew-pan should be put on while both meat and vegetables are sweating, as one object is to keep the gravy from becoming brown. Of vegetables use only parsley, green onions, and mushroom parings.

5013. *Browning.*—This is used to give a fine brown to gravies ; it is prepared by putting a quarter of a pound of good moist sugar into a frying-pan, with three table-spoonfuls of water ; this is kept over the fire and stirred all the time, until it becomes of a deep brown colour ; another pint of water is then added ; it is to be skimmed well while boiling, and after it is done it must be bottled and well corked.

5014. *Gravy for Roast Beef.*—Melt a little salt in a quarter of a pint of boiling water, about an hour before a joint of roast beef is to be served, place an earthen-ware dish under it, and drop some of the salt and water on the brown parts of the roast, catching it in the dish beneath. When enough is thus obtained, set to cool, in order to remove the fat from it ; this being done, warm it in a sauce-pan, and pour it over the beef when it is served.

5015. *Gravy for Roast Mutton.*—Make a gravy of mutton, without vegetables, and remember to send some of this in a tureen whenever there is a saddle or haunch of mutton to be served. Venison, also, should have mutton gravy, unless there are sufficient venison trimmings to make it. Put no seasoning except a little salt to either mutton or venison gravy. Browning may be added.

5016. *Gravy for Steaks and Chops.*—Pour away the fat in which steaks or chops have been fried ; put in a small lump of butter, and, while it is melting, dredge it well and continually with flour, until it becomes a thick mass; then add a little boiling water and any flavouring ingredient, such as mushroom or walnut catsup, whichever the meat requires, with which it is to be served.

5017. *Savoury Jelly for Meat Pies.*—This is a composition of animal and vegetable substances, reduced by slow boiling to a jelly. Stick two large onions with a few cloves, peel three eschalots, slice two carrots, a bundle of parsley and sweet herbs; put these into the stew-pan with four pounds of chuck beef, two calf's feet, remnants of poultry and game, with a knuckle of veal and some ham. Let these ingredients heat together for an hour over a slow fire; moisten with some beef or veal stock, and let it stew gently for four hours; remove all the fat and strain it; then clarify it with the whites of eggs; and when cold it will be a jelly.

5018. *Gravy for Hashed Meat.*—Make a gravy of the bones of the meat to be hashed; break the bones, and, if for mutton, put in an onion sliced, some celery cut small, and a carrot and turnip; pour boiling water over them, and simmer gently for two or three hours; strain all through a sieve. If to be served thickened, stew some sliced potatoes with the vegetables, and pulp all together through the sieve, or tamis. Season with pepper and salt; flavour with mushroom catsup for veal or mutton; with walnut catsup for beef.

5019. *Gravy for Poultry.*—Add the liver, necks, and feet of poultry, either to the brown beef stock (see "Beef Gravy"), or to the white veal stock (see "White Veal Stock"), according as the poultry is to be dressed, whether fricasseed or ragouted.

5020. *Gravy for Game.*—Add to the beef gravy (see "Beef Stock") the trimmings of game rabbits, one table-spoonful of mushroom catsup, and the juice of half a lemon.

5021. *Turtle Gravy, for Hashed Calf's Head.*—Thicken with butter and flour a pint of beef gravy; and a wine-glass of Madeira, the juice and peel of half a lemon, a few leaves of basil, an eschalot sliced, a few grains of Cayenne or curry powder, two tea-spoonfuls of anchovy essence. Simmer these together for five minutes, and strain through a tamis. Add or omit, as may be convenient, a dozen of turtle forcemeat balls.

Sect. VI.—sauces.

5022. *White Roux, or Thickening for Sauces.*—Melt some butter in a stew-pan over a slow fire, and dredge in sufficient flour to form a thin paste; stir this for ten minutes to incorporate. By submitting the same materials to a brisker fire in the beginning, and then continuing the process over a more gentle heat, it will assume a brown colour, and is then termed *brown roux.* These are the usual thickenings for all gravies and sauces, and when thus prepared will keep good for a considerable time.

5023. *Liaisons, or Leasons.*—These are thickenings for white sauces, formed of egg and cream; the yolk of egg beaten well is mixed with cream, and both are gradually mixed with the hot broth or stock which is to be thickened. Care must be taken not to *boil* this mixture, which would cause the eggs to curdle. When cream is not at hand, the yolk of an egg thus combined with the gravy serves as a substitute for thickening.

5024. *Bread Sauce for roasted Poultry and Game.*—Put a tea-cupful of bread crumbs into a sauce-pan, and pour over them half a pint of milk; add an onion and a dozen black peppercorns. Let it boil, stirring it well together; then simmer it till it becomes stiff. Take out the onion and pepper, and, with butter and cream, reduce the bread to a proper consistence. Serve in a tureen.

5025. *Gooseberry Sauce.*—The accompaniment to a boiled leg of house lamb, or to mackerel. After cutting off the tops and tails with scissors, half a pint of gooseberries must be scalded, drained on a sieve, and then put into a pint of melted butter. (See "Melted Butter.") For mackerel, some add finely-chopped fennel to the gooseberries; other cooks flavour the sauce with ginger and lemon peel; and occasionally the gooseberries are merely scalded and sent up whole, without any mixture of butter or other things.

5026. *Green Mint Sauce.*—This is principally eaten with roast lamb, either hot or cold, in the early part of the season. It consists of green mint finely chopped with a little parsley, a tea-spoonful of moist sugar, and a wine-glassful of vinegar.

5027. *Young Onion Sauce.*—Peel a pint of button onions, and put them in water till you want to boil them: put them into a stew-pan with a quart of cold water; let them boil till tender; they will take, according to their age, from half an hour to an hour. You may put them into half a pint of melted butter, to which two spoonfuls of mushroom catsup has been added.

5028. *White Onion Sauce for boiled Rabbits, or roasted Shoulder of Mutton.*—For this sauce the Spanish are the mildest. Peel and cut them in half; lay them in cold water for ten or fifteen minutes; then boil them for another quarter of an hour; and, to render them very mild, pour off this water, and with fresh boiling water boil them up once more; drain them on a sieve, put them on a chopping board, and cut them very fine. In a fresh sauce-pan put them again on the fire, adding a small lump of butter, half a pint of cream or milk; stir it till it boils, and if too thick, add more milk or cream; rub it through a tamis, or sieve; put it again into the sauce-pan to make it warm again; and pour into the tureen when the dish is served which it is to accompany.

5029. *Brown Onion Sauce.*—Peel and slice some onions (some put in an equal quantity of cucumber or celery) into a quart stew-pan, with an ounce of butter; set it on a slow fire, and turn the onion about till it is lightly browned; now gradually stir in half an ounce of flour; add a little broth, pepper, and salt; boil up for a few minutes, and add a table-spoonful of claret or port wine, and some of mushroom catsup (you may sharpen it with lemon juice or vinegar), and rub it through a hair sieve.

5030. *Curry Powder will convert this into excellent Curry Sauce.—N.B.* If this sauce is for steaks, shred an ounce of onions, fry them brown, and put to the sauce you have rubbed through the tamis; or some small silver button onions, peeled and boiled tender, and put in whole when your sauce is done, will be an acceptable addition. The flavour of this sauce may be varied by adding Tarragon or Burnet vinegar.

5031 *Caper Sauce.*—Chop a table-spoonful of capers very small, and boil them up in melted butter. See receipt for "Melted Butter."

5032. *Parsley and Butter.*—Put a lump of butter into a sauce-pan, and as it begins to dissolve, shake in flour till it forms a thick paste; bring this to a proper thickness with water; chop the parsley very small after having soaked it in boiling salt and water; put it to the butter and give it a boil up, stirring it all the time. Serve it in a tureen.

5033. *Mushroom Sauce.*—This is best made by pounding a pint of the small or button mushrooms with about an ounce of butter and a table-spoonful of fine flour; work this well over a gentle heat, moistening with veal gravy and a little cream: it requires to be well seasoned. Some persons add a dessert-spoonful of cavice; others the same quantity of lemon juice.

5034. *Tomato Sauce.*—This is usually eaten with fried lamb chops: it is also well adapted for game. When the tomatoes are ripe, stew half a dozen large ones in a pint of beef gravy, with two tea-spoonfuls of minced eschalots; when they become tender mash them, and pass the pulp through a tamis; set this on a moderate fire to reduce with a glass of sherry, or other white wine. Towards the end of the process, when it has acquired a proper consistence, add sufficient Cayenne pepper, salt, and a little lemon juice. This sauce may be preserved in bottles, but it is much superior when fresh made.

5035. *Apple Sauce.*—This is made by boiling apples after they have been pared and the core extracted, with a little allspice tied up in a muslin rag; when sufficiently tender, mash them, add a very small piece of butter, and sweeten with moist sugar.

5036. *Wine Sauce for Venison.*—To a quarter of a pint of claret, or of port wine, add the same quantity of mutton gravy (unseasoned), and a table-spoonful of currant jelly: boil them, and serve them in a sauce-tureen.

5037. *Sharp Sauce for Venison.*—Put into a clean, well tinned sauce-pan, half a pint of good white wine vinegar, and a quarter of a pound of loaf-sugar pounded. Let these simmer gently by the fire; skim the surface of the liquid carefully, and serve hot in a tureen.

5038. *Sweet Sauce for Venison, Hare, or Roasted Mutton.*—Melt currant jelly in a sauce-pan, adding to it two table-spoonfuls of hot water.

5039. *Melted Butter.*—Melted butter, said by foreigners to be the only English sauce; and it would not be so difficult an art to make it well, if it were not often done in a hurried and careless manner. Sometimes the butter is oiled, and floats on the surface; sometimes there is too much, and sometimes too little flour; and generally too much boiled. Let the cook keep a pint sauce-pan for this purpose only, and remember that about two ounces of butter will make a sufficient quantity for one tureen. Put the butter into the stew-pan, with a large tea-spoonful of flour and two table-spoonfuls of milk; when melted and mixed together, add six table-spoonfuls of water; shake the sauce-pan constantly while holding it over the fire, taking care that the contents go one way. When it begins to simmer, it may stand quietly and boil up; pour it into a tureen as soon as it boils. If the butter oils, put a spoonful of cold water to it, and stir it well; if that does not succeed, try the pouring it backward and forward from the sauce-pan into the basin. Melted butter made to be mixed with essences and catsups should be of the thickness of a light batter.

5040. *Clarified Butter.*—Put butter into a nice, clean stew-pan over a clear, slow fire; watch it, and, as it melts, skim away the butter-milk it casts up; let it stand for a minute, that impurities may sink to the bottom; pour the clear butter through a sieve into a clean basin, leaving the sediment in the stew-pan.

5041. *Burned Butter.*—Put a lump of butter into a frying-pan; when melted, and it becomes brown, add to it a table-spoonful and a half of vinegar, a little pepper, and salt.

5042. *Butter, oiled (for frying Fish, instead of Olive Oil).*—Melt two ounces of butter in a sauce-pan or cup; put into hot water: it can scarcely be done too gradually. From the sediment at the bottom it must be poured away.

Fish Sauces.

5043. *Oyster Sauce.*—Preserve the liquor of the oysters, and the beards when taken off; boil up the liquor and beards together; strain it and put in the oysters; warm them in it for a few minutes; then take them out and drain them; strain off the liquor clear. Put into a stew-pan a small bit of butter with a spoonful of flour, and fry them together; dilute this with the oyster liquor and two table-spoonfuls of cream; let it boil gently, then add the oysters. When boiled sufficiently, season it with salt and with a spoonful of essence of anchovy. Serve in a tureen.

5044. *Lobster Sauce.*—Mash or pound the fresh eggs of the hen lobster, which squeeze through a piece of muslin and reserve; divide the flesh of a boiled lobster into convenient bits, and dust them with a little flour to prevent them from adhering together; put them into a sauce-pan with sufficient butter and cream, or milk, constantly stirring over a gentle fire until dissolved; let it simmer a minute or two, then add the strained eggs, or spawn; and when it assumes a brilliant red colour, instantly remove it from the fire, as the continuance of a boiling heat would destroy its fine redness. Those who prefer the flavour of anchovy, cavice, or lemon juice, may make the addition at table.

5045. *Shrimp Sauce.*—When the shrimps are picked at home, reserve the bodies and shells, and stew them in a little water; strain this liquor through muslin, and employ it with sufficient butter, flour, and the picked shrimps. Some persons pound the picked shrimps into a paste, which may be afterward mixed with the butter, flour, and the water in which the bodies have been stewed. In this way the sauce becomes strongly impregnated with the flavour of the shrimps.

5046. *Anchovy Sauce.*—Take a couple of anchovies, pick them clean from the bones, and pound them to a paste with some flour. When sufficiently smooth, add two ounces and a half of butter, and incorporate it with the anchovy paste; put this mass into a sauce-pan with nearly a pint of milk or cream, and set it over a gentle fire to dissolve, frequently stirring it; when it has simmered a minute or two, it will be of the requisite consistence. Made with the essence of anchovy, two table-spoonfuls will be necessary to flavour half a pint of good melted butter. It should be served hot, and have the juice of half a lemon squeezed into it.

5047. *Fennel and Butter for Mackerel.*—After the fennel is washed, boil it in half a pint of salt and water for six or seven minutes; drain it and mince it very small. Mix it well with melted butter, and serve it in a sauce tureen. Fennel and parsley sauce is sometimes preferred to fennel sauce alone. A sprig of mint and an onion chopped very small are also sometimes added.

5048. *Mackerel Roe Sauce.*—Boil the soft roes of mackerel, and bruise them with a spoon; then mix them with the yolk of an egg well beaten. Add to them salt and pepper, and some fennel and parsley boiled and chopped small. To these must be added half a pint of thin melted butter. Some add mushroom catsup, or walnut pickle and soy.

5049. *Egg Sauce for salt Fish.*—Boil three eggs for twelve minutes, and harden them by putting them immediately into cold water; this will also prevent the surface from becoming black. Chop all the yolks, but only half the whites, into small square dice, and, after putting them into the sauce tureen, pour upon them half a pint of melted butter, not too thick. Stir these well together.

5050. *Liver Sauce for Fish.*—Boil the liver of the fish and pound it in a mortar with a little flour; stir it into broth, or some of the liquor the fish was boiled in, or in melted butter, parsley, and a few grains of anchovy essence, soy, or catsup. Give it a boil, and run it through a sieve. You may add lemon juice or lemon cut in dice.

5051. *A very fine Sauce for Fish.*—Put into a well-tinned sauce-pan a pint of port wine, a glass of mountain, half a pint of fine walnut catsup, twelve anchovies and the liquor belonging to them, three or four table-spoonfuls of walnut pickle, and the rind of half a lemon. A few eschalots and Cayenne, to taste, may be added. Also, three ounces of scraped horseradish, two or three blades of mace, two tea-spoonfuls of made mustard. Boil all gently together till the rawness of the taste is lost. Put it into a jug to cool, and thence pour it into pint bottles and cork them close.

5052. *Cullis for Fish.*—Broil a jack or pike, then take off the skin, and separate the flesh from the bones. Boil six eggs for twelve minutes, and take out the yolks; blanch and beat to paste a few almonds. Add the eggs, and mix these all together with butter; put in the fish, and pound the whole mass together. Set a stew-pan on the fire with a piece of butter to brown, and when boiling put half a dozen onions sliced, two parsnips, and three carrots, to brown also; pour to them afterward a little broth to moisten them. When these have boiled for a few minutes, strain them into another sauce-pan, put in a whole leek, some parsley, sweet basil, half a dozen cloves, some mushrooms, truffles, and bread crumbs, and let them stew together for a quarter of an hour, when the fish, eggs, and almonds from the mortar must be added, and the whole stewed together some time longer, but not boiled. When sufficiently done, strain it through a hair sieve.

Sect. VII.—Forcemeats and Flavouring Ingredients.

Subsect. 1.—*Forcemeats.*

5053. *To compound forcemeats*, and to use discriminately flavouring ingredients or condiments, is the next branch in cooking to which attention must be given. Forcemeats should have the various ingredients of which they are composed equally incorporated, so that the whole mass may be uniform in quality and flavour. Flavouring herbs or condiments employed in forcemeats should be carefully added, all predominance in any one over the rest being avoided. As in these flavours it is impossible to state precisely how much of each should be used, the cook must accustom herself to taste and to judge for herself of the due proportion of each; experience will give her delicacy and accuracy of taste. Accuracy, in regard to flavour, is an important attainment in a cook; perhaps none can be eminent who do not strive to acquire it.

5054. *Forcemeat for Veal or Turkey, roasted.*—A forcemeat for roasted veal or turkey should be made of equal quantities of finely-minced suet and grated bread, somewhat less than a quarter of a pound of each. About two ounces of each will be enough for a turkey poult. Some add, finely chopped, some parsley, sweet marjoram, lemon thyme, some grated lemon peel, a very small slice of onion (minced extremely fine), a little pepper and salt. When these are mixed equally together, the whole must be united by adding an egg to it, or, if insufficient, two eggs, previously well beaten, must be employed to bring it into one consistent mass.

Forcemeat for boiled Turkey.—Chop half a pound of lean veal, two anchovies, the same quantity of beef suet, a few oysters (bearded), some bread crumbs, incorporated together with yolks of eggs. To these some cooks add a flavour of herbs. Stuff the crop of the turkey, and prepare it for boiling.

5055. *Stuffing for Goose or Ducks.*—Chop onions very small, with half the quantity of sage leaves. To these add a tea-cupful of grated bread, a small lump of butter, some pepper and salt, and incorporate the whole with the yolk and white of an egg beaten up.

Another Way.—Boil the onions and sage, and then chop them very small, and put into the goose or ducks without any other addition except that of pepper and salt.

5056. *Stuffing for Hare or roasted Rabbit.*—If the liver be perfectly fresh, parboil it, and mince it very fine; add to it a small tea-cupful of beef suet chopped fine, the same quantity of grated bread, a bunch of parsley, also finely chopped, some marjoram, lemon thyme, and grated lemon peel, together with a shred or two of eschalot, and a little pepper and salt. Mix these together with an egg into a tolerably stiff mass; put them into the hare, and sew up the skin.

5057. *Stuffing for roasted pigeons*, the same as for veal. For *stewed pigeons*, boil and bruise the livers, and add to them a little butter, a few bread crumbs, some pepper, salt, pounded cloves, chopped parsley, and sweet herbs; mix these ingredients together, and put a portion into each pigeon.

5058. *Forcemeat for Pies.*—A pound of lean veal trimmed of all the sinews and skins, and chopped with half a pound of fat bacon, some powdered herbs, a little salt, two eggs, and a little mushroom catsup; these, mixed together, may be used rolled up with best olives, or made into balls, and added to pies or some made dishes.

5059. *A Forcemeat of Rabbit.*—Take a pound or more of the meat of wild rabbits; add to it two pounds of fat bacon, chop both together, and afterward pound them with a flavouring of herbs, a little salt, two yolks and one white of an egg.

Subsect. 2.—*Flavouring Ingredients.*

We may remind the reader that the several spices and mustard have been described in Book VII., Chap. X.; and salt is treated of in Book X., Chap. III., Sect. III.

5060. *To prepare Mustard for use.*—In this country mustard is simply made with milk, water, vinegar, or wine. The flour of mustard should be kept dry in a bottle properly corked.

First Method.—When made with water in the usual way, it has for some little time a bitter taste. To avoid this, rub in a mortar one table-spoonful of the flour of mustard with two of milk or cream, half a tea-spoonful of salt, and the same of lump sugar powdered.

Second Method.—Made with vinegar, they should be rubbed together smooth for upward of seven or eight minutes, and when done should be of the consistency of thick cream. Put it into a stone jar; and, closely stopped, it will keep good for a fortnight. That which is put into the table mustard-pot should not be more in quantity than what will be consumed in one or two days.; the air soon causes it to turn sour if it be exposed.

Third Method, according to Dr. Kitchener.—Boil three ounces of salt in a quart of boiling water or vinegar, and pour it hot on two ounces of scraped horseradish. Closely cover the jar, and let it stand twenty-four hours. Strain and mix it by degrees with the best Durham flour of mustard; beat well together till quite smooth and of the thickness of cream. Put it into a wide-mouthed bottle and stop it close.

5061. *The French flavour their mustard* with Champagne, Madeira, or other wines; or with vinegar flavoured with capers, anchovies, tarragon, elder, basil, burnet, garlic, eschalot, celery, adding Cayenne or various spices, or sweet savoury, or fine herbs, truffles, catsup, &c.; in short, considering mustard only as a vehicle for flavours. Some of these are to be had in the London shops, as Moutarde de Maille, de Bordui, &c.

Spices, such as nutmeg, mace, allspice, should be powdered and kept dry in bottles. When powdered, these ingredients go much farther, and more rapidly give out their flavour, besides being more ready at the moment they are wanted.

Subsect. 3.—*Sweet and Savoury Herbs, dried.*

5062. *As the various herbs used as condiments cannot be had at all times of the year in a fresh state*, means have been found for preserving their flavours. Drying and reducing them to powder is one of the methods practised. The common method of drying is to put them into paper bags, and lay them on a shelf in the kitchen, exposed to all the fumes, steam, smoke, &c., by which they soon lose their flavour; but the following method is greatly preferable. The substances to be preserved should be gathered on a fine day, at the time when they are in the highest perfection. Having cleaned them well by separating the leaves from the stalks, and having separated the dirt by rubbing them with the hands over a hair sieve, which will suffer the dust to go through by shaking, they are to be put into a common oven, or a Dutch oven, before the fire, and dried quickly, but not so as to burn. This method is preferable to drying them more slowly by the heat of the sun. When quite dried, they are pounded in a mortar, passed through a sieve, and the powder put into bottles well stopped; in this way parsley, winter savoury, sweet marjoram, lemon thyme, sweet basil, bay leaves, celery seed, lemon peel, horseradish, mint, sage, tarragon, burnet, mushrooms, and others of this class, will retain their fragrance and flavour for several months.

5063. *Seasons for drying Sweet Herbs.*—*Basil* is in the best state for drying from the middle of August and three weeks after. *Knotted marjoram*, from the beginning of July and during the same. *Winter savoury*, the latter end of July and throughout August. *Summer savoury*, at the same time. *Thyme, lemon thyme, orange thyme*, during June and July. *Mint*, latter end of June. *Sage*, August and September. *Tarragon*, June, July, and August. *Burnet*, June, July, and August. *Parsley*, May, June, and July. *Chervel*, the same. *Fennel*, the same. *Elder flowers*, the same. *Orange flowers*, May, June, and July.

5064. *It is found convenient to keep ready prepared mixtures of these powders*, for flavouring certain soups and ragout, of which the following may serve as a specimen: Dried parsley, winter savoury, sweet marjoram, lemon thyme, of each two ounces; lemon peel cut very thin and dried, one ounce; sweet basil, one ounce; celery seed and bay leaves, of each one drachm; or part only of these may be employed, according to taste. Another mixture, recommended for pea soup, consists of dried mint and sage, celery seed, and pepper.

5065. *The following are kept ready prepared in the London shops:* Dried mushrooms, dried truffles and morels, artichoke bottoms, bottled and green truffles.

Infusions of these may likewise be made in vinegar or white wine, which may be employed in relishing sauces; although these are inferior to the fresh gathered herbs.

5066. *Curry powder* is much used for flavouring and increasing the relish of such dishes as chicken, rabbits, veal, sweetbreads, lobster, turbot, soles, oysters, &c. It made after the following receipt, it will be found scarcely to differ from what is brought from the East:

2 oz. of coriander seed; 1 oz. of cummin seed; ½ oz. of caraway seed; ½ oz. of ginger (in powder); 2 oz. of turmeric; ½ oz. of black pepper (pounded); ¼ oz. of Cayenne (of the very best quality, or more will be necessary).

These ingredients are to be dried in an oven, pounded and sifted separately, then mixed together in a mortar, and put into a dry bottle and corked. *N. B.*—A table-spoonful will be sufficient for a large dish of curry.

5067. *A Ragout Powder:*

1 oz. of salt; ½ oz. of mustard; ¼ oz. of allspice; ½ oz. of black pepper (ground); ½ oz. of grated lemon peel; ½ oz. of ginger; ½ oz. of nutmeg; 2 drachms of Cayenne.

Dry these ingredients in an oven, pound, sift, mingle them well together, and bottle them.

5068. *Mushroom Powder.*—Wash half a peck of large mushrooms while quite fresh, and free them from grit and dirt with flannel; scrape out the black part, and do not use any that are worm-eaten; put them into a large stew-pan over the fire without water, with two large onions, some cloves, a quarter of an ounce of mace, and two spoonfuls of white pepper, all in powder; simmer and shake them till all the liquor be dried up, but be careful they do not burn. Lay them on tins or sieves in a slow oven, till they are dry enough to beat to powder; when powdered, put it into small bottles, which must be closely corked, and kept in a dry place.

5069. *Anchovy Powder.*—Pound the fish and rub them through a sieve, make them into a paste with dried flour, and roll it into thin cakes, and dry them before a slow fire (or oven). Pound them very fine, and put them into bottles. Cork them well, and the powder will keep good for many years. *N.B.—This sprinkled on bread and butter is an agreeable relish.*

5070. *Oyster Powder.*—Open the oysters carefully, so as not to cut them except in dividing the gristle which attaches the shells. Put them into a mortar, and when you have got as many as you can conveniently pound at once, add about two drachms of salt to about a dozen oysters; pound them and rub them through the back of a hair sieve, and put them into a mortar again, with as much flour (but previously thoroughly dried) as will roll them into a paste; roll this paste out several times, and, lastly, flour it, and roll it out the thickness of a half crown, and cut it into pieces about an inch square; lay them in a Dutch oven, where they will dry so gently as not to get burned; turn them every half hour, and when they begin to dry, crumble them. They will take about four hours to dry. Pound them, sift them, and put them into dry bottles; cork and seal them over. *N.B.*—Three dozen of natives required 7½ ounces of flour to make them into a paste, which then weighed 11 ounces; when dried, 6½ ounces. To make half a pint of sauce, put one ounce of butter into a stew-pan with three drachms of oyster powder and six table-spoonfuls of milk; set it on a slow fire, stir it till it boils, and season it with salt. This extract is valuable in inland countries, and equally good, when made into sauce, with fish, fowls, or rump steak; sprinkled on bread and butter, it makes a good sandwich. It is an excellent store sauce for the army and navy.

Subsect. 3.—*Store Sauces, Essences, Vinegars, and Catsups.*

5071. Under this head is an almost endless variety of flavouring ingredients, many of which, in the present state of English cookery, are almost indispensable.

Anchovy essence is one of the most esteemed of the essences. For those who prefer to have it home-made, it will be necessary to remark that success in making it depends greatly on having anchovies which have been long enough pickled, so as to dissolve easily without giving a rusty flavour to it. In choosing the fish, take care that you do not purchase sprats instead of anchovies, which are often sold for them; also, avoid having those in which red paint has been put into the pickle in order to improve the colour of the fish. Having observed these precautions, take a pound of the best anchovies you can get, and put them into two quarts of water, with two bay leaves, some whole pepper, a little scraped horseradish, thyme, two blades of mace, six eschalots chopped small, a wine-glass of port wine, and the rind of a lemon; boil all together for twenty minutes, rub them through a tamis, and pour the liquor into pint bottles; these must be corked down, and kept in a cool, yet dry place.

5072. *Soy.*—This sauce, much used for fish, comes from Japan, and is called there soja. It is made from the seeds of a plant called *Dolichos soja.* Some is also brought from China, but the Japanese is the best. It is supposed to be extensively counterfeited in this country. When genuine, it is of an agreeable flavour, neither too salt nor too sweet, of a thick consistence, and clear brown colour. When shaken in a glass, it should leave a coat on the surface of a bright yellowish-brown colour.

A somewhat similar sauce may be prepared in the following manner: Boil a gallon of the seeds of the *Dolichos soja* till they are soft; and even pease or kidney-beans may be used as a substitute; add an equal quantity of bruised wheat; put this mixture into a warm place for twenty-four hours, and add a gallon of common salt and two gallons of water. Shake the whole together, and put it into a stone jar, where it should remain closed up for two or three months, during which time it should frequently be shaken. After this time, the liquor should be pressed out through a sieve, which will constitute the soy. An inferior kind may be procured by putting salt water upon what remains, and treating it in the same manner.

5073. *Essence of Ham.*—Cut of lean ham three or four pounds into pieces about an inch in thickness; lay them in a stew-pan with slices of carrot, parsnips, and three or four onions. Let them stew till they stick to the pan, but do not burn. By degrees, pour in some good veal gravy, a few fresh mushrooms (or mushroom powder), truffles, morels, cloves, parsley, leek, basil, and a crust of bread; cover it close, and simmer it till it gets thick, then strain it off for use. *N.B.*—This essence is sold in the shops for three shillings a pound; and as a small quantity will give a strong flavour, it is by no means an expensive essence.

5074. *Soup Herb Spirit.*—Of lemon thyme, winter savoury, sweet marjoram, sweet basil, half an ounce each; lemon peel grated, two drachms; eschalots, the same; celery seed, a drachm avoirdupois weight. Infuse these in a pint of brandy or proof spirit for ten days. Neither wine nor vinegar will extract the flavour of the ingredients so well as the spirit.

5075. *Spirit of Savoury Spice.*—Black pepper, an ounce; allspice, half an ounce (*finely powdered*); nutmeg grated, a quarter of an ounce avoirdupois weight. Infuse these in a pint of brandy or proof spirit for ten days.

5076. *Soup herb spirit and spirit of savoury spice,* mixed in the proportion of half a pint of the herb spirit to a quarter of a pint of the savoury spice spirit, form a valuable auxiliary in the kitchen in heightening the flavour and giving an immediate finish to soups, sauces, ragouts, &c. They will keep for twenty years.

5077. *Relish for Chops.*—An ounce of black pepper, half an ounce of allspice pounded fine, an ounce of salt, half an ounce of scraped horseradish, and the same of eschalots peeled and quartered; put these ingredients to a pint of mushroom or walnut catsup; let them steep for a fortnight, then strain them off. A tea-spoonful or two of this mixed with the gravy sent up with chops, or with melted butter, is an agreeable addition.

5078. *Essences, likewise, of the various flavouring substances* may be prepared by procuring their essential oils, and adding them to proof spirit: a few drops of this will answer nearly the same purpose as the fresh herb; but, as they are extremely powerful, they must be employed with a cautious hand, drop by drop, until the article to be flavoured has acquired the proper taste. These domestic essences are now very generally used, on account of the superiority of the flavour they impart, and their economy. The following essences are now kept in the shops: Essence of allspice, bitter almonds, cassia, cinnamon, cloves, lemon, nutmegs, ginger. *Tinctures* may be made by infusing the substances in proof spirit or French brandy: these are superior to the essences. Some examples of these are the following:

5079. *Essence of Lemon Peel.*—Add gradually one drachm of oil of lemons to two ounces of the strongest rectified spirit. A few drops of this will give all the flavour of the rind of the lemon, and is very convenient for punch, blanc-mange, jellies, negus, lemonade, pies, puddings, ragouts, &c.

5080. *Tincture of Lemon Peel.*—Put the rind of lemons into brandy or proof spirit. In a fortnight the tincture will be ready. Tincture of Seville oranges may be made in the same way.

The olio saccharum of lemon may be preserved by rubbing lumps of sugar upon lemon peel, so as to take up the essential oil of the lemon: and these may be kept in a pot, pressing them well down.

5081. *Essence of Pimento.*—Add one drachm of oil of pimento to two ounces of proof spirit. This is very useful in making mulled wine, or gravies: a few drops will suffice.

5082. *Tincture of allspice* is made by steeping three ounces of pimento in a quart of proof spirit, occasionally shaking it during a fortnight.

5083. *Essence and tincture of nutmeg* are made in the same way.

5084. *Essence of Cinnamon.*—Add one drachm of oil of cinnamon to two ounces of rectified spirit of wine.

5085. *Tincture of Cinnamon.*—Steep grated or bruised cinnamon in proof spirit for a fortnight.

5086. *Tincture of celery, thyme,* savoury, marjoram, basil, &c., may be made by steeping these herbs for a fortnight in proof spirit or French brandy. A few drops will be sufficient for flavouring soups, &c.

5087. *Compound essences and tinctures* may likewise be made by exposing two or more of these substances together to the action of spirits.

5088. *The above essences and tinctures are kept ready for sale* in London shops, particularly Fortnum's, Piccadilly.

5089. *Chili Vinegar.*—Infuse fifty red English chilies (cut in half or pounded) in a pint of the best vinegar for a fortnight. A quarter of an ounce of Cayenne pepper added to the vinegar will answer as well.

Chili wine is obtained by putting fifty pounded red chilies into brandy instead of vinegar.

5090. *Basil Wine or Vinegar.*—Fill a wide-mouthed bottle with fresh, green basil leaves, and cover them with vinegar or wine, and let them steep for ten days. If a very strong essence be required, the liquor must be strained off, and more leaves be added to it, to steep in it for another fortnight; when this is done, it must be corked down. When used, a table-spoonful will give to mock-turtle soup the basil flavour.

5091. *Garlic Vinegar or Wine.*—Take a stone jar and put into it a bottle of white wine, half a glass of vinegar, the juice of two lemons, six cloves of garlic, the same number of cloves, the quarter of a nutmeg, and two bay leaves. Put the jar into a kettle of hot water, and set it over the fire; when it boils, cover the kettle close and take it off the fire, and let it stand closely covered near the fire for seven or eight hours; strain it through a coarse sieve; then filter and bottle, keeping it closely corked. A few drops will give a strong flavour to a pint of soup or gravy. A slight flavour of garlic is one of the finest we have; used to excess, it is disagreeable.

5092. *Eschalot Vinegar.*—Eschalots are in high perfection during July, August, and September. Peel and chop a quarter of a pound of eschalots, and pour on them a quart of white-wine vinegar; stop the jar, and let it steep for ten days, shaking it well every day. Pour off the clear liquor into small bottles.

5093. *Eschalot wine* is a more expensive, but a finer flavoured extract of eschalots than the above, and is prepared in nearly the same way. Three ounces of eschalots, peeled and pounded, are infused in a pint of sherry for ten days; the liquor is then poured off, and three more ounces of eschalots, peeled and pounded, are put to it, and suffered to steep in it for ten days longer, when the wine is again poured off and put into bottles, and closely corked. An ounce of scraped horseradish may be added, and the thin rind of lemon.

5094. *Tarragon Vinegar.*—This is an agreeable addition to soups, salad, sauce, and to mix in mustard. A wide-mouthed bottle must be filled with fresh-gathered tarragon leaves. These should be gathered on a dry day any time between midsummer and Michaelmas, just before it flowers. The leaves must be picked from the stalks, and dried a little before the fire, covered with the best vinegar, and steeped for fourteen days; strained through a jelly-bag until fine, and bottled in half-pint bottles; these must be carefully corked, and kept in a dry place.

5095. *Mushroom Catsup.*—Look out for mushrooms from the beginning of September; take care they are of the right sort, and fresh gathered; full-grown flaps are to be preferred: put a layer of these at the bottom of a pan, and sprinkle them with salt, then another layer of mushrooms and some salt on them, and so on alternately, salt and mushrooms; let them remain two or three hours, by which time the salt will have penetrated the mushrooms, and rendered them easy to break; then pound them in a mortar, or mash them well with your hands, and let them remain for two days, not longer, stirring them up and mashing them well each day. Then pour them into a stone jar, and to each quart add an ounce and a half of whole black pepper and half an ounce of allspice; stop the jar close, and set it in a stew-pan of water, and keep it boiling for two hours at least. Pour the juice clear from the settlings through a hair sieve (without squeezing the mushrooms) into a clean stew-pan; let it boil very gently for half an hour. Those who are for superlative catsup will continue the boiling till the mushroom juice is reduced to half the quantity; it may then be called *double catsup.* There are several advantages attending this concentration; it will keep much better, and only half the quantity be required, so that you can flavour sauce, &c., without thinning it. Neither is this an extravagant way of making it, for merely the aqueous part of the water is evaporated: skim it well, and pour it out into a clean jar or jug; cover it close, and let it stand in a cool place till the next day; then pour it off as gently as possible, so as not to disturb the settlings at the bottom of the jug, through a tamis, or thick flannel bag, till it is perfectly clear; add a table-spoonful of good brandy to each pint of catsup, and let it stand as before; a fresh sediment will be deposited, from which the catsup is to be quietly poured off, and bottled in pints or half-pints, which have been washed with brandy or spirit: it is best to keep it in such quantities as are soon used. Take especial care that it is closely corked, or dipped in bottle cement. If kept in a cool, dry place, it may be preserved for a long time; but if it be badly corked, it will soon spoil. Examine it from time to time by placing a strong light behind the neck of the bottle, and if any pellicle appears about it, boil it up again with a few peppercorns

5096. *Walnut Catsup.*—Boil or simmer a gallon of the expressed juice of walnuts when they are tender, and skim it well; then put in two pounds of anchovies, bones and liquor, ditto of eschalots; one ounce of cloves, ditto of mace, ditto of pepper, and one clove of garlic. Let all simmer till the eschalots sink, then put the liquor into a pan till cold; bottle and divide the spice to each. Cork closely, and tie a bladder over each. It will keep twenty years, and is not good the first. Take care to express the juice at home; it is rarely unadulterated if bought.

5097. *Walnut Catsup made of the green Walnuts.*—Bruise one hundred and twenty young walnuts; put to them three quarters of a pound of salt and a quart of good wine vinegar; stir them every day for a fortnight; then strain and squeeze the liquor from them through a cloth, and lay it aside; put to the husks half a pint of vinegar, and let it stand all night; then strain and squeeze them as before, adding the liquor obtained from them to what was put aside the day before; add one ounce and a quarter of whole black pepper, forty cloves, half an ounce of nutmegs bruised or sliced, half an ounce of ginger, and five drachms of mace, and boil it for half an hour; then strain it off from the spices, and bottle it for use.

5098. *Tomato Catsup.*—Take one gallon of fine, red, full-ripe tomatos; mash them up with half a pound of salt; let them rest for three days; then press off the juice, and to each quart add two ounces of eschalots and one ounce of ground black pepper; boil these up together for half an hour; then strain them through a sieve, and put to the juice the following spices: quarter of an ounce of mace, allspice ditto, ginger ditto, nutmeg ditto, one drachm of coriander seed, and half a drachm of cochineal; bruise them all together, and let them simmer together gently for twenty minutes, and strain them through a sieve. When cold, bottle it, and add a wine-glass of brandy to each bottle; cork it, and it will keep good for seven years.

5099. *Oyster Catsup.*—Take some fine fresh Milton oysters, wash them in their own liquor, then pound them in a marble mortar, and to a pint of oysters add a pint of sherry; boil them up, and add an ounce of salt, two drachms of pounded mace, and one drachm of Cayenne; let them all boil up again; skim them, and rub them through a sieve. When cold, put it into bottles; cork, and seal it well. It is best to pound the spice in the mortar with the oysters.

SECT. VIII.—PASTRY.

SUBSECT. 1.—*Preparing Pie Crusts.*

5100. *Pastry generally* is composed of similar ingredients, but which, being differently proportioned and incorporated, form many varieties; such as the *rich*, the *plain*, the *flaky* or *puff pastry*, the *short crust*, &c. In hot weather, a cool place, a marble slab, and cool hands are essential in making good pastry; in the winter it is necessary to render the temperature warmer. The cook, in hot weather, should place the butter to be used in a pan of cold water for a few hours, and, whenever it is possible, the pastry should be made early in the day; the less the hand touches the pastry the better. The flour and water may be mixed together with a wooden pestle, the butter laid on with a knife, and the whole completely united by the use of the rolling-pin. In making pastry, a proportion is always observed between the quantity of butter to be incorporated with the flour, and the number of times the paste is to be folded up and rolled out. Thus, if half a pound of butter to a pound of flour is the proportion, the paste is made up into three folds, and rolled out three *times*, or *turns*, as the cook calls it; if three quarters of a pound of butter is used to one of flour, the paste must have *five turns*, that is, folded in three, and rolled out five times. A pound of butter to a pound of flour will require five and a half or six turns. By half a turn, the doubling the paste, and not folding it in three, is understood. In all pastry very little liquid should be used in mixing the ingredients together; no more than just to form them into a smooth paste.

5101. *Receipt for a rich Meat Pie Crust.*—Make a pound of well-dried flour into a stiff but smooth paste, with very weak salt and water; roll it out on the marble slab or paste-board; take a pound of butter, and lay with a knife a portion of it in patches on the surface of the paste; roll it in three folds, and roll it out again; lay on another portion of the butter, and proceed in the same manner for five times; the butter being thus incorporated with the flour, the paste requires nothing more than to be rolled out the thickness required for the pie. Roll out and put a small piece of the paste in the oven, which, if sufficiently heated, will soon show its thickness, and serve as a test for the rest. When once put into the oven, the door must be closed until the pastry has risen; cold air admitted to the oven while the pastry is rising would cause it to fall and become heavy.

5102. *Plain Meat Pie Crust.*—The proportion: half a pound of butter or beef suet, or dripping, to a pound of flour; the turns, three.

5103. *A Short Pie Crust.*—Rub half a pound of butter into a pound of dried flour, and add a tea-spoonful of finely-pounded sugar. Mix the paste smooth with water, and give it three turns. The suet, or dripping crust, answers for the servants' table, or for that of a family in which economy is an object. A dripping crust requires great care in baking; if the oven is too hot, and it is all burned, the crust is then neither agreeable nor wholesome.

5104. *Crust for Venison Pasty.*—The *crust for venison pasty* is sometimes made like other meat pie crust, the proportion being three quarters of a pound of butter to a pound of flour, half rubbed in, the rest laid on; five and a half turns allowed. Another receipt allows only half a pound of butter to a pound of flour, the paste being formed before the butter is incorporated with it, with the yolks and whites of three eggs well beaten. If these are insufficient to mix it smooth, a little weak salt and water may be added. The dish in which a venison pasty is to be baked must be lined with paste on the sides, but not at the bottom. The lid of the pasty should be thicker than that usually covering a meat pie, in order to stand a long continuance in the oven.

5105. *Standing Crust for Yorkshire Pies.*—Take a peck of flour and six pounds of butter; boil the butter in a gallon of water, and, as it dissolves, skim it off from the surface, taking with it as little of the water as possible; work it well into the flour until a smooth paste is formed, and, when cold, make it up in the usual form.

5106. *Potato Crust.*—Pound some boiled potatoes very smooth, and add, while warm, a sufficiency of butter to make the mass hold together; if not butter, the yolk of an egg will do as well. Then roll on the board this paste to a proper thickness, and put it on the dish while warm; if cold, it will crack. It makes it richer to put both egg and butter into the crust.

5107. *Puff Paste for Patties, Vol au Vents, &c.*—*Puff paste* for any composition requiring a deep border is rarely well made. It depends upon a nice attention to the rolling of the pastry; the number of times which it is *folded* and rolled out is regulated by French cooks according to the proportion of the flour and butter. Thus, to three quarters of a pound of butter to one pound of flour they allow *five turns;* that is, the paste must be folded in three, and rolled out five times. A pound of flour and a pound of butter take five and a half or six turns. When the paste is only doubled, not folded in three, it is called half a turn. Now take a pound of well-dried flour, separating from it as much of it as may be wanted for working the paste; weigh and wash a pound of butter, and put a small piece of it into the flour; take a quarter of an ounce of salt, dissolve it in cold water, and mix the flour with it to a smooth paste. If the butter is soft, put it into a dish, and set it in a pan of cold water until it is of a consistency equal to that of the paste. Dust the board with some of the reserved flour, and spread out the paste as square as possible. Mould the butter, also, into a square, with a floured cloth; lay it in the middle of the paste, and fold the paste over it, so as to cover it entirely; dust it with flour, and roll it out gently, taking care that the butter does not break through the paste, which, if too hard, it will be apt to do. When the paste is rolled out to its utmost extent, fold it up in three, dust it and the table with flour, and roll it out again; this is called two turns. Dust it with flour, and let it lie untouched for a quarter of an hour, after which give it two more turns; then let it lie another quarter of an hour or ten minutes, and roll it out again for the fifth and last time, unless, as before mentioned, the proportion of butter to flour is greater than here directed, in which case it will require half, or a turn more. The last rolling must extend the paste to the proper thickness, as it cannot be rolled out again without injuring it. Have a quick oven for it, and do not open it till the paste is nearly done, or it will fall.

SUBSECT. 2.—*Making Savoury Pies.*

5108. *Rump-steak Pie.*—Cut three pounds of rump steak, sufficiently hung to be tender, into pieces about three or four inches in length; trim off all skin and sinew, and beat the steaks well with the rolling-pin. Chop half a dozen eschalots very fine, and mix a tea-spoonful of black pepper and a tea-spoonful of salt together; spread on the bottom of the dish a layer of eschalot, and sprinkle it with the seasoning; on this spread a layer of meat, then the eschalot and seasoning, and fill the dish in this manner; pour over it a wine-glass of mushroom catsup, and the same quantity of beef gravy or of red wine. Cover it with a moderately thick crust, and bake for two hours.

5109. *Beefsteak Pie, with Oysters.*—Cut from a tender rump a thick steak of about three pounds weight. Fry it slowly in some of its own fat, of a nice brown. Beard three dozen oysters; reserve their liquor, which stir and mix with some beef gravy; distribute the beef and oysters into the pie-dish; season highly with black and Cayenne pepper, but not too much salt. Put in part of the gravy, and cover it with a pretty thick crust of puff paste. Bake it slowly, and if more gravy be required, pour in the remainder some time before it is taken from the oven. *N. B.*—All meat pies should be done in a slow oven, for if they boil fast the meat will be rendered tough.

5110. *Veal Olive Pie.*—Cut off from a fillet of veal as many slices as the number of olives required; make them flat and smooth with the chopper, or by beating them once or twice with a rolling-pin. Rub each over with beaten yolk of egg; cut thin slices of fat bacon the same size as the veal; lay it on the veal; rub that with egg also: have a veal forcemeat ready (see "Forcemeat"), and spread it scantily over the bacon; roll the whole up tight, and cover the surface with egg and bread crumb. Line the pie-dish with paste, and put in the olives, covering them with some good gravy. Let it bake two hours; have a gravy ready thickened with cream and flour, and pour it into the pie before it is served.

5111. *Ham and Veal Pie.*—Cut some thick slices from a leg of veal, divide them into convenient pieces, and make an incision into each piece to introduce a thin slice of lean ham well seasoned. Put at the bottom of the pie-dish some light forcemeat, composed of the fat of the ham, beat with the panada herbs and yolk of egg (see "Forcemeat"); make also some balls of the same, which poach and distribute between the layers. Add plenty of seasoning, pour in veal gravy, and cover the dish with a thick puff paste. Bake, and before it is done, introduce some additional gravy. In the same manner ham and chicken pie may be made; but in the latter instance some cream should be worked into the veal gravy.

5112. *Venison pasty* is best made with the neck and breast of venison. Take out the bones and stew these with the trimmings in sufficient beef stock, a bunch of parsley, green onions, and an eschalot; add two glasses of port wine. In this liquor braise the pieces of venison till they are half done, when they are to be put into the pie-dish, and seasoned with salt, pepper, and allspice; strain, and clear the gravy from fat; cover with a thick puff paste, and reserve some of the gravy to supply that which is consumed. A slice of raw ham considerably improves the flavour of this pasty.

5113. *Mutton Pie.*—Cut into chops, trimmed neatly from all fat, off the best end of a neck or loin of mutton. Lay them in a dish, and season them with pepper and salt; add a wine-glass of mushroom catsup, some chopped onion, and sliced potatoes; cover it with a crust (see " Pastry"), and bake it for two hours. When done, lift up the crust, and pour out the gravy to cool, so as to remove the fat; then boil it up, and pour it into the pie again.

5114. *Small Mutton Pasties.*—Cut the paste the size of a mutton chop; season and shred some garlic over each, and, if not very fat, add a small piece of fresh to each. Cover them with a crust, and bake them in a moderately quick oven. These small pasties serve to make out a dinner, and are very relishing when nicely dressed.

5115. *Pork Pies.*—Cut the meat left after trimming flitches that are being prepared for salting into small pieces, together with trimmings from the griskins, and the meat from the sweet bone. Keep the fat and lean separate, and season both with pepper and salt; then raise the crust (see receipt for), and, when ready, fill the pies closely with layers of lean and fat, those of the lean being of greater depth than the fat layers. Unite the lids firmly to the sides, and bake the pies in a soaking oven, the meat, being solid, requiring this; put no water or gravy into the pies.

5116. *Rabbit Pie.*—Stew in clarified butter some parsley, mushrooms, a table-spoonful of green onions chopped, and an eschalot minced; when tender, put in a couple of rabbits properly divided, and let them stew about a quarter of an hour. Take them out, and put them into a raised earthen pie-dish, sheeted with paste. Drain the butter from the vegetables, and put them into the pie with plenty of seasoning and some veal gravy, or, which is better, some gravy obtained from rabbits. Put a paste cover to the dish with a hole in the top, to suffer the steam to evaporate, and also to introduce some fresh gravy as the other consumes. Bake it till done. *N. B.*—Never put water into a meat pie, but always gravy, as the water dissolves the nutritious parts of the meat, and leaves it tasteless, so that the whole of the savour is in the extracted gravy.

5117. *Giblet Pie.*—Clean and half stew two or three sets of geese giblets; cut the leg into two, the wing and neck in three, and the gizzard into four pieces; preserve the liquor, and set by the giblets till cold, as the heat of the giblets would spoil the paste which covered them. When cold, put them into the dish, season and salt them, and cover them with a good butter and flour paste. (See " Pastry.") Cover the surface with the yolk of egg, and bake it an hour and a half in a moderately heated oven. Take away the fat from the liquor in which the giblets were stewed, and in a clean stew-pan set it over the fire with a little flour and water, seasoned with black pepper and salt, and flavoured with lemon juice; add a few drops of browning, and, when hot, pass it through the tamis, or sieve, and afterward, by means of a funnel, into the pie. Into a giblet pie some put a beefsteak, or remnants of cold game or poultry.

5118. *Pheasant Pie.*—This is to be eaten cold. When you have a superfluity of game, pick and empty a couple of pheasants, clean the insides well, and pepper them thoroughly. Stuff the insides with a bunch of parsley, an onion or two, some trimmings of mushrooms, and truffles, if you have them. Put a piece of the fat of ham on the breasts of each, and half roast them. When removed from the fire, empty their insides of the herbs, which stew with some veal broth for their gravy. Cover them with paste, and bake them, with the precautions before directed. In the same manner proceed to make pies of moor-game and partridges. Observe to press the birds flat, and bake them with the backs uppermost.

5119. *Pigeon Pie.*—When pigeons are plentiful and cheap, you may afford a couple to make the gravy for the pie. When emptied and washed, divide these two pigeons, and mash them, bones and all, in a mortar; put some parsley, trimmings of mushrooms, and truffles, if you have any, with green onions and some salt, into butter, to stew gently; when tender, put in the mashed pigeons, and, when they have well sweated, moisten with some veal broth, so as to possess, after the gravy is completed, rather more than a pint, which strain, and skim off the fat. Put into a pie-dish, sheeted with paste, a veal cutlet, and over it six pigeons, both well seasoned; distribute some egg balls (see "Forcemeats"), and fill up the dish with part of the prepared gravy; then apply a paste cover of a good thickness. Bake it, and, as the gravy exhales, fill up with the remainder. *N.B.*—This pie requires to be well seasoned, and eaten hot. If you make a pigeon pie to be eaten cold, you may cover the bottom, sides, and top with slices of bacon, as, when cold, the fat may be removed. If you prefer beefsteak to veal at the bottom, it may be substituted.

5120. *Trout Pie.*—This is to be eaten cold, and is nearly as good as potted char. Take a dozen of small trouts, from a quarter to half a pound; empty them, and detach the fins. Parboil them in salt and water, and lay them on a hair sieve to drain, and put them in a very slack oven for a few minutes to become dry. When they are taken out, brush them over, inside and out, with clarified butter, and have ready a mixture of salt, black pepper, Cayenne, and allspice, with which season them, likewise, both inside and out. Pour some clarified butter at the bottom of the earthen dish, and arrange the trout in it; then pour in more of the butter until they are covered. Set them in a moderate oven for half an hour, or till they are sufficiently done, and suffer them to cool. In this manner they will keep some time.

5121. *Eel Pie.*—When the eels are skinned and cut into pieces about two inches in length, blanch them, by pouring on them sufficient boiling cider with some salt, or, if this be not at hand, some vinegar, salt, and water of the same temperature. This hardens them, and extracts a portion of their oil; when cold, take them out, and place them in a sheeted pie-dish; add a little salt, shred lemon peel, and black pepper. Cover them with a sauce composed of equal parts of veal gravy and thin cream. Let it bake gently, and the eels will eat firm.

Subsect. 3.—*Savoury Patties.*

5122. *Of savoury patties, the first consideration is the pastry*, which should be made according to the directions already given under the head *Puff Paste.* The tin moulds being lined with the paste, and the covers neatly cut out (the surface of which must be brushed over with beaten egg), pieces of crumb of bread sufficient to support the cover are put into each, and they are baked in a moderately brisk oven until they become of a yellowish brown. If the oven be too hot, they should be covered with a sheet of paper. When baked, the cover is taken off, the bread removed, and the inside filled with some savoury composition. The cover is replaced, and the patties are ready to be served. Sometimes they are made without covers; if this method be adopted, it is necessary to make a depression, or hollow, in the middle sufficient to contain the savoury composition.

5123. *Lobster Patties.*—The meat of boiled lobsters is set over the fire with some strong veal consommé, a little flour to thicken, some eschalot chopped fine, an anchovy pounded, and a little grated lemon peel. After these and a seasoning of Cayenne pepper are put in, the whole must simmer together for five or six minutes, and when taken off the fire, some lemon juice must be added and stirred in well. The patties are then filled, and served hot. *Oyster patties* are made in the same way, the oysters being previously chopped.

5124. *Patties of ham and chicken,* finely mixed, may be made of a lean boiled ham and the breasted and white meat of roasted fowl; to these are added eschalot, a slice or two of truffles stewed till tender in wine or gravy, and afterward chopped fine, some veal consommé, a little cream, Cayenne pepper, salt, and flour to thicken the gravy. After simmering these over the fire for a few minutes, the patties may be filled. Lemon juice, if added, must be put in at last, after the composition is withdrawn from the fire.

5125. *Patties of forcemeats,* such as those compounded of sweetbreads, herbs, and panada, or any other light forcemeat, must be united with the yolk and white of egg, and baked in the patties. When baked, the covers must be removed while some strong consommé or bechamelle is added.

5126. *Patties of game* may be made of any cold pheasant, partridge, or woodcock, finely minced with eschalot, mushrooms, and truffles, and seasoned with Cayenne. To these may be added either sauce velouté or bechamelle, with flour to thicken. After simmering for a few minutes, this savoury meat may be put into the patties.

SECT. IX.—COOKING VEGETABLES.

For a description of the vegetables, see Book VII., Chap. VIII.

5127. *Potatoes.*—These should be selected of the same size, because, if boiled together, the small ones will be overdone and the larger remain hard. Let them be pared, and put on in cold water, by which they get gradually heated; they should boil very slowly; fast boiling breaks them, and lets in the water. Feel with a fork when they are done enough. When they are sufficiently boiled, pour the water from them, throw in some salt, cover them with a napkin to absorb the vapour that may arise, and put them by the side of the fire to keep hot. Some prefer cooking them by steam. *Potatoes half boiled* may be sliced and broiled, or they may be fried until they acquire a nice brown. *Potatoes three parts done* may be put into the dripping-pan to receive the drippings from the meat; in this way they are excellent, and, at the same time, economy is consulted. *Potatoes roasted* in the Dutch oven, or baked, do not require paring, but only to be well cleaned. *Potatoes mashed* after they have been boiled ought to be beaten smooth in a mortar or potato-masher, and mixed with the yolk of an egg and cream, or, if you have no cream, with hot milk and some butter; add salt, and put them in either dish or scollop shells, or they may be warmed in a sauce-pan, constantly stirred. The surface may afterward be browned with the salamander.

5128. *Cabbage and Greens.*—All the cabbage tribe, which includes cauliflower, brocoli, coleworts, sprouts, and turnip tops, in order to be delicate, should be dressed young, when they have a rapid growth; but if they have stood the summer, they require to have felt the influence of the frost to become tender. In order to appear green at table, they must be boiled in hard water. Greens of the above description, when of advanced growth, are better flavoured when boiled in two waters, which is managed in the following manner: After they have been about half boiled, take them out of the pot, place them in the colander, and allow cold water to run on them for two or three minutes; then replace them in a fresh pot of boiling water, with some salt, and let them continue to boil briskly till done. Cauliflower should boil more slowly, as it is apt to be broken by the force of a violent ebullition. Brocoli, to be freed of its offensive odour, should always be boiled in two waters.

5129. *Carrots,* when young, require to be simply boiled till they are sufficiently tender, which may be known by passing a fork into them; but during the winter they are apt to become in parts hard and stringy; when they are in this state, they may be cut into lengths convenient for boiling, and their internal and stringy part, which is very indigestible, may be scooped out by a small gouge.

5130. *Turnips* are seldom served whole, but, after they have been boiled, are sent to table mashed. When stringy, they must be passed through a coarse sieve. In order to mash them, let the water be well pressed from them; add sufficient butter, salt, and pepper, with a little powdered white sugar, which much improves their flavour. A little flour mixed with the butter renders the turnips less watery when mashed.

5131. *Spinach*, after being well picked, may be boiled in water with some salt; or it may be put into the sauce-pan and boiled in the juice which itself affords. When done enough, let the water be pressed from it, and, when put into the dish, divide it into squares. Spinach, when boiled, may be finely chopped and mixed in a stew-pan with some cream previously heated; add some pepper, salt, and a little powdered sugar. If you prefer a slightly acid flavour, add a tea-spoonful of lemon juice after it is removed from the fire. Avoid stewing spinach in butter, as the heat it communicates renders it crisp and destroys its colour. Fried toasts are usually served round the dish when spinach is stewed in this manner.

5132. *Asparagus and Sea Kale.*—The latter requires simply boiling over a brisk fire. Asparagus, when properly scraped, and cut of a uniform length, is tied up in bundles and boiled. A toast moistened in some of the liquor is sent up with both, and they are eaten with melted butter, salt, and pepper. When the asparagus is young, and so slender that it is not fit to be brought to table dressed whole, the green tops and more tender parts may be cut into pieces and boiled till more than half done, in salt and water; let them drain, and when you have melted some flour and butter in a small stew-pan, moisten with a spoonful or two of veal consommé, to which add a lump of sugar; next work the yolk of an egg and some cream into the sauce; put in the pieces of asparagus, and let them boil for two or three minutes. Serve it up in a dish garnished with fried toasts. You may occasionally vary this dish by adding green onions and chopped parsley to the asparagus.

5133. *Cucumbers.*—A fresh-gathered cucumber requires to be pared and thinly sliced; put the slices for about a quarter of an hour into cold spring water. Before you dress them, take them out and let them drain on a napkin for a minute; put them into a dish, and add oil, vinegar, and plenty of Cayenne and black pepper. Sprinkle them, of course, with a little salt. Cucumber thus dressed is now eaten with boiled fish, as turbot, salmon, and mackerel. *Another way of dressing cucumbers* is to cut them into slices about the thickness of a crown piece, and let them soak in vinegar and salt for half an hour. When taken out, dry them with a napkin, and fry them in butter of a very light brown; take them out of the pan when sufficiently done, and let them drain before the fire. To the butter in which they have been fried add some flour, and incorporate them well; moisten this with veal gravy and the yolk of an egg; work the sauce well, and, when reduced to a proper consistence, season it and pour it over the fried slices of cucumber.

5134. *Green Pease.*—According to the English fashion, they only require to be gathered young and dressed on the same day. They ought to boil fast; mint may be put with them, or omitted, as it may be most agreeable. A few taken out of the pot with a spoon, and tasted, will indicate when they are done enough. When properly drained in the colander, have ready a couple of pie-dishes made hot, into one of which put the pease, with some pieces of butter, and cover it with the other; then invert the dishes four or five times, that the butter may be equally distributed among the pease, and serve them up hot.

5135. *Windsor beans*, when young, are to be simply boiled, and served up with parsley and butter. When old, the external skin may be taken off after they have been boiled, and the green part well mashed over a gentle fire, adding butter and a little flour, chopped parsley, pepper, and salt. You may cover the top with grated Parmesan cheese, and apply the salamander, or you may include in the mashed beans some pieces of boiled bacon, cut into such shapes as may be most approved.

5136. *French Beans.*—In order to have them green at table, they should be gathered young, and trimmed, stringed, and divided. Boil them fast in water, with some salt. Do not divide each bean into more than four pieces, as they lose their flavour when shred, and become watery. All French beans should be of the same growth; for, if the young be mixed with the old, they will be unequally done.

5137. *Salad.*—The component vegetables of a salad are very numerous, and there are various modes of dressing it. Whatever may be selected should be fresh gathered, scrupulously washed, and it should lie for some time in cold spring water. Let it be trimmed for the table, so that there may be no cutting off any refuse parts when brought to it. To be in perfection, a salad should be eaten the moment it is dressed; if it soak in the materials, it becomes vapid and flaccid. It is always best to have the materials ready mixed to pour on the salad. If mustard be employed as one of the ingredients, it ought to be made the day before. The vegetables, when taken out of the water, should be properly drained; this is best effected by swinging them in a clean napkin, together with gentle pressure; when dripping wet they dilute the vinegar, which should be strong and sparingly used. As many persons cannot digest a mixture of boiled egg with mustard, oil, and vinegar, the two former may be omitted: indeed, the best and most elegant salads are composed of two parts of oil, with one of strong vinegar, and a sprinkling of salt; in winter a small quantity of Cayenne pepper may be added.

SECT. X.—PUDDINGS, TARTS, AND SWEET DISHES.

SUBSECT. 1.—*Puddings.*

5138. *Plain Family Rice Pudding, baked.*—Put into a pie-dish rice washed and picked, in the proportion of a quart of milk to four table-spoonfuls of rice, one of moist sugar, some grated lemon peel, a stick of cinnamon, and two or three small pieces of cold butter. Let this bake in a slow oven for three, or even four hours. The milk must be new, or it will curdle.

5139. *Another Receipt for baked Rice Pudding.*—Boil for a quarter of an hour a pint of milk and half a pint of cream, with a piece of lemon peel and cinnamon; sweeten it with powdered loaf-sugar; strain it, and set it on to boil for the same time, with two ounces of ground rice. When cold, stir into it three table-spoonfuls of oiled butter, four eggs beaten, a glassful of noyeau, and some grated nutmeg; sheet some puff paste round the rim of the dish, and bake it gradually.

5140. *Rice Pudding, boiled.*—Take half a pound of *Carolina* rice; steep it in milk for half an hour, that is, put it into cold milk, and set it by the fire to warm gently and slowly. If too quickly done over a hot fire, the swelling of the rice is checked. When cold and stiff, tie it up in a pudding-cloth, and boil it for an hour in water. Serve it with sweet sauce of melted butter and sugar, flavoured with lemon peel and lemon juice.

If a richer pudding be required, three or four eggs may be added to the rice after it has been steeped, and then it may be boiled either in a cloth or basin.

5141. *Rice and Apple Snow-balls.*—After steeping rice in milk, apples, peeled and cored, may be boiled in the centre of the pudding. Currants and raisins, in the same way, may also be mixed with the rice.

5142. *Ground Rice Pudding.*—Mix four table-spoonfuls of ground rice very smoothly in a few table-spoonfuls of cold milk; boil a pint of new milk, and mix it with the rice as smoothly as possible, beating it well together. When cold, add to it the yolks of four or six eggs (according as the pudding is required to be rich or otherwise), and the whites of half the number; pound three bitter and half a dozen sweet almonds with sugar; grate some lemon peel, and, if liked, some nutmeg also; butter a dish, and bake in a quick oven for half an hour, or boil in a basin for the same time. Turn it out, and serve with white wine sauce.

5143. *Puddings of millet, sago, tapioca, and arrow-root* are also very wholesome and elegant. The whole art of making them consists in incorporating these different farinaceous substances in the first instance with milk, in which they are to be boiled; then sweeten to the palate; after which, when they are cold, add beaten eggs and some powdered spice, as cinnamon, nutmeg, or cloves infused in brandy.

5144. *Batter Pudding.*—Take six eggs, a pint of new milk, half a pound of dry flour, and a little salt; beat up the eggs with the milk, and by degrees sift in the flour till the whole quantity is incorporated; add a little powdered cinnamon or grated nutmeg; boil it in a basin an hour and a quarter. To be eaten with a sauce composed of melted butter, sugar, and lemon juice; wine may be added, if agreeable.

5145. *Pancakes and Fritters.*—*For pancakes,* break three eggs in a basin and beat them up with a little salt, put to them four ounces and a half of flour, mixing them together with milk until the whole is brought to the consistency of good cream. Have a clean frying-pan, not too large; make it hot, and to each pancake put in a piece of butter the size of a walnut. When the butter boils, pour in the batter until the bottom is covered, and fry them on both sides of a light brown. Serve them one by one, or roll them up and send up three or four together.

For fritters, make the batter rather thicker, adding a spoonful more of flour to it. Peel either apples or lemons, take out the core and pips, and slice them; pour a tea-cupful of batter into a pan of hot lard, and lay a slice of apple or lemon in the centre; pour a little more batter on it, and fry of a light brown on each side. Various kinds of fruits may be fried in fritters besides apples.

Rice Fritters.—Steep a quarter of a pound of rice in a small quantity of milk, and fry it with butter in thin cakes. Serve with sweet or wine sauce.

5146. *Plain Fruit Puddings.*—These are a common family dish: they are usually boiled, and are prepared by sheeting, wholly or partially, a basin with pudding paste, and the vacancy filled with any kind of green or ripe fruit. Care must be taken that the crust does not burst or detach to let in the water. When sufficiently boiled (and the time required will depend on the state of ripeness in the fruit, the green occupying much longer) a hole may be cut in the top, by which they are to be sweetened before they are sent to table.

5147. *Apricot or Greengage Pudding, baked.*—Boil ripe apricots or greengages, in sufficient water to cover them, till they are tender; then take them out and rub the pulp through a hair sieve; sweeten it sufficiently. Beat half a pound of this pulp with a quarter of a pound of Naples biscuits, to which add six eggs, a pint of cream, and a pinch of salt; when well incorporated, sheet the rim of the dish with puff paste, and bake gently till done. In the same manner puddings may be formed of the pulps of ripe peaches, nectarines, egg-plums, or of any ripe fruits from which a pulp may be obtained.

5148. *Lemon Pudding.*—Pare thinly and boil the external rinds of three lemons; beat these in a mortar with loaf-sugar, an ounce of blanched almonds, and half a pound of Naples biscuits; beat up six eggs with a pint of cream, and mix all well together; add some powdered cinnamon or grated nutmeg; edge the rim of the dish with puff paste, and bake it gently. In the same manner you may make an orange pudding, by substituting their rinds for those of lemon.

5149. *A Plain Pudding.*—Line a pie or pudding dish with thin slices of bread and butter. Peel, core, and slice some apples; lay them in layers in the centre of the lined dish, adding here and there a small lump of fresh butter, some grated lemon peel, and sugar; fill up the dish, and lay at the top some thin slices of bread and butter soaked in cold milk. Cover the top with a plate or dish, and put a weight on it to press down the fruit. Bake it for three hours in a slow oven; an hour before it is done, remove the weight and dish, and let it brown on the top. When done, turn it out of the pie-dish to the one on which it is to be sent to table.

5150. *Tansey Pudding.*—This is with many a favourite in the spring. Bruise sufficient tansey to obtain three table-spoonfuls of its juice; pour this on as much crumb of French roll as will imbibe it. Pound three ounces of blanched sweet almonds to a fine paste with two ounces of loaf-sugar, the same quantity of butter, and a tea-spoonful of grated Seville orange peel. Beat up a pint of cream with six eggs, and mix all the ingredients thoroughly together. This pudding may be either boiled or baked; if the former, it requires a sauce of melted butter, sugar, and lemon juice.

5151. *Rich Plum Pudding.*—The excellence of this depends equally on the mixing and boiling. Pound to a fine paste two ounces of blanched almonds, and mix them with eight egg yolks and whites beaten up together; add a pint of cream; into this stir a pound of sifted flour, a pound of raisins stoned, the same quantity of currants picked, and a pound of suet very finely chopped. Add sufficient sugar, with spices, some candied orange peel or citron, and a couple of glasses of cherry brandy. Boil it five hours. This pudding may be baked, if you prefer it.

5152. *Plain Plum Pudding.*—Stone half a pound of raisins, clean very well half a pound of currants, chop finely half a pound of beef suet, grate a pound of bread crumbs, pound a few bitter and sweet almonds, and shred a little candied peel; mix these thoroughly together, and moisten them with milk; put the whole either into one mould, or into three small ones. Boil the large one for four or five hours, the small for three.

5153. *Suet Pudding.*—Take beef suet, chopped fine, and flour, of each half a pound, three eggs, whites and yolks well beaten together; mix these with as much milk as will be required to make it of a proper consistence; add some salt and a little powdered allspice; tie it firmly in a cloth, and boil it thoroughly.

5154. *Marrow Pudding.*—Pour gradually a quart of boiling milk on half a pound of Naples biscuits and the same quantity of chopped marrow; mix them well together, and let them cool; when cold, beat up six yolks of eggs and the whites of two only, which stir into the other ingredients; add a handful of currants picked and washed, thin slices of candied citron, and a little powdered cinnamon; sheet the sides and rim of the dish with puff paste, and bake it.

Subsect. 2.—*Apple Tart.*

5155. *Peel, core, and quarter* eight or ten russet apples or lemon pippins; lay them closely in a dish, adding lemon juice if the apples are not very sharp, and lemon peel and sugar. Some cooks put in two or three cloves, others quince marmalade; but as the flavouring ingredients are not always liked, they are better omitted. Cover the dish with puff paste, and bake an hour and a quarter.

5156. *Cranberry Tart.*—Take and wash a quart of cranberries in several waters; put them into a baking-dish, with the juice of half a lemon and a quarter of a pound of moist or powdered lump sugar. Cover them with puff paste, and bake three quarters of an hour. Five minutes before it is quite done, ice it (see "Icing") and return it to the oven.

5157. *Rhubarb Tart.*—If the rhubarb has a green spotted surface, it is a kind that may be cut up without peeling; if the red sort, the peel must be torn off before it is cut up in pieces of an inch in length. Fill a dish with these, adding sugar and lemon peel, and, after covering it with a puff or short paste, bake it for three quarters of an hour.

5158. *Icing for Fruit Tarts.*—Beat up to a froth the white of two eggs, and when the tart is nearly baked, with a paste brush cover the crust with some of the white, and sprinkle it over with some finely-powdered lump sugar; wash the brush, and splash the sugar very gently with water till it is dissolved. Put the tart again into the oven for five minutes longer.

Subsect. 3.—*Cheese-cakes.*

5159. *Curd Cheese-cakes.*—Incorporate a quart of curd with half a pound of butter in a soft state, half a dozen macaroons, three yolks, and the white of one egg. Sweeten it sufficiently, and put in a pinch of salt and some grated lemon peel. When all these are well beaten together in a mortar, sheet some tartlet moulds with puff paste, put some of the mixture into each, and bake them quickly. If you please, some currants and candied orange peel may be added. Some are partial to the flavour of noyeau. These puddings may be either boiled or baked; when intended for the latter, they are improved by the addition of a little oiled butter. Some add perfumes, as rose or orange flower waters.

5160. *Lemon Cheese-cakes.*—Grate the rind of three and the juice of two lemons; mix them with three sponge biscuits, six ounces of fresh butter, four of powdered sugar; add some pounded cinnamon and nutmeg, and mix the whole well together with three well-beaten eggs and a glass of cream. Sheet the patty pans with puff paste (see "Pastry"), and fill them with the mixture, laying on the surface of each cheese-cake thin shreds of candied peel.

5161. *Orange Cheese-cakes.*—Orange cheese-cakes are made in the same way, orange juice and rind being employed instead of lemon.

5162. *Almond Cheese-cakes.*—Blanch, dry, and pound with rose or orange flower water very fine, six ounces of *sweet* almonds and half an ounce of *bitter;* reduce to a cream with a spoon half a pound of butter, and mix the almonds with it, adding six ounces of powdered sugar, some grated lemon peel, a quarter of a pint of cream, and four beaten eggs. Fill the patty pans, sheeted with puff paste, and bake in a quick oven for half an hour; put candied peel on the tops of each cheese-cake.

5163. *Mince Meat.—Take two pounds* of beef suet finely chopped and picked free from strings, *two pounds* of apples peeled and chopped small, *two pounds* of raisins stoned and chopped, *two pounds* of currants washed and thoroughly cleansed, one pound of good moist sugar; boil three lemons, and, after pounding the rinds small, add them and the juice to the other ingredients; chop small half a pound of candied citron and lemon peel, and work all these ingredients together with two wine-glasses of French brandy, and a little salt. Put them into a covered jar, which place in a cool spot, and the mince meat will keep for several weeks. Keep at the top of the jar some unchopped candied peel, and add a slice to each mince pie, when any are being made. Some prefer puff paste, others a short crust, for sheeting the pans.

Subsect. 4.—*Creams and Custards.*

5164. *Cream for Tarts.*—Mix together half a pint of cream and the same quantity of milk; put into it a piece of fresh lemon or Seville orange peel, a little cinnamon, and sweeten it with loaf-sugar. Let them boil about ten minutes. Have ready prepared in another pan the yolks of six eggs, well beaten up with a heaped tea-spoonful of fine flour; to these gradually strain the boiled ingredients, and whisk them well together over a gentle fire, so that they may acquire the proper consistence without curdling. If you are deficient of cream, milk only may be employed, but in that case a little more flour will be required. When cold, it may be distributed over tartlets or pies.

5165. *Cream another Way.*—Take a pint of cream mixed together in equal proportions, as in the last receipt; boil it with some lemon peel and cinnamon, and sweeten it to the palate; beat up the yolks of eight eggs with a table-spoonful of rose or orange flower water and a little salt. Mix these with the boiled cream when strained, set the whole on the fire, and keep constantly stirring with a wooden spoon. When the cream has acquired the proper consistence, lay it on a hair sieve to drain.

5166. *Cold Custards.*—Pound to a fine paste two ounces of blanched Jordan almonds, with half a dozen of the bitter ones, and two ounces of loaf-sugar; moisten with a little milk, and add a few grains of salt. When it becomes of the consistence of a thick cream, take it out and beat it up with the yolks of eight eggs; then gradually add a pint of half milk and cream; set this on a very gentle fire, with a couple of bay leaves, and continue to stir it till it acquires the proper consistence, when it is to be removed immediately and distributed into glasses. Some persons, on the supposition that they are unwholesome, omit the bitter almonds and bay leaves, and substitute the perfumes of rose or orange flower waters, or a little vanilla.

5167. *Blanc-mange.*—Simmer together a quart of half cream and half new milk, with some cinnamon, a few coriander seeds bruised, sufficient sugar, and a bay leaf; to these add an ounce of picked isinglass, and, when it is dissolved, strain the mixture. Set it by to cool, and if any film arise on the surface, skim it off. When nearly cold, pour it into the moulds.

To dissolve Isinglass.—This substance is indispensably necessary for jellies, ices, creams, and a variety of other preparations of dessert. Let the isinglass be of the best quality, and properly beaten; of this put a quarter of a pound into a pint of water moderately warm, and let it continue covered, in a heat below boiling, stirring occasionally till it is dissolved. This will be a very firm jelly, and will readily dissolve in any warm fluid. The confectioners who employ ice in their jellies prepare a weaker solution, by adding four ounces of the isinglass to six pints of water, which they reduce by boiling to two quarts; it is then strained.

5168. *Syllabub.*—Whisk well together a quart of cream, two glasses of French brandy, a pint and a half of sherry, with a table-spoonful of strained lemon juice, and sufficient powdered loaf-sugar to render it agreeably sweet. As the froth is produced, collect it with a spoon, and lay it on a sieve to drain; continue to whisk it till no more froth is produced. To the remaining liquor grate some nutmeg, fill the glasses half full with it, and at the top add an equal portion of the froth.

5169. *Trifle.*—This is a compound of syllabub and sweetmeats. Line the bottom of a glass trifle-dish with sponge biscuits stuck with blanched almonds; moisten them with sweet wine, or with sherry and sugar. Over these lay a dozen of ratafia cakes dipped in noyeau. Intersperse with these some thin slices of citron and orange peel, and distribute over these pieces of apricot and raspberry jam with currant jelly. Pour over these a few spoonfuls of the liquor of the syllabub. The next layer should consist of tartlet cream (see "Tartlet Cream") of about the thickness of an inch, over which grate some nutmeg, and strew a little powdered cinnamon, together with a small quantity of grated lemon peel and some powdered loaf-sugar. Lastly, take the whipped froth from the sieve, and put it on the top as abundantly as the dish will contain. To give it a pleasing appearance, strew variously-coloured comfits over the froth.

5170. *Gooseberry Fool.*—Stew a quart of green gooseberries with a little water till tender, and pass the pulp through a tamis. When nearly cold, add the juice of a lemon, sweeten it with powdered loaf-sugar, and dust in equally about two tea-spoonfuls of flour. In the mean time, boil a pint of new milk with some beaten cinnamon, lemon peel, and bruised coriander seeds, till it becomes impregnated with the flavour of the spices; sweeten it to the palate; then strain the milk, and mix it well with the yolks of four eggs beaten up. Whisk them over the fire to prevent curdling, and continue this till it begins to boil, when it is to be removed. When cold, mix it with the pulp of the gooseberries, and grate some nutmeg on the top. The same method may be pursued with the pulps of ripe apricots, strawberries, and raspberries, always remembering to add the lemon juice, which considerably improves the flavour.

SUBSECT. 5.—*Jellies.*

5171. *Calves' Feet Jelly.*—Take out the bones from the calves' feet, divide them into pieces, and throw them into warm water to soak out all the blood. After this wash them well in cold water, and put them into a stew-pan with sufficient water, that is, to four feet put five quarts of water; let them simmer gradually, and remove all froth and scum as it rises. When they are nearly dissolved, and the water reduced by boiling to half its quantity, which takes five or six hours, strain them hot through a fine silk sieve, and if any fat remain, remove it entirely. Put the strained liquor again on the fire in a clean stew-pan, sweeten it with loaf-sugar, add the peels and juice of lemons and some cinnamon. Mash four eggs, shells and all, which put in, and whisk it well with a clean rod, till it begins to become white and form bubbles; let it then continue to simmer about half an hour longer, when it may be removed from the fire, and strained through a flannel bag. This operation of straining must be repeated till it is perfectly transparent. If you wish to introduce any wine into the jelly, let it be put in with the eggs and spices. Madeira is the best, and if you require it of a deep tint, some liquid of colour may be added.

5172. *Fruit jellies* in the summer time are very salubrious, and are made at little expense. Such fruits as abound in juice are best adapted for these preparations.

5173. *Strawberry Jelly.*—Mash with the hand a quantity of fresh-gathered strawberries; squeeze the juice through a cloth, and put this liquor, with sufficient sugar and lemon juice, into a pan over a gentle fire, and skim it well from froth; when clear, add some melted isinglass, and strain it through a flannel bag. Repeat this till it is transparent, and, when nearly cold, put it into moulds. Some whole strawberries may be put in before the jelly concretes. This is the most difficult to make of all these jellies, as the fine aroma and flavour of the strawberry become dissipated by heat.

5174. *Cherry Jelly.*—Take two pounds of Kentish cherries and half a pound of blackhearts; stone them; mash the cherries and pound the stones; mix them together, and let them simmer about half an hour with some cinnamon and a few bruised coriander seeds. Strain them through a sieve. Set them again on the fire, with sufficient sugar, and the juice of two lemons; remove any scum that may arise, and add sufficient melted isinglass; strain it, till clear, through a flannel bag, and, lastly, pour it into the moulds. In proportion as the juice of these fruits is diminished by evaporation, the less isinglass will be necessary. If required particularly transparent, whites of eggs must be put in; and whenever the person preparing these can have access to ice, the process is much facilitated.

5175. *Raspberry Jelly.*—Express the juice of the raspberries, and let it simmer, removing all scum till about a third is consumed; add lemon juice and sugar, or, which is better, clarified sirup, as it produces no additional scum; with this mix sufficient isinglass previously dissolved, and, when nearly cold, pour it into the moulds. In the same manner, jellies may be made from any of the fruits that abound in juice, as barberries, currants, white and red, grapes, oranges, and lemons. In proportion as the juices are evaporated, they will require less isinglass to form them into a jelly. The addition of lemon juice, the quantity of which must be adjusted by the palate, and also the sugar, very considerably improves the flavour.

5176. *Currant Jelly for Sauces.*—This may be made of the white, red, or black currants. The red is mostly used in cookery. Pick red currants, and express their juice, which boil in the preserving-pan until a third part is consumed, removing all scum that may arise. While hot, strain this juice through a flannel bag. To a pint of this juice add a pound of fine loaf-sugar powdered, and, when it boils, carefully remove any scum; let it continue to boil about half an hour, when it may be poured into pots. Prepared in this manner, by previously concentrating the juice, it will keep for a long time, if preserved in a dry place.

5177. *Another Way (without boiling).*—Put red currants, stripped of their stalks, into a stone jar; cover it close, and put the jar either into an oven or into a kettle of hot water, by which means the juice may be completely expressed, the fruit being only just swelled by the heat. While hot, strain the juice through coarse muslin, and pour it into a china bowl, after ascertaining the number of pints of juice thus obtained; to every pint add a pound of loaf-sugar broken into very small lumps. Put the bowl in a cool place, and occasionally, in the course of every day, stir the sugar and juice together, for two or three weeks, when they will begin to jelly sufficiently, though not so firmly as when boiled in the usual way. The advantage of this mode is its economy, no waste of juice occurring as it does when boiled for a sufficient time. It is, however, firm enough to be used for sweet sauce.

BOOK XIV.

FRENCH COOKERY.

CHAPTER I.

FRENCH AND ENGLISH COOKING COMPARED.

5178. *Among the distinctive characteristics of French cooking*, the first that obtains notice is that which arises from the long-continued, although gradual action of heat to which all solid meats under the hands of French cooks are submitted, and by which all the fibrous parts are brought into a state of perfect incineration. In English cooking, the time allowed for roasting or broiling, and even for boiling, is, in all general cases, limited, in the apprehension of a French cook, to such a degree as to render English dishes scarcely eatable; as food for semi-barbarians, not for a civilized people. The English imagine that more genuine flavours and greater nourishment are to be found in their dishes than in those of the French; the latter, on the other hand, assert that in English cooking too much is left for the digestive organs to perform. The state of incineration into which solid food is reduced by French cooking is that into which the digestion must bring it before it can complete its operations; and as in English cooking this is not, according to French notions, sufficiently brought about, it is regarded as the cause of the frequent derangement of the digestive organs, and consequent hypochondriacal affections common to the English.

5179. *Another characteristic in French cooking* is the variety of flavours which it can impart to any single meat. From the long-continued action of heat allowed by French cooks, the juices of meats are almost entirely extracted to form the basis of *soups*, together with the *gravies* of various dishes, to each of which a variety in flavour may be given, the original one of the meat being so intermingled as to be scarcely distinguishable. In this way French cooking yields an almost endless number of dishes, prepared from a few original substances, which, by the art either of *braising*, *marinading*, or *poëling*, may be impregnated with any peculiar flavour the cook may desire to produce. The addition of an appropriate sauce, or purée, completes the effect, and determines also the name of the dish, whether it be "fowls *aux Truffes*," "fowls *à la Mirepoix*," or "fowls *à la Perigord*."

5180. *In English cooking* no flavour is considered to be equal to the one peculiar to each meat. Beef, mutton, or venison would, at the English table, be considered as having lost their distinctive excellence if, in the cooking, their genuine flavour were interfered with. Whatever condiment or sauce is employed as an accompaniment to each meat, it is always of such a modified nature as not to overpower that flavour which is peculiar to the meat, the juice of which, when, in a well-roasted joint, it issues from the opening made in carving, is considered as far excelling any which the cook can compound.

5181. *Again, French dishes* have always had a decided advantage over the English in appearance; they are made to please the eye as well as the taste. No heavy masses of viands are served at a French table; but light, elegant, and tempting forms are presented to those around it. In this respect the English cooks are beginning to reform their style, and to study, in serving, neatness and elegance in the arrangement of the contents of each dish.

5182. *In the last place, the economy of French cooking* must be noticed, and with approbation. In its various processes nothing is wasted; every particle has a use and consequent value. The flavour and richness of the meats are not obtained by any expensive means or prodigal use of them, but are the results of the modes of cooking skilfully followed. In English cooking the maxim that "good dishes can only be formed out of good and abundant materials" is often carried to the utmost length in practice. Many ingredients in the English kitchen are cast aside, or reserved as the cook's perquisites, which in the French kitchen would be brought into use, and would render needless the employment of more expensive ingredients. In this slight comparison of these two principal systems of cooking, it may, perhaps, be perceived that from each might be transferred to the other useful and valuable modes, favourable to the enjoyment of the table and to the economical use of food.

CHAPTER II.

FRENCH COOKING TERMS AND PROCESSES EXPLAINED.

Atelets.—Small silver skewers.

Assiettes.—Dishes with four compartments for chopped herbs, parsley, eschalots, &c., to which, being in the kitchen always at hand, the cook can resort at once. The chopped ingredients are prepared by the under assistants.

Bain Marie.—A large flat vessel containing boiling water, in which dishes already prepared can be kept hot. See a wood-cut of this vessel, *fig.* 684, p. 829.

Braising consists of stewing without much moisture any article in a seasoning of carrots, onions, parsley, thyme, bay leaves, and cloves.

Buisson is a high-standing remove on a dish of pastry dressed high.

Compôte.—A fine mixed ragout to garnish white poultry, or to serve as entrées. Fruit also stewed with sirup for dessert is termed *compôte.*

Compotice.—The deepest dish appropriated to the *compôtes.*

En couronne.—To place or dress the articles of a dish in the form of a crown.

Crustades.—Bread baked in moulds, and hollowed out to receive farces of different kinds.

Croutons.—Bread cut out in shapes and fixed in oil or butter; these are ornaments of some of the mirotons and other made dishes.

Dorey.—To cover pastry with yolks of eggs. *Dorures* are yolks of eggs well beaten.

Desseites.—Things left at table untouched, and afterward used up in forming farces and salpiçons, &c.

Dormant.—A centre dish, allowed to remain during a whole dinner.

Entrées.—Dishes served at the first course.

Entremêts.—Dishes served at the second and third courses.

Emincé.—A mince of some kind of meat.

Feuilletage.—Puff paste.

Friture.—A frying-pan.
Farce à quenelles.—Forced, or farced meats.
Glaze.—Reduced consommé, used to cover the meats of made dishes.
Glace.—White of egg beaten with powdered loaf-sugar.
Godiveau.—A veal forcemeat.
Au gras.—When a dish is to be dressed with meat gravy.
Gratiner.—To make the surface crisp of any dish, and to give it a grilled taste.
Hors d'œuvre.—A small dish served during the first course.
Lardons.—Meat cut for larding.
Larding.—Meat, poultry, &c., having lardons of bacon or other articles drawn through the flesh by means of the larding pin.
Larding pin is an instrument as sharp as a needle at one end, and like a port crayon at the other. The lardon is entered at the square and open end; the sharp end is then passed through the meat, and in drawing the instrument out, it is so contrived as to release the lardon from its hold, and which is left drawn into the flesh of the article to be larded.
Liaison.—A thickening for soups and gravies, formed of yolks of eggs.
Au maigre.—Soups prepared without meat.
Marinade.—A pickle into which meat, fish, or poultry is put for several hours, sometimes for days, previous to its being cooked. A marinade is composed of different flavouring ingredients combined with vinegar, sometimes with oil, according to the dish to be prepared.
Au naturel.—Anything simply boiled.
Nouilles.—An Italian paste resembling macaroni, but flat instead of being piped.
Noix de veau.—The large and fleshy part of the leg of veal attached to the udder.
Passer.—To fry lightly.
Pigné.—Larded on the surface only.
Panieres.—Everything dressed with a coating of crumbs of bread and egg.
Poëling.—Take a pound of beef suet, one of fresh butter, one of very fat bacon; cut the suet and bacon into large dice, and put them in a stew-pan with two pounds of veal, cut in the same manner; fry them till the veal becomes white; moisten with three pints of clear boiling water, a handful of salt, a bay leaf, a few sprigs of thyme, an onion stuck with cloves, and a bundle of parsley and green onions. Let the whole boil quietly till the onion is done; strain it through a sieve, and set it by for use. Poële is employed to make everything boiled in it look white, and to acquire a relishing taste; it will keep for a week. Do not boil any lean of bacon with it, or the meat boiled in it will turn red from the saltpetre used in curing the bacon. Poëling and braising are almost the same operation; but in poëling meat must be underdone, in braising overdone.
Potage.—Soup, or broth.
En Poule.—A particular way of trussing a fowl for the spit.
Purée.—Meat, fish, or vegetables boiled to a pulp and passed through a sieve.
Ravigôte.—A sauce.
Au rosette.—To dress a dish in the form of a rose.
Salmi.—A highly-flavoured dish.
Salpiçon.—A dish made of equal quantities of any and all sorts of meat and vegetables; these are minced and cooked separately, and warmed together when ready to serve.
Sauté.—To fry lightly.
Singer.—To put flour into the stew-pan.
Sabotier.—Tin utensils containing sand, in which are placed the moulds that are to be put into the ice-house to be frozen.
Tamis.—A silken sieve.
Toppot.—The fat from the water in which meat has been boiled: it is much used in French cooking.
Vanner.—To take up a sauce and turn it over quickly with a spoon.

CHAPTER III.

RECEIPTS FOR FRENCH COOKERY.

SECT. I.—SOUPS AND SAUCES.

5183. *Grand Consommé.*—Put two knuckles of veal, part of a leg of beef, a fowl, a rabbit, or two old partridges; add a cupful of soup, stir it well, and when it jellies, add two quarts of clear stock; boil and skim it carefully, season it with three turnips, three carrots, three onions, one stuck with two or three cloves, a bunch of leeks, and two heads of celery. Let it then simmer for four hours; strain it through a sieve, or tamis, into a clean earthen pan, and set it in a cool place for use.

5184. *Consommé of Poultry.*—Veal and ham, with the trimmings of poultry, are the basis of this consommé. The flavouring ingredients are mushrooms, parsley, and green onions. Veal broth or stock, sufficient to keep the vessel full, must be added, and the whole, after boiling, must be gently stewed for two or three hours. The broth will be more savoury and mellow if the meat be not overdone. The fat must be skimmed off, and the consommé strained through a silken sieve.

5185. *Consommés of Game.*—Entrées of partridges must be prepared with consommé of partridge, made from veal and from the backs and other trimmings of partridges and rabbits. If the entrées are served with truffles, the consommés must be *flavoured* with truffles and mushrooms, together with a bundle of parsley and green onions. The whole must be moistened with consommé (containing ham), and must then be boiled, but not over much, strained, and set by for use.

5186. *White Roux for thickening white Sauces.*—Put into a sauce-pan a lump of butter; melt it over a slow fire, and separate, by draining, the residue of butter-milk contained in the butter; dredge it with flour till it is of the consistency of paste; keep it on the fire for a quarter of an hour, but take care not to let it colour; pour it into an earthen pan ready for use.

5187. *Brown Roux.*—Put butter into a stew-pan, and proceed as above directed for white roux; fry the paste of butter and flour over a slow fire, till, by very gradual steps, it becomes finely coloured; when of a light-brown, pour it into an earthen pan ready for use: it will keep for some time.

Sect. II.—Potages.

5188. *Potage à la Reine.*—Take three chickens or pullets; skin them, take out the lungs and clean them; lay them in a stew-pan with a bunch of parsley only; moisten the whole with boiling broth; stew for an hour, and take out the chickens. Soak the crumb of two penny rolls in the broth; pound the meat of the chickens with the soaked bread, and three or four yolks of hard-boiled eggs. Rub the whole through the tamis, or sieve. Boil a quart of cream, stirring it all the time, and pour it on the soup; it is not so likely to curdle, if done in this way, as by the usual mode of mixing it, while cold, with hot liquids. To this soup rice or vermicelli may be added, but either must be previously stewed in some broth, the rice for some time, the vermicelli for five or six minutes only.

5189. *La Brunoise—Winter Soup.*—Blanch carrots and turnips cut into dice; add to them as much rich broth as the number of the party may require. Season it with salt; add a little sugar to it; boil the whole for an hour. Skim off the fat, and serve with mitonnage of crusts.

5190. *Potage à la Condé.*—Take a quart of French beans, put them into a stew-pan with two quarts of consommé, a pound of bacon, three carrots, three onions (one of them stuck with cloves), a bunch of leeks, two heads of celery. Let all simmer together for three hours. Take out the vegetables, pulp them into the soup, and again boil all together. Fry bread in dice, and serve in the soup.

Sect. III.—Removes (after fish and soup).

5191. *Beef (à la Flamande).*—Take the brisket or part of the rump of beef. Season it with carrots, onions, parsley, bay leaf, and cloves. Boil it gently four hours. Drain away and reduce the liquor to a glaze. Cover the beef with it when served. Garnish the dish with carrots and turnips braised, also with cabbage done separately. Serve it with Espagnole sauce. (This dish may be sometimes garnished with cucumbers, farcé, or with Spanish onions glazed, or with artichoke bottoms.)

5192. *Braised Leg of Mutton.*—Put a leg of mutton into a braising-pan, with trimmings of veal, and with carrots, onions, and a bunch of parsley; also a few green onions properly seasoned. Cover the whole with thin slices of bacon, to keep them from burning. Stew all for four hours. Strain through a sieve, and afterward reduce to a glaze the liquor. Glaze the mutton, and serve with glazed onions.

5193. *Calf's Head (de fruits certain).*—Bone a calf's head. Make a farce of veal, bacon, and sweet herbs finely chopped. Mix them together with two yolks of eggs. Stuff the head with the farce, and secure it by sewing up the head. Wrap it in a cloth, and put it into a braising-pan, with several slices of veal and bacon. Season it with carrots and a bunch of parsley, thyme, bay leaf, and a blade of mace. Moisten it with one glass of white wine and a ladleful of broth. Let it stew for four hours, and serve it with a financiere. Boil a glass of Madeira, and put it into the sauce, which should be highly seasoned.

5194. *Fowls à la Montmorencie.*—Take a couple of fine fowls; prepare them as if for boiling, taking away also the breast bone. Put lemon juice, salt, and a little butter into the body; lard the breast. Line the stew-pan with bacon, and lay the fowls in, covered with a poële made in the following manner: Cut into dice a pound of veal, another of bacon, and a small piece of the fat of ham. Fry them white in half a pound of butter. Moisten with water; season it with parsley, salt, pepper, thyme, half a bay leaf, and one clove. Stew it for some time over a slow fire; strain it over the fowls, which stew for three quarters of an hour. When done, drain and glaze them of a fine colour. Garnish with larded sweetbreads, and serve with ragout à l'Allemande for sauce.

5195. *Fowl à la Monglus.*—Take a cold, roasted fowl, and remove the breast and fleshy parts away from the back bone and side bones. Put into the fowl either an emincé or a salpiçon (see terms explained). Beat the yolks of two eggs, and cover the fowl with them, strewing over it afterward crumbs of bread. Brown it lightly in a Dutch oven, or by a salamander. Serve it with a brown sauce if the inside be stuffed with a salpiçon; but if with an emincé, a veloutè sauce must be used.

The salpiçon may be made of dressed fowl, tongue, truffles, and mushrooms, cut into dice, and warmed up in sauce Espagnole. When cold, use it as above directed. Salpiçon is always used with brown sauces.

Emincé may also be made with meat of dressed fowl or game, minced extremely small, and warmed up in béchamelle sauce well seasoned. With an emincé a white sauce is always used.

5196. *Removes of Ham.*—Soak a Westphalia ham for twelve hours; a Westmoreland, unless very highly dried, for half that time. Boil it for two hours; then drain, skin, and trim it; put it into a braising-pan, lined at the bottom with thin slices of veal, and seasoned with carrots, onions, parsley, bay leaf, and spices. Pour over it two glasses of rich consommé and a bottle of Madeira. Let it boil for two hours more. When done, pour out some of the liquor and reduce it, after skimming off the fat, to an Espagnole, the sauce to be served with this dish. Of the rest of the liquor make glaze, and serve the ham immediately on taking it out of the braise.

5197. *Westphalia Ham à l'Essence.*—Saw off the knuckle of a small Westphalia ham, taking care not to splinter the bone. Soak it one day in water, to draw out the brine. Boil it in plain water four hours. Drain it, remove the rind, trim it, giving it a nice round form. Dry the fat from it for a few minutes in the oven, that the glaze may be properly given to it. Serve under it sauce à l'essence.

5198. *Remove of Beef Tongue.*—Take a pickled tongue; boil it for three hours. Peel off the skin while hot, trim, and glaze it. Serve it with mashed turnips on one side, and with mashed carrots and spinach on the other.

Sect. IV.—entrées.

Subsect. 1.—*Entrées of Beef.*

5199. *Miroton of Beef.*—Cut into neat slices some rump of beef, either cooked previously, or fresh. Put the slices into a frying-pan, with sauce *Espagnole* or *brown Italienne.* Give them a few boils, and serve hot; keep the meat always well covered with the sauce, or it will become black and dry.

5200. *Mirotons of Palates of Beef* (*à la Ude*).—Cut the palates and some truffles into equal sizes. Dress them *en miroton* (that is, boil them with sauce in a frying-pan). Take mushrooms, all of nearly one size, to make a border round the dish; put in the middle a salpiçon of truffles, mushrooms, and beef palates. Add sauce Espagnole to the miroton. Let every article to be used be prepared before the dish is made up—palates and truffles, alternately, to the very top. Remember to keep the whole hot, or it will become dry.

Subsect. 2.—*Entrées of Mutton.*

5201. *Cutlets of Mutton*—(*purée of Mushrooms*).—Divide the best part of a neck of mutton into cutlets, trimming each neatly. Season each side of the cutlets with pepper and salt, and with a paste-brush cover them with yolk of egg; dip them into melted butter, and then into bread crumbs. Press the crumbs firmly on the meat, and again dip them into the bread crumbs. Make each cutlet equal and neat with the knife, and put them into the frying-pan with butter. When dinner-time is at hand, fry them over a brisk fire of a very good colour. If the fire be not quick, the cutlets will take too much time in browning, and will be dried up. As soon as they acquire the right colour take them out of the pan. Press each cutlet between clean pieces of whity-brown paper, to drain the fat from them. Glaze them, and put round them a purée of mushrooms.

5202. *The inside of Fillet of Mutton marinaded—au Chevreuil.*—Have the fillets of four saddles of mutton, producing eight *filets mignons.* Lard them, and put them into a marinade pickle; namely, of thyme, parsley, bay leaves, onions, salt, pepper, and vinegar. After being in this pickle for two or three hours, put them into a frying-pan over layers of bacon, and bake them of a nice colour. Glaze, and serve them with a poivrade under them.

Subsect. 3.—*Entrées of Veal.*

5203. *Grenadier de Veau*—(*purée of White Celery*).—These are small fillets of veal, larded as fricandeau of veal, cut thinner than for fricandeau, and consequently requiring less time in cooking. After larding them, put them into a stew-pan with a carrot, a large onion, a root or two of parsley, a bay leaf, and some thyme, a small quantity of mace, allspice, and whole pepper; let the vegetables be at the bottom of the stew-pan, and cover them with layers of *fat* bacon (*lean* bacon will turn veal red); the veal must be laid on them and sprinkled with a little salt. Pour some broth upon the vegetables, but not enough to reach the meat. Close the stew-pan, and put it on a slow fire; cover the lid with hot coals or charcoal, and when it begins to boil, put it over a slow and equal fire for two hours and a half, basting it frequently with the liquor. After this, put a great deal of fire over it to harden the bacon. Reduce to a glaze the liquor, and serve it with a purée of white celery.

5204. *Scollops of Sweetbreads, with Green Pease.*—Wash and blanch four sweetbreads. Cut them into large scollops. Put them into a frying-pan with melted butter and a little salt. A quarter of an hour before dinner is served, fry them of a very light brown over a clear fire; turn them, that they may be equally done; drain away the butter, and put a little glaze into the pan, in which keep stirring the scollops. Put the pease in the middle of the dish, and place the scollops en miroton around them. Scollops of sweetbreads are easier to arrange when a slice of fried bread cut round is put between them, without which they seldom keep the form in which they are first dished.

N.B.—All entrées of veal, such as currés, fricandeaux, cotelettes, sweetbreads, &c., with all sorts of purées; and in the summer with la Macedoine. They are all dressed nearly in the same manner; but by changing the sauce, the flavour and appearance are changed also.

SUBSECT. 4.—*Entrées of Tongues.*

5205. *Miroton of Pickled Tongue.*—Cut some thin slices of cold pickled tongue; dress it en miroton in a dish, and put it into an oven for ten minutes. Put mashed turnips in the centre of the dish, and glaze the tongue.

5206. *Stewed Beef Tongue (unsalted).*—Take a fresh tongue, wash it, and blanch it in hot water. Stew it in a good braise for two hours and a half, skin it, and cut it in two; spread it open, and mash with sauce machée.

5207. *Miroton of Tongue, with Sorrel Purée.*—Take slices of tongue stewed as above, and dress it en miroton; highly glaze it, and serve with sorrel purée.

SUBSECT. 5.—*Entrées of Fowl.*

5208. *Fowl à la Villeroi.*—Take a fine fowl, empty, singe, &c., and truss it with its legs turned outward; put in the inside a small quantity of butter kneaded with salt and lemon juice. Put the fowl into an oval stew-pan, with a layer of fat bacon; pour some poële over it. While entrées are not to be kept longer on the fire than needful, three quarters of an hour will dress a fowl in this manner; a capon perhaps an hour. Serve it with sauce à la financière.

5209. *Scollops of Fowls.*—Take the fillets of three fowls. Cut each scollop of the size of half a crown; dip each in clarified butter, and fry them on both sides over a brisk fire. Put them into the sauce prepared for them; if truffles, cut the truffles about the same size as the meat, and fry them with the scollops of fowl. A few minutes before dinner put them all into a béchamelle sauce, into which a reduction of truffles has been added. The reduction is prepared with trimmings of truffles, put into and stewed in consommé till it becomes a glaze. This glaze is stirred in with the scollops, and, to make it white, a few spoonfuls of thick cream must be added. In preparing this or any other meat with truffles, care must be taken to do both meat and truffles thoroughly. Both the meat and truffles may be fried together; but the meat must be taken out first, and the truffles must be allowed to remain in a little longer, and be very equally fried on both sides. The scollops are then put in a second time; the butter is drained away from them, the truffle sauce added, and the meat allowed to lie in it for an hour, that it may fully imbibe the truffle flavour. The sauce must be kept thick: it may be thinned at any time. Though the meat and truffles must be well done, they must not be over-fried. It is the most difficult point in French cookery to know the precise time required by the various articles which are frequently combined. Experience only can give this excellence to cooks.

5210. *Scollops and fillets of fowl* may be dressed with any of the under-named sauces and purées; with maréchal sauce, Espagnole, béchamelle, essence of cucumbers, sauce Allemande; with oysters, truffles, mushrooms, purées of green pease, of celery, and cucumbers.

Each sauce gives its name to the dish of which it is the accompaniment, or prepared with it, as, scollops of fowl—à l'Espagnole, à l'Allemande.

5211. *Chickens à l'Ivoire.*—Pick and singe two chickens well, thrust the hand inside, and remove the breast bone. Mix together some butter, the juice of half a lemon, some pepper and salt, and put some of the mixture into the body of each chicken; bind them up neatly, lay them in a stew-pan surrounded with layers of bacon, and cover the breasts of the chicken with thin slices of lemon and bacon. Pour some poële over them, and stew them for half an hour. They should be perfectly white, and served with velouté or béchamelle.

5212. *Chickens à la Villeroi* are dressed in the same way, but served with aspielié or maréchal sauce.

5213. *Curry.*—This may be made of chicken, lobster, veal, or mutton. When of chicken, let a couple be divided into pieces convenient to distribute at table; blanch them in hot water, and stew them gently till half done in some veal stock with a table-spoonful of curry powder. Next prepare the sauce, which consists of a couple of moderately-sized onions, sliced, a table-spoonful of curry powder, some butter, and flour; work this well over the fire; moisten with the liquor in which the chicken has been stewed, with additional veal stock; put in the chickens, and let them simmer till done, when they are to be taken out and kept warm. Pound two ounces of sweet almonds to a paste, and incorporate it with the sauce; remove any fat, season it with Cayenne pepper and lemon juice, and pour or strain it hot to the chickens. When veal, lamb, and mutton are employed, they should previously be fried of a light brown. For preparing the rice, see "Vegetable Entremêts," Sect. VII., Subsect. 2.

SUBSECT. 6.—*Entrées of Partridges and Pheasants.*

5214. *Partridges à l'Espagnole.*—Let it be remembered that old partridges are unfit for French dishes: they may be dressed with purées of lentilles, or employed in the game consommés or cold patties. The young ones only can be introduced as entrées, and may be known by the white tinge at the sharp extremity of each wing; when that mark is observable, the birds will be found tender enough for use. Truss three partridges (see "Directions for Trussing," &c.), put them between layers of bacon, and pour a poële over them. Over a slow fire stew them for twenty minutes; dish, and pour over them an Espagnole, to which some glaze of game has been added to give it a game flavour.

5215. *Young Partridges à la Montmorenci.*—Empty and truss young partridges; dip the breasts into boiling water, and immediately after into cold, to make them firm. Lard them with slits of bacon, and put them into a stew-pan surrounded with slices of bacon. Immerse only one half of the birds in poële or other liquids. Over a brisk fire stew them for twenty minutes; glaze them, and probe them in the back; if no blood issues they are done sufficiently. Drain them, and glaze a second time. Serve with ragout *à la financière.*

5216. *Partridges à la Crassandine.*—After emptying and picking the birds, cut off the claws, make a hole below the joint of the leg, truss the leg inside the body, singe the birds over a flame till the flesh becomes firm, pinch the breast with your left hand, scollop the breasts without reaching the skin, turn the flesh over on the table, beat the bird flat, dust it with salt and pepper, dip it twice in clarified butter and crumbs of bread, broil it, and serve it with an Italienne, or essence of game.

5217. *Soufflé of young Partridges.*—Pound the meat of roasted partridges in a mortar, seasoning it well, and adding to it a few spoonfuls of velouté and a lump of butter. Mix with this the yolks of four or five eggs, and strain the whole through a sieve; beat the whites of the eggs, and mix them also, but lightly, with the *purée.* Bake the whole in a soufflé-dish for twenty minutes. Prevent it from burning at the top by covering it with paper.

5218. *Salmi of Pheasants.*—For this dish roast the pheasant only half an hour. When cold, cut it up as if for eating. Put the parings into *sauce à salmi.* If two pheasants are thus prepared, do not use the legs, except for flavouring. Cut each side of the breast into three slices, and fry the same number of slices of bread of equal size; the meat put into a covered stew-pan to prevent it drying. Now prepare the sauce by frying together a small bit of lean ham, four eschalots cut small, some parsley roots, a carrot cut in dice, some thyme, a bay leaf, six cloves, mace, ten grains of allspice. Add either brown sauce or a spoonful of flour, two glasses of Madeira, and a ladleful of veal gravy. Season with salt and pepper, put in the trimmings, and boil all together; skim off all the fat, and, if it taste bitter, add some sugar. Keep the sauce thick enough to cover the meat, over which pour it through a tamis, and warm both together without boiling them. This dish may be made with truffle sauce by adding to the sauce the trimmings of truffles, and by boiling some truffles cut neatly in sauce by themselves. Put the truffles in the middle of the dish when it is served.

Subsect. 7.—*Entrées of Rabbits.*

5219. *Rabbits à l'Orlie.*—If large, the rabbits must be filleted; if small, marinaded in joints; the small bones to be taken out and put into the preparations of game consommé. Detach the fillets of four rabbits, and marinade them for two hours in lemon juice, parsley, thyme, eschalot cut in pieces, bay leaf, salt, and pepper. Drain, and dip them in white of egg well beaten, and into flour mixed with a few crumbs of bread. Fry of a fine brown, and serve under them a poivrade or Espagnole of game.

5220. *Scollops of Rabbits and Truffles.*—Detach the fillets of five rabbits, and tear off the sinews; scollop the fillets, keeping the knife on the slope; with the handle flatten the scollops, and put them into the sauté-pan with melted butter; peel and slice some truffles of the size of the scollops, and mix them with the rabbits; butter, salt, and pepper. Fry lightly twenty minutes before serving, and leave the scollops in the sauce to imbibe the flavour of the truffles. Garnish the dish with a conté.

5221. *Blanquette of Rabbits, with Green Pease.*—Detach the fillets of four rabbits, soaking them whole in melted butter, with seasoning of salt and pepper; cut them on a sheet of paper the size of a shilling, and put them into the sauce à blanquette aux pois. This entrée may be sent up in a vol au vent, or casserole of rice.

5222. *Rissoles of Rabbits.*—Make *fine farce* of the remnants of roasted rabbits; make a light, but not rich, puff paste, and roll it out; cover at equal distances the paste with lumps of the farce, moisten the paste round the farce, fold it over in two, press the paste with the fingers to make it adhere, cut it with a rowel, and fry it till it is of a fine brown colour. If dipped in egg and covered with bread crumbs, they will fry of a better colour. Serve with fried parsley in the middle of the dish.

Subsect. 8.—*Entrées of Hare.*

Hare is in England most commonly served as a remove, but may also be introduced as entrées, either in boudins, quenelles, or minces.

5223. *Fillets of Hare (with blood).*—After skinning two hares, thrust the knife along the spine, taking care to bear towards the bone. Tear with your fingers the fillet from the neck down to the legs; leave the thick fleshy part to the leg: introduce the sharp side of the knife to the tender part of the fillet, and the thumb towards the skin; press your thumb on the sharp side of the blade, that it may not cut the part containing the sinews; then pull the fillet towards you, and the sinews will remain attached to the leg. Lay the fillets on the table, and flatten them with the knife. Lay them in a sauté-pan with melted butter, and dust over them salt and pepper. When it is dinner-time, fry the fillets, and scollop them. Put them into sauce de civet made of the remnants of the hares; add to it the blood of bot hares, that the sauce may be of a dark brown.

5224. *Fillets of Hare en Chevreuil.*—Take fillets of hare, and lard them with bacon ; put them into a deep vessel, with salt, pepper, parsley, two onions cut into slices, a bay leaf, some thyme, a glass of vinegar, and half a glass of water. Let the fillets marinade in this two days ; then put them into a sauté-pan, bake them underdone, and glaze with a light glaze. They are always dark enough without the colour being deepened by the glaze. Serve with poivrade sauce under.

Subsect. 9.—*Entrées of Quails.*

5225. *Compôte of Quails.*—Quails are fashionable, rather from their rarity and expense than from their real excellence. A white compôte of quails is made in the same manner as compôte of partridges, the only difference being in the use of broth of veal instead of gravy. Thicken the same with yolk of eggs, and serve the onions white, the same as mushrooms.

5226. *Quails, with Pease.*—Put into a stew-pan six quails moistened with a poêle, or with two spoonfuls of broth, a bunch of parsley, a bay leaf, some thyme, one clove ; stew for twenty minutes over a slow fire. Drain them, and let them boil for a moment with pease and bacon. Next dish the quails, reduce the pease, and mash with them.

5227. *Quails à la Crassandine.*—These are dressed as pigeons or partridges, à la crassandine. Serve them with an Italienne, or a consommé à glace over them.

Subsect. 10.—*Entrées of Woodcocks.*

Woodcocks and snipes are cooked in very few ways. The most delicate parts are the legs and intestines. They may be cooked in as many ways as young partridges. A purée of woodcocks is also occasionally served.

5228. *Salmi of Woodcocks.*—This operation is the same as a salmi of partridges. Covered with paper, the birds are roasted, but not browned. They are then cut up, and the whole of the skin removed. Put them into a stew-pan to get cold, and prepare the sauce for them with the trimmings of the birds and four eschalots, some slips of ham, a carrot cut in dice, three or four mushrooms, a little parsley root, a bay leaf, some thyme, a clove, eight grains of pepper, and the same of allspice. Fry these in a stew-pan with butter, and, when slightly browned, add three glasses of Madeira, six spoonfuls of Espagnole, and two of consommé. Put in the parings of the birds, but not the claws, and stew them slowly for an hour and a half; skim the sauce, and add a small bit of sugar, and strain it through a tamis : lade the salmi hot with slices of fried bread cut in shapes, and glazed.

Subsect. 11.—*Entrées of Pigeons.*

5229. *Compôte of Pigeons (brown).*—Pigeons are less used as entrées than as garnitures; but are occasionally useful as entrées in intermediate seasons, when game and young poultry are not to be had. For a compôte of pigeons, take four or six, according to the size of the dish ; pick them clean, and cut off the sinew below the joint of the leg ; draw them, without taking out the liver, but carefully removing all grain from the craw. Truss the legs inward, and make an incision in the back that they may disgorge ; put them into warm water to draw out the blood : then cover them with bacon, and stew them as chickens. Drain them, and serve with a ragout à la financière.

Subsect. 12.—*Entrées of Wild Ducks.*

5230. *Wild Ducks, with Orange Sauce.*—Cut out the fillets of three wild ducks; give them a few slight cuts on the skin side, marinade them for an hour in oil, with young onions broken in two, branches of parsley, salt, large pepper, and the juice of mushrooms. Immediately before they are to be served, put them into a frying-pan with two spoonfuls of oil; set them over a good fire, turning them two or three times ; drain, and arrange them in the dish in the form of a crown, and serve under them orange sauce.

5231. *Wild Ducks, with Green Pease.*—Prepare and cook the ducks as above; and make the sauce in the following way : Put two quarts of fine green pease into a pan of clean water, with half a pound of fresh butter, mixing it with the pease ; drain the pease by taking them in the hand out of the water. Let them dry, and put into a stew-pan a small bit of fresh butter and half a pound of the best part of a breast of bacon, cut into squares of an inch in size. Fry them of a nice colour, and, draining away the fat, put in the pease to sweat ; when green, add to them half a spoonful of flour, and moisten with boiling water. Put in the members of the duck, and, when it has stewed sufficiently, serve it covered with pease. Remember to skim off the fat very carefully.

Subsect. 13.—*Entrées of Larks.*

5232. *Larks au Gratin.*—Take eighteen fine larks ; pick and bone them ; season with salt and pepper, and stuff them with *farce fine.* Put them into a dish with some of the farce between them, and ornament the birds with fried bread cut into fanciful shapes, and put between the birds. In arranging the birds round the dish, if any remain, raise them in the middle above the rest ; cover them with slices of bacon, and bake them for twenty minutes ; remove the bacon when done, drain away the fat, and serve with an Espagnole of a good colour and well seasoned.

Sect. V.—Stuffings and Farced Meats.

Subsect. 1.—*Panadas.*

5233. In this department of cooking the French particularly excel, and their superiority in a few niceties which will be fully explained. The usual fault of stuffing is its want of tenacity; so that, when served up, it falls to pieces; and this arises from the materials being insufficiently mixed. In order that these preparations may be served in perfection, the cook must have the use of a large marble mortar, with a smooth lignum vitæ pestle. The materials of stuffing consist of panada, or prepared bread, meat, and herbs, with adequate seasoning. These are to be mixed up and incorporated with sufficient yolk and white of egg to bind them together, so that the mass may admit of being boiled, roasted, or fried. This farced meat is employed for the stuffing of poultry, hares, and various joints; it is also rolled into balls, which are to be regarded as essential to many dishes, and especially required in meat pies. In order to prepare the *panada*, soak a French roll in milk till it is thoroughly moistened, then press the milk out of it through a clean cloth. Put this squeezed bread into a clean stew-pan with some vegetables, as parsley, green onions, and button mushrooms, chopped fine; moisten these with a couple of spoonfuls of veal stock, and over a slow fire work them well together with a wooden spoon. When the bread is nearly dry, put in a small piece of butter, and continue to work it for a few minutes longer, then remove it from the fire, and mix it well with the yolks of two eggs. This panada is the basis of the farced meat, and, when quite cold, is to be mixed with the pounded animal substances, as scraped veal, ham, chicken, or sausage meat. These are to be beaten well together in a mortar, and made to combine and adhere together with yolk and white of eggs beat up, to which sufficient seasoning is to be added. To ascertain if it be of the desired consistence, roll a small piece in a little flour, and put it into boiling salt and water for a couple of minutes; if it remains firm, it is sufficient; if not, add the yolk of another egg. The French employ calves' udder beat to a paste, in order to render the stuffing more compact; but this may be omitted, as the udder is not always to be procured, and the animal substances above mentioned answer the same purpose when sufficiently beaten in the mortar. The general principle for the preparation of stuffing having been thus explained, the farced meat may be compounded of any materials you may think fit, and varied as occasion may require; for the flavour of farced meat should be adapted to the viands, the zest of which it is intended to increase. Some dishes require delicately, others full and high-flavoured forcemeat. What would be piquante in a turkey would be insipid with turtle.

Forcemeat balls must not be larger than a small nutmeg. If intended for brown sauce or meats, flour and fry them; if for white, put them into boiling water for three minutes.

Subsect. 2.—*Flavouring or Seasoning Ingredients.*

Common thyme.	Black and white pepper.	Yolks of hard-boiled eggs.
Orange thyme.	Allspice, mace, or cinnamon.	Mutton, beef, veal, suet, or marrow.
Lemon thyme.	Ginger, nutmeg, cloves.	Calf's udder or brains.
Sweet marjoram.	Capers and pickles, minced or pounded.	Parboiled sweetbread.
Summer and winter savoury.	Savoury powder, soup-herb powder.	Veal, minced and pounded.
Sage, tarragon, chervil.	Curry powder, Cayenne.	Potted meats.
Burnet, basil, bay leaf.	Zest.	Meat gravy.
Truffles and morels.	Flour.	Lemon juice.
Mushroom powder.	Crumbs of bread.	Sirup of lemons.
Leeks, onions, eschalots, garlic.	Parsley.	Essence of anchovies.
Lemon peel, and essence of.	Spinach.	Mushroom and walnut catsup.
Shrimps, prawns, crabs.	Boiled onions.	Whites and yolks of eggs.
Lobsters, oysters, anchovies.	Minced potatoes.	Wines.
Dressed tongue, ham, bacon.		

Subsect. 3.—*Quenelles.*

5234. *Quenelles of Veal.*—Take half a pound of any fleshy part of veal; cut it in slices, and scrape it from the sinews with a knife. Boil a calf's udder in the stock-pot, or in plain water. When cold, trim away all the upper part; cut it in small pieces, and pound it till it will pass through the sieve. Make the pounded veal into one ball, the udder into another, and of an equal size make a third ball of the panada. The object in making these balls is to ascertain the quantity better. Pound the three balls together; the more they are pounded, the more delicate are the quenelles. Break two eggs' whites and yolks together, and pound them in also, with a seasoning of pepper, salt, and pounded spices. Roll in flour a small ball, and poach it in boiling water to try its texture; if not firm, add another egg, without beating the white, which makes the quenelles puff and hollow within. This is a farce of general use.

5235. *Quenelles of Fowls.*—Take the fillets of young fowls, and, after removing all the sinews, cut the meat into dice, and pound it till it can be rubbed through a sieve; then with eggs unite it to some of the panada and flavouring ingredients, pound all together, and try a small ball in hot water; if it is not hard and firm enough, add more egg. When intended for ragouts, *quenelles* must be made very firm and hard. When the quenelles are used small, the farce may be more delicately and lightly made. Do not omit, among the seasoning ingredients, salt and pepper.

5236. *Quenelles of Fish.*—Take either the flesh of whitings, salmon, pike, &c., without skin or bones, pound it, and force it through a sieve or colander, beat an equal quantity of panada, and pass that also through the sieve; of butter, the same quantity must be beaten with the two other portions of the quenelles, the fish and panada; to these add salt, spicery, and pepper, a table-spoonful of fine herbs pounded and cooked in butter; incorporate these ingredients with eggs; try some in boiling water, and finish with white of egg, if the quenelles require firmness

Subsect. 4.—*Farced-meat Balls for Pies.*

5237. There are a variety of meat pies into which these farced-meat balls are introduced, as pigeon, chicken, ham and veal, game, &c. Beat in a mortar equal parts of fat bacon and lean veal to a smooth paste; season them, and add any herbs you may choose, as parsley, eschalot, button mushrooms, green onions, a little lemon peel chopped fine; mix this with double the quantity of the prepared panada; incorporate these well together with yolk and white of egg beaten up together, and, with a little flour, roll them into balls. It is always proper to poach them for a minute or two in salt and water, to make them preserve their shape, and to prevent them from sticking together.

5238. *Egg Balls.*—Beat in a mortar the yolks of four boiled eggs, with some pepper and salt, and a tea-spoonful of flour; mix them with a raw egg, yolk and white beat together. Roll them into balls, smaller than you desire when produced at table, as they swell in boiling. Poach them for two or three minutes. These are plain; but if you prefer it, chopped vegetables may be added.

5239. *Curry Balls.*—These are composed of the plain egg balls, mixed with some of the prepared panada, with the addition of curry powder, well incorporated together.

5240. *Sausage Balls.*—Ordinary sausage meat is to be beaten smooth in the mortar, and incorporated with yolk and white of egg.

5241. *Balls for Mock Turtle Soup.*—Pound some veal in a marble mortar; rub it through a sieve with as much of the udder as you have of veal, or about a third quantity of butter. Moisten some bread crumbs in milk, and add some chopped parsley and eschalot, rubbing the whole together till it form a stiff paste. When cold, pound and mix all together with the yolks of three eggs boiled hard; season it with salt, pepper, and curry powder or Cayenne; add to it the yolk of two raw eggs, rub it well together, and make small balls. Ten minutes before your soup is ready to serve, put them in.

Sect. V.—Gravies, Sauces, and Purées.

Subsect. 1.—*Gravies.*

5242. *Jus de Bœuf.*—See "Beef Gravy," "English Cooking."

5243. *Blond de Veau.*—See "Veal Gravy."

5244. *White and Brown Roux.*—See "English Cooking."

5245. *Coulis.*—Make the coulis in the same manner as veal gravy, with slices of ham and veal, &c. When the glaze made of the gravy is of a fine colour, moisten it and let it stew. Season it with parsley, green onions, and mushrooms. Mix some brown roux with it; but do not make it too thick, or the fat will not be readily removed, and a fat gravy or sauce is never agreeable. After adding the roux, let it simmer gently for an hour. Skim off the fat, and strain it.

Coulis of fish, game, or poultry is made in the same manner.

Subsect. 2.—*Sauces.*

5246. *Sauce Robert, for Roast Pork or Goose.*—Cut into dice a few onions, and fry them lightly in butter. When they begin to brown, add a dessert-spoonful of flour, a ladleful of stock, the same of vinegar, some salt and pepper. Pulp the whole through a sieve, and reduce it to a proper thickness. When ready for table, have two spoonfuls of *made* mustard. In addition to these ingredients, Dr. Kitchener recommends two dessert-spoonfuls of mushroom catsup, or the same quantity of port wine.

5247. *Sauce Espagnole.*—Put into a stew-pan slices of ham and veal; moisten and warm them. Let the glaze produced go to the bottom. When turning of a good red colour, add a little consommé to detach the glaze from the stew-pan. Pour in some coulis; boil the whole half an hour; skim off the fat, and strain it. In all sauces, remember to add mushrooms, a bunch of parsley, and green onions.

5248. *Espagnole of Game.*—This is prepared in the same way, trimmings of game being added to the veal and ham.

5249. *Sauce Tournée.*—Moisten some white roux with veal gravy, into which put some mushrooms, parsley, and green onions; let them gently stew by the side of the fire until the vegetables have given out their goodness; then skim off the fat, and strain it. If this sauce be farther reduced by evaporation, it forms, by the addition of some cream well mixed with it, the *sauce velouté.*

5250. *Poivrade Sauce.*—Put into a stew-pan a piece of butter the size of an egg, and some slices of carrot, turnip, and onion, two eschalots, two cloves, a bay leaf, thyme, and basil; set the pan on the fire, and stir the contents till they become finely browned; shake in some flour; add a glass of red wine, a glass of water, a spoonful of vinegar, and pepper and salt; boil half an hour. Skim and strain it.

5251. *Sauce à l'Allemande.*—Sauce à l'Allemande is sauce tournée into which a liaison of two yolks of eggs is introduced. This sauce is for all the following sauces or ragouts, blanquettes of all descriptions, of veal, fowl, game, or palates.

5252. *White Italian Sauce.*—After boiling some mushrooms, throw them into water and lemon juice to keep them white. Put into a stew-pan two thirds of sauce tournée and one of consommé, two spoonfuls of mushrooms chopped finely, and of which the colour has been preserved; add half a spoonful of finely-minced eschalots. Reduce the same; season it, and serve it.

5253. *Brown Italian Sauce.*—From the assiette (a dish with four compartments, in which chopped seasonings are put ready for use) take two spoonfuls of eschalots, one of parsley, and two spoonfuls of chopped mushrooms; put them into a stew-pan with two thirds of Espagnole sauce and one of consommé: some add white wine; but this sauce may be made very well without it. Put in very little salt or pepper, nor allow the sauce to thicken. Brown sauces should not be as thick as white. When done enough, change the stew-pan, and put it in a bain marie. Skim it with care, so as not to remove the parsley with the fat.

5254. *Béchamelle Sauce.*—Reduce, over a good fire, some sauce tournée; moisten it with *chicken broth* or consommé, constantly stirring it to prevent its being burned. When of a proper consistence, add two glasses of boiling cream, stirring it well in. Strain it, and serve.

5255. *Sauce aux Truffes.*—Truffles, if good, ought to resist the pressure of the hand; if soft and gluey, and having the smell of cheese, they are not good. Take two pounds; pick, and throw them into water: such as swim are not as good as those that sink to the bottom. Break them, and throw them again into fresh water—not into hot, or they will lose flavour; with a knife remove all specks or bits of wood upon which they had been stuck by the venders; wash them again until the water is no longer turbid; peel, and cut them in slices or dice; put them in a stew-pan, with a piece of butter, over a slow fire; let them sweat, and moisten them with half a glass of wine and two spoonfuls of reduced Espagnole; simmer them gently over a slow fire, adding more butter; skim it, and stir it well; put no lemon juice, as that would take off the softness of the sauce.

5256. *Sauce Piquante.*—Put two or three spoonfuls of Espagnole or coulis into a stew-pan, with a spoonful of white vinegar, a bay leaf, a clove of garlic, a little thyme, a clove, some broth, and a little salt; boil it half an hour; skim it, and pass it through the tamis.

5257. *Sauce à la Reine for Boiled Chickens.*—Beat in a mortar the white part of a dressed fowl with an ounce and a half of blanched almonds till they form a smooth paste; mix with it a small French roll, moistened with half a pint of boiling veal stock or broth, and the yolks of two boiled eggs; stir in sufficient flour to render it of a proper consistence; and, when seasoned, pour it boiling hot over the chickens.

5258. *Maître d'Hotel Sauce.*—Work over a stove a lump of fresh butter in four spoonfuls of Allemande; chop parsley, and, with the juice of a lemon, some pepper and salt, put into the sauce. Let this sauce be made thick, in general. It is easier to thin than to thicken a sauce after it is once made. The flavour is often injured by the necessary addition of flour, butter, &c.

5259. *Tomato Sauce.*—Take a dozen of very ripe tomatoes; cut off the stalks and take out the seeds; squeeze out the juice from the fruit and put it into a stew-pan with half an ounce of butter, a bay leaf, and a sprig of thyme; stir all together over a moderate fire until a purée is formed; add to it a spoonful of *top pot* (see Terms), and rub it through the tamis; return it to the stew-pan, and add two spoonfuls of Espagnole sauce. Make it of the consistence of a thin gravy; season with salt and Cayenne.

5260. *Glaze.*—Glaze is an ornament for the surface of some made dishes: it may be formed of the remains of any liquor in which meat, poultry, or game has been cooked. Let this liquor be strained till perfectly clear, and put over a brisk fire till reduced to the consistency of jelly; when it begins to stick to the spoon, remove it to a smaller stew-pan, and set it in a bain marie. It will keep some little time, and becomes black and bitter when no longer fit for use. Remember to warm it always in the bain marie, that it may not get too brown or deeply coloured.

Subsect. 3.—*Purées.*

5261. *Soubise, or Purée of Onions.*—Take a dozen white onions, peel, wash, and cut them in halves. Mince and blanch them. Put them into a closely-covered stew-pan, with a small bit of ham, a little mace, half a bay leaf, and simmer them for one hour. Rub them through the tamis, and add four spoonfuls of béchamelle; keep it hot, but without boiling.

5262. *Purée of Celery.*—Wash and string several heads of celery; blanch them, and strain away the water when it becomes cold. Put the celery into a stew-pan with a little consommé and sugar. Stew it for an hour and a half, and reduce till there be no kind of moisture. Mix four spoonfuls of béchamelle or velouté, strain the whole through a tamis, and put it into the bain marie. When ready to serve, add boiling cream to thicken it and improve the colour.

A variety of purées may be made of vegetables; also of fish and game.

Purée of potatoes is merely well-mashed potatoes moistened with good broth until the whole is not much thicker than a cream. Instead of broth, cream is sometimes used as the moistening ingredient.

Sect. VI.—Entremets.

Subsect. 1.—*Omelettes.*

5263. Break six eggs into a basin, at the bottom of which some salt dissolved in a tea-spoonful of water and a little pepper had been previously put. Keep back three of the whites. Omelettes are sometimes tough, from having too much white of egg in them, as well as from being too thin. Beat the eggs thoroughly, and pour them into a frying-pan with a small quantity of butter. Keep turning the pan continually, but never let it be too near the fire. When the sides begin to harden, roll the omelette up before the middle part, which should be kept soft, gets too much fire. Roll it equally with the knife before it is dished; and, in turning it out of the frying-pan, take care not to soil the dish.

The general principle of making an omelette being thoroughly comprehended, various additions may be made; thus, you may form an omelette of ham, by mincing some that has been boiled, either with or without herbs. It may likewise be composed of cold fowl minced or beaten in the mortar, properly seasoned, and, to render it more relishing, an anchovy may be pounded with it. A very elegant omelette may be compounded by adding a quantity of scraped Parmesan cheese to the batter. The kidney fat of veal may likewise be employed when finely chopped, and heated in some strong consommé; this may be put into the middle part of the omelette before it is rolled.

5264. *Omelette of Herbs.*—To the mixture of eggs already described add some chopped parsley, and a little eschalot minced very fine, and proceed as above directed. In some instances, sorrel scalded and chopped may be used as a variety.

5265. *Omelette Soufflé.*—This is a raised omelette, and is made by beating the yolks of six eggs with a little grated lemon peel, salt, and sugar. The whites are to be separately beaten till they become an entire froth. These are then to be slightly mixed together; and when the margin has become solid, so as to contain the central part, it is to be put into the oven, that it may rise, which it will do to a considerable height, if sufficient heat be applied to the upper part. If you choose, it may be glazed.

5266. *Omelette Soufflé au Gateau au Riz.*—Boil a little rice in milk and water till quite soft. When cool, put in as much orange-flower water and sugar as may please the taste. Whip the yolks of eight eggs, and mix them with the rice. Then whip to a complete froth the whites, and, just before it is to be baked, add them, and whip all together. Put it into a tin soufflé-dish, just large enough, and then into a very brisk oven, allowing twenty minutes for baking it. The top surface alone should be browned; the rest should be as white and as light as possible.

5267. *Salamandered Eggs.*—When you desire to have eggs served together, first butter the inside of the dish, and place the eggs regularly in it, sprinkling over them some salt and pepper. Cover the eggs with pieces of butter. Place the dish over a moderate heat, and use a salamander at the top till the whites become solid.

5268. *Eggs in the Italian Method.*—Warm some flour and butter in the stew-pan till they are sufficiently incorporated. Moisten with some boiling milk, and season with pepper and salt; next put in about three ounces of fresh butter and a couple of teaspoonfuls of chopped parsley; work these well together. Have ready eight eggs boiled hard; slice them, and put them into the sauce. Serve them up hot, sprinkled with some additional salt and lemon juice.

5269. *Œufs à la Neige.*—Boil a quart of new milk with a large spoonful of orange-flower water and a quarter of a pound of sugar, without stirring. Beat the white of eight eggs to a complete froth. When the milk boils, with a very large silver spoon take as much of the froth as it will hold, and put it at the top of the boiling milk, and let it remain till a little hardened, pouring gently over it with the spoon some of the milk which it imbibes. When cooked sufficiently *it should boil.* Take it gently off the milk in large spoonfuls, and put it in your dishes; it will be enough for two; and after having cooked the white of the froth in this way, which takes nearly half an hour, make a custard of the milk which remains and the yolks, taking care to drain all the milk from the glass dishes. Pour the custard all over the froths while it is hot.

Subsect. 2.—*Vegetable Entremêts.*

5270. *Potato à la Maître d'Hotel.*—Boil in salt and water some unpeeled potatoes. When done, let them cool, and cut them into the shape and size of large corks. Warm them up in sauce *à la maître d'hotel.* (See "Sauces.") When there is no sauce at hand, supply its place with melted butter, with some finely-chopped parsley, pepper, salt, juice of lemon, and a little glaze. Mix it well before putting the potatoes into it; boil it up carefully, lest the potatoes should break. Serve them.

5271. *Casserole of Potatoes.*—Boil potatoes well. Mix butter, cream, and salt together, with which make the potatoes of a thick mash. Serve it, leaving in its centre a space for a ragout, macaroni, or fricassée. Before the ragout is added, the casserole must be baked of a fine brown.

5272. *Turnips, with Sauce Blanche.*—Turnips are admitted as entremêts in the winter only, during the scarcity of other vegetables. Cut them into shapes of pears or balls; boil them in salt and water and butter; drain them, and serve with sauce blanche.

5273. *Turnips, glazed.*—Cut some turnips into shapes, and stew them in broth with a little sugar. When done, reduce the broth to a glaze, andglaze each turnip. With a spoonful of Espagnole dissolve the glaze remaining in the stew-pan, and work into the same a small bit of butter the size of a walnut. Season the same, and pour it over the turnips.

5274. *Carrots à d'Orleans.*—Take a few young carrots and cut them in slices about the eighth of an inch thick. Blanch and drain them. Put them into a stew-pan with a lump of sugar and some broth. Let them boil over a large fire. Reduce the broth to glaze, and add butter and salt. When served, the butter must adhere to the carrots.

5275. *Spinach au Consommé.*—Take care that in the spinach neither stalks nor weeds are left; it must be washed several times in plenty of cold water. Some people put it into a sauce-pan without more water than that which the leaves retain after washing; others prefer its being boiled in salt and water; a few boils will be sufficient; then put it, without loss of time, into a colander to drain, and afterward into cold water, to preserve the colour; when quite cold, press the water well out of it; spread it on a wooden trencher with the knife, to see if any weed or stalk remains in it; chop it very fine, put some butter into a stew-pan, and lay the spinach over it. Dry it over a gentle fire, adding, by degrees, a spoonful of flour; moisten it with consommé, and then stew it briskly, that it may not turn yellow; make it rich with a small piece of glaze. Some people add nutmeg; a little may be grated in, and it may be dished with either fricandeaux of veal or mutton. If to be served as an entrée under ham or tongue, mix with it some sauce Espagnole.

5276. *Spinach, with Cream.*—Blanch and prepare as above, using cream instead of consommé. Boil the cream before pouring it over the spinach, lest it should curdle; add butter, salt, and a little sugar and nutmeg. Serve it with fried toasts of bread, or flourets of puff paste freshly made.

5277. *Cauliflower à la Sauce Blanche.*—Tear off the green leaves and open the cauliflower; remove all snails and insects which may be lodged near the centre; leave the cauliflower in cold water for an hour; next put it into boiling water with salt and butter. It is soon done, and will break to pieces if too long boiled; drain it and dish it, pouring sauce blanche over it.

5278. *Asparagus au Jus.*—Clean, cut, scrape, and throw into water some asparagus sprouts; tie them up in bundles; cut them into equal lengths, and put them into boiling salt and water; boil for a quarter of an hour; drain them and dress them across one another, or in bundles. Serve them in a dish containing sauce half Espagnole and half butter, warmed together.

5279. *Les Petites Pointes d'Asperge.*—Have small asparagus sprouts cleaned and cut into pieces the size of small pease; blanch them in boiling water with salt; when tender, drain and put them into cold water; dry them in a clean towel, and put them into a stew-pan with a small bit of butter, some parsley, and green onions; let these simmer quickly, adding a lump of sugar, a little salt, and two or three spoonfuls of sauce fournée; let this boil, to keep the asparagus green; thicken with two or more eggs, according to the quantity, two eggs to a pint of asparagus pease, and so in proportion. This dish, when well prepared, has precisely the flavour of pease.

5280. *Windsor Beans.*—Take a quartern of small Windsor beans; boil them in weak salt and water; into a little veloute throw half a quarter of a pound of fresh butter, some chopped parsley, and winter savoury; after draining the beans, toss them in this sauce, and serve under ham or bacon.

5281. *Windsor Beans à la Poulette.*—The beans must be young and fresh gathered; boil them in salt water;

drain them, and stew them in *sauce tournée* (see "Sauce"), with some parsley, green onions, a little chopped savoury, and a lump of sugar. When the beans are reduced, throw in a thickening of the yolks of two eggs and cream. Send them up in a short sauce, and properly seasoned.

5282. *Pease.*—Take two quarts of green pease, put them into a pan with cold water and three ounces of butter; handle them in the water, so that the butter may be equally distributed over their surface, in order that they may adhere together; drain off the water, take out the pease by handfuls, and put them into a colander. In this state, equally smeared with butter, stew them over a moderate fire, with a bunch of parsley and some green onions; dust a little flour over them, and stir them carefully; next pour over the pease sufficient boiling water to cover them, but not more; let this boil fast, to evaporate the water quickly; when it is dissipated, put in a lump of sugar, moistened, that it may be more speedily dissolved, and a little salt; have ready mixed two ounces of butter with some flour, which stir into the pease, and let it be so equally distributed among them that none remain at the bottom of the pan.

5283. *Green Pease à la Paysanne.*—Prepare the pease as in the preceding recipe; take a few cabbage and cos lettuces, a handful of parsley, and a few green onions; wash them, and, instead of cutting, break them; drain them from the water, and put them with the pease over a very slow fire. No other moisture will be required than the butter; stir the contents of the stew-pan repeatedly, that they may not burn. When done, add pepper and salt, but no thickening.

5284. *French Beans à la Poulette.*—Boil them in salt and water to preserve their colour; take some sauce tournée, reduce and thicken with the yolks of two eggs, to which add finely-chopped parsley; work into the thickening a lump of fresh butter, pepper, salt, and the juice of half a lemon; drain the beans well, and dish them lightly, that the sauce, which must cover them, may also penetrate to the bottom of the dish.

5285. *Artichokes in White Sauce.*—Pare the bottoms, and take off the points of the leaves of three or four artichokes; put them into a large pot of boiling salt and water; after boiling them well, throw them into fresh water; take away the small leaves with care, that the choke may be entirely removed; replace the leaves, and put them again into hot water. Drain, and serve them with sauce as before.

5286. *Celery, with Sauce Blanche.*—Cut into lengths twelve heads of celery; stew them in a little water, butter, and salt. When done, drain them, and serve with sauce blanche. If the celery is somewhat green, blanch it with boiling water, putting it into a blanc as for celery sauce.

SUBSECT. 3.—*Entremêts of Sweet Dishes.*

5287. *To prepare the Rice for Curry.*—The object to be attained in this preparation is to bring the rice to table sufficiently done and swollen, without sticking together. Take half a pound of rice picked clean and washed; throw it, a little at a time, into a large quantity of boiling water, and let it simmer till three parts done; take it out cautiously, and place it on a hair sieve to drain, and pour plenty of cold water on it, that all the vegetable glutinous matter may be washed off. Put it into a stew-pan, with a cloth at bottom and another at top, and set the stew-pan in a gentle heat (that of an oven is best), that the moisture may be exhaled from it, and imbibed by the upper cloth.

5288. *Casserole of Rice.*—Take a pound and a half of Carolina rice, wash it in warm water, and put it into an open stew-pan; cover it with stock in this proportion: if the rice lie one inch deep in the pans, let the stock rise two inches above it, and so on; boil and skim the surface as the impurities arise, then withdraw it from the fire and set to simmer only; in twenty minutes stir it, and let it simmer on twenty minutes longer; stir it again, and, if the rice be perfectly soft, take it off; if not, add more stock, and continue the simmering until it is done sufficiently. Drain away the fat, by setting the sauce-pan aslant, and before the rice is cold, work it well with a spoon or spatula into a fine, smooth paste; it can hardly be worked too much; every grain of rice should undergo the pressure, and more stock should be worked in if it appear too dry. Form your casserole of this paste, by laying it in a heap four or five inches high and about seven in diameter: work it with the hand as if for a raised pie, or pat it on a mould, and ornament it on the outside with cut carrots, not pressed into the rice, but standing out from it like the bas-relief of ornamented vases. Then mask the whole surface with clarified butter, and place it in a hot oven for an hour and a half; when of a fine yellow colour take it out, remove the top of the casserole, and clear away the rice that does not adhere to the crust, which should be as clear as possible. Mix some béchamelle or Espagnole with the rice, and put it again into the casserole with such ragouts as may have been prepared for it. Glaze the outer ornaments, and serve it. Water, butter, and salt are often used in preparing the rice instead of stock, as preserving better its colour. A casserole may contain either white or brown ragouts, blanquettes, minces, or fricassées of poultry, scollops of fish, macaroni, &c.

5289. *Turban de Riz.*—Wash a quarter of a pound of rice in two or three waters. Take a quart of good cream, boiling it to see that it will not curdle; infuse some lemon peel in the cream for a quarter of an hour; take it out, and put in the rice; lay it on a very slow fire till the rice bursts, and, when swollen, add a very little salt and some sugar; when done enough, add the yolks, well beaten, of eight eggs. Next beat the whites, and add them to the other ingredients, mixing them slowly. Then have some apples ready peeled and quartered; put a gallipot in the centre of the dish, to form a vacancy for some vanilla cream afterward to be added. Lay the rice round the gallipot with a spoon, levelling it with the back of the spoon. Next place the apples round the rice till they reach the summit. Next put it in the oven, but leave it there only until the sirup of the apples is dried up; decorate the dish with sweetmeats of greengage, apricots, or cherries, and, when ready to serve, remove the gallipot, and fill the space with vanilla cream. (See "Confectionery," for vanilla cream.)

5290. *Macaroni.*—This is prepared in various ways: first, by simply simmering the macaroni in water in which some pepper and allspice tied up in muslin have been previously boiled together, with a piece of butter and some salt. When nearly done, pour off the liquor, and let it steam by the fire-side. It is usually, when prepared in this manner, kept hot in a silver sauce-pan, and served at table when wanted.

5291. *Macaroni another Way.*—Boil four ounces of macaroni till tender in veal broth; then drain the broth from it, and add two table-spoonfuls of cream, an ounce of fresh butter, and two table-spoonfuls of grated Parmesan cheese, with some salt and pepper. Mix these well together over the fire for a few minutes; put it into a dish made hot to receive it; strew equally over it some grated Parmesan cheese, and apply the salamander.

SUBSECT. 4.—*Entremêts of French Pastry.*

5292. *French Puff Paste.*—For this a pound of sifted flour will require a pound of butter. If the weather be warm, the butter must be hardened by standing for some time on an ice-tub, or by putting it into cold salt and water. When hardened, half of it is at first rubbed in the flour, which is worked into a paste moistened by the *yolk* of an egg, and a tea-spoonful of the white (yolk and white must be previously and separately beaten). If more moisture be required to make a smooth paste, water must be employed, but in the least possible degree. Roll out the paste, and at three separate times roll out and lay on the butter in patches.

5293. *Paste for stringing Tartlets.*—This consists in simply adding flour and more water to a puff paste, and when well kneaded together it will become sufficiently ductile to be drawn out and twisted at pleasure.

5294. *Crisp Paste.*—This kind is usually preferred for tarts: it is stiffer than puff paste. It consists of half a pound of butter to a pound of flour, a quarter of a pound of loaf-sugar sifted, and four eggs well beaten; this is formed into pastry with cold water, and rolled out.

5295. *French Tourte.*—Cover a flat dish, called a tourte-pan, with thin pastry, and edge the rim with a layer of puff paste. Fill the centre with any kind of preserve or sweetmeat, and ornament it with leaves of puff paste; bake it, and serve it cold.

5296. *Croquante of Paste.*—Make the pastry for croquantes of half a pound of fine flour and a quarter of a pound of sifted loaf-sugar; mix these well together with yolks of beaten eggs until of sufficient stiffness. Roll out the paste about the eight of an inch thick, rub over a plain mould with fresh butter, and lay the paste on the outside, of equal thickness over each part. Pare it neatly round the rim, and ornament it with stars, leaves, or sprigs of paste, as fancy may suggest. Let these lie till dry; then in a slack oven bake the pastry for a few minutes of a light colour. Remove the mould, and put the croquante over a tourte or small dish of pastry.

5297. *Vol au Vent.*—These are made of puff paste, which is to have additional folding and rolling; by this process it will become very light. Brush them over with yolk of egg after they are in the moulds, and let each contain a piece of crumb of bread, which take out when baked, and fill the vacancy with savoury composition or preserved fruit. (See "Puff Paste," "English Cookery.") When vol aux vents are used for entrées, they must be filled with ragouts either of meat or fish; if for entremêts, with vegetables, sweetmeats, or soufflés.

5298. *Pâte d'Amandes.*—Blanch and beat to a smooth paste a pound of sweet almonds with a quarter of a pound of butter. While pounding them, add from time to time a drop of water and a drop of white of egg alternately, which last may be dropped through a small puncture made at the end of an egg. Add also a little lemon juice to whiten the almonds. When reduced to a paste, put in three quarters of a pound of sifted sugar; take the paste out of the mortar, and put it into a tin sauce-pan, or a sweetmeat-pan of bell-metal, over a slow fire; stir it and stir it till it no longer sticks to the spoon. Strew the table with sifted sugar, and roll out the paste on it; wrap it in white paper, and keep it for use.

5299. *Tartelettes à la Chantilly.*—Take almond paste, strew the table with fine sifted sugar, and roll it out, using sugar instead of flour. The paste for the bottom of tartlets must be no thicker than a sheet of paper. Cut them the proper size for *petit pâtés.* Make the bands of the same paste, three quarters of an inch broad and high. Wet the edges of the tartlets with white of egg a little beaten, and fix on the bands in the form of goblets, and so neatly as not to show the joining. Put them on white paper, and dry them in an airy place. Afterward put them only at the mouth of the oven, to dry more and yet to receive no colour; fill them with whipped cream, or, in summer, with strawberries.

5300. *Mirletons de Rouen.*—Roll out half a pound of puff paste as thin as a shilling; cut it in forms, and put it into little pans. Work together in a basin a quarter of a pound of fine sugar with an egg. Add to this a little melted butter, some orange-flower water, and another egg worked in; fill the moulds, sift sugar on the surface, and bake them slowly. Place them in a pyramidal form on a dish, and serve as a small entremêt.

5301. *Ramequins*.—Ramequins are considered as entremêts of pastry. There are two ways of making them: the first consists in rolling out a quantity of puff paste, and sprinkling over it some grated Parmesan cheese, then in folding it up and rolling it out again, and again sprinkling it over with the cheese. These processe must be repeated three or four times; the paste is then cut into square or oblong pieces, brushed over with beaten yolk of egg, and baked.

5302. *Ramequins* (second way).—For ramequins there is also another receipt. Three ounces of fresh butter is put into a stew-pan with a table-spoonful of water; when melted, three eggs must be added, and worked well into the butter. An anchovy beaten to a paste, with a little pepper, is next added, and all the ingredients are moistened with two table-spoonfuls of cream, to which is added an equal quantity of Parmesan cheese finely grated; these must be stirred well together; and some paper moulds being in readiness, the mixture is poured in, and baked for a few minutes only.

SUBSECT. 5.—*Entremêts of Fruit.*

5303. *Stewed Pears.* — Scald some pears, and when soft take them out of the hot water and put them into cold: pare, core, and quarter them; boil them in sirup made of loaf-sugar, and to every pound of fruit put a pint of sirup; cover them close while boiling; and, by way of giving them a fine colour, cochineal, tied in a muslin bag, may be put in, to be removed as soon as the colour is obtained. The juice of three lemons and a little of the rind are then put into the sirup and boiled up. A quart of water and three pounds of sugar are the proportions for the sirup.

5304. *Stewed Apples (with custard).*—Pare, core, and cut into slices some apples, steep them with lemon juice, peel, and some loaf-sugar. Put them, when done and cold, into a pie-dish; cover them over with an unboiled custard, and bake till the custard is set. They may be served either hot or cold.

5305. *Pommes à la Polonaise.*—Core with a scoop, so as not to break them, a dozen small rennet apples, afterward pare and cut them in slices. Cover a dish (not a very deep one) with apricot marmalade and the slices of apple, alternately, forming the layers as much as possible into a dome. Glaze the last layer with sifted loaf sugar, put it into an oven for half an hour, and carefully wipe the edges of the dish when it is done.

SUBSECT. 6.—*Entremêts of Cream.*

5306. *Italian Cheese, à l'Orange ou au Citron.*—Take a quart of cream, a pint of white wine, a glass of brandy, and six ounces of lump sugar. To these add the juice of two lemons, and the rind of one obtained by rubbing it with lump sugar. Line a small hair sieve with muslin, sufficient of which should fall over the sides to allow of the cream being afterward gently lifted out of the sieve. With a whisk whip the cream until it becomes thick and almost solid, fill the sieve with it, and then set it on a basin or jar, that the whey may drain out of it. When firm, turn it on the dish on which it is to be sent to table. Fill up the sieve, in the first instance, as high as possible, to allow for the loss of the whey; also, remove carefully lemon or orange peel before the cheese sets.

5307. *Fromage Bavarois.*—Boil half a pint of cream, and when cool add to it the beaten yolks of nine eggs, a little salt, half a pound of sifted sugar, and some crisped orange flowers. Let these simmer gently over a slow fire, stirring them constantly until they thicken, but not allowing the liquid to boil. Strain the whole through a silken sieve, and have in readiness an ounce of clarified isinglass to add to the cream, with a Chantilly cheese; incorporate the whole together, and pour it into a mould. Ice it for three hours; when to be served, dip the mould into hot water as hastily as possible, and turn out the contents on the dish it is to be sent in to table.

5308. *Fromage d'Abricots.*—In summer take twelve apricots, peel, stone, and pound them with a little sugar; rub them through the tamis, and to this juice add an ounce of clarified isinglass; whip a pint of thick cream, and add it to the apricots: taste if the whole be sweet enough; and, when sufficiently sugared, whip the whole over ice until the isinglass is dissolved and blended with the fruit and cream; put it into a mould, keeping ice and salt all round it. If the mixture be not stirred while it is becoming consistent by freezing, the apricots will sink to the bottom of the mould, and the fromage will be spoiled, one part yellow and tough.

In winter this fromage may be made of apricot marmalade, rubbed through a hair sieve to dissolve the isinglass; a pint of thick cream is then whipped and mixed over the ice with the marmalade; the whole is then put into a mould, and when it is becoming consistent may be left on the ice-tub till it is to be served.

Fromages of *strawberries, raspberries, pineapple,* may be made in the same way.

Fromage de Pêche.—Infuse in a sirup the peaches, and, when tender, drain them and blanch the kernels; pound these extremely fine, and rub them with the fruit through a sieve, mix it with some whipped cream, and then put it into moulds, and proceed with it, over the ice-tub, as with apricot fromage.

SUBSECT. 7.—*Entremêts of Jelly.*

5309. *Italian Jelly.*—Make a calf's foot jelly (see "Calf's Foot Jelly," E. Cookery), and when clear half fill a mould; take some Italian cheese out of a plain mould, and cut it into small rounds with the round cutter; lay these pieces of cheese in circles round the jelly in the mould, and, when neatly arranged, pour on them some more calf's foot jelly. Let it set, and then gently add more and more of the jelly until the mould is filled. In summer set it in the ice-pail, to fix it more firmly; in the winter a cool place will be sufficient. Hold the mould for an instant in hot water before the jelly is turned out.

5310. *Jeleé de Fraises Framboises.*—Take a pint of fresh-gathered raspberries, and, picking them carefully, set them over the fire with a small quantity of water; when hot, strain them through a tamis, and clear them by passing them through a jelly-bag; add to them an ounce of dissolved isinglass and half a pound of sifted sugar; warm all together, but stirring them constantly; strain and put the jelly into a mould, set the mould in a pail of ice for three hours; when wanted, dip the bottom of the mould quickly into boiling water, and turn out.

Strawberry, orange, and lemon jelly is prepared by the same process.

For fruit jellies isinglass is to be preferred to calf's foot stock, as it is always clear and free from flavour.

5311. *Maderia Wine Jelly.*—Make a calf's foot jelly, and when nearly clarified pour in a bottle of Madeira wine and some brandy (a quarter of a pint). The jelly, in clarifying, deprives both the wine and the brandy of much of their strength. It is a jelly that may be kept for several days; hence, when any is sent from table, it should be melted again and put into a fresh mould, to serve another day. This jelly is often ornamented by a thickened jelly, prepared by breaking four eggs into a stew-pan, and beating them up with a few table-spoonfuls of the Madeira jelly and a little sifted sugar; the stew-pan is then put over the fire; the contents are stirred together until they thicken; they are then passed through a sieve into a dish, which is placed in an ice-pail and kept there for three hours; when it is mingled with transparent jelly, as described in the receipts for Italian jelly, it should also be decorated with Chantilly cheese.

BOOK XV.

CONFECTIONERY FOR DESSERTS, ROUTS, AND BALLS.

5312. *Confectionery being in the present day a business of itself,* is not now uniformly practised as a domestic art; in truth, no domestic skill can compete with confectioners by trade, whether the success of their productions, or the expense attending them, be considered. Confectionery processes cannot be carried on without the aid of apparatus and considerable experience, nor without the employment of many efficient hands besides those of the master confectioner. On some occasions ornamental confectionery may be required, and in such cases the purchase of them from the confectioner secures the best of the kind, and at the least expenditure of trouble and money. Acting upon such reasoning, all elaborate receipts for ornamental confectionery are here omitted. The receipts here given will be confined to those by which may be made *cakes* and *biscuits, ices* and *compôtes*, together with the dry and liquid confects which may be wanted at desserts, or at routs and balls. For the application of *sugar* in preserves of fruits, marmalades, and jellies, the reader is referred to Book X., Chap. IV., Sect. VII., "Preservation of Food." Receipts for *creams*, and for *jellies* used as entremêts, will be found under "French Cooking."

CHAPTER I.

CAKES AND BISCUITS.

SUBSECT. 1.—*Cakes.*

5313. *The oven, when cakes are to be baked*, must be "quick," as the cook terms it, when slow, cakes will not rise properly, hence they turn out what is termed "heavy." To find out when baked enough, half open the oven-door and plunge a bright blade of a knife into the centre of the cake; if done enough, the knife will come out as clear as it went in; if not done enough, some of the cake will adhere to it. The door of the oven must in that case be immediately closed again, to prevent the cakes from falling.

Currants required for a cake must be previously cleaned and dried before the fire; if they are put into a cake *wet*, it will not rise properly.

Eggs to be added to cakes must be well beaten previously, the yolks and whites separately.

Lemon peel, thinly pared, should be pounded to a paste, with a little sifted sugar, and mixed with either wine or milk, that it may be more easily mingled with the other ingredients.

A little yeast, beaten with sugar and the yolk of an egg, makes a cake much lighter than any quantity of eggs or butter can do.

All the ingredients of a cake, when put together, must be beaten for a considerable time. Some confectioners cause this to be done for the chief part of an hour, as the lightness of a cake depends principally upon the ingredients being very thoroughly intermingled.

5314. *Rich Plum Cake.*—The ingredients are, 1½ lb. of flour, 1 lb. of butter, 1 lb. of sugar, ½ lb. of candied citron and orange peel, 2 oz. of sweet almonds, ½ oz. of allspice, ½ oz. of cinnamon, 10 eggs, and one glass of brandy.

To mix the ingredients, beat the butter to a cream; add the sugar to it; stir them together for a long time; add the allspice and pounded cinnamon; work in the yolks of the eggs two at a time; beat the whites till they are highly frothed; work in the whites gradually, keeping the paste warm, or it may become heavy. Cut into stripes the citron and orange peel; mix them with the currants (previously well washed and dried before the fire), and also with the almonds; stir in by degrees the sifted flour, then the brandy; with a whisk beat the whole together for a considerable time; put the cake into a tin hoop, and bake it for three hours. Let there be several sheets of paper both under the cake and on the top of it.

Sugar Ice for Plum Cake.—When the cake is almost cold, beat and sift eight ounces of fine loaf-sugar, and put it into the mortar with four spoonfuls of rose-water, the juice of a lemon, and the whites of two eggs beaten to a froth and strained. Whisk these ingredients well together, and with a paste-brush cover the cake with it. Set the cake in a cool oven to dry the iceing, but not to discolour it; an hour will harden it. When cold, let the cake be covered over with thin white paper, to preserve the delicacy of the iceing.

5315. *Common Plum Cake.*—The ingredients are, 2 lbs. of flour, 1 lb. of butter, ½ lb. of currants, ¼ lb. of sugar, 1 oz. of citron and lemon peel, ¼ oz. of nutmeg or ginger, 1 table-spoonful of good yeast, and 3 eggs. Set the flour as if for bread, with the yeast, eggs (well beaten), and some sugar, mixed well together, and poured in the middle. Let these ingredients stand before the fire until the yeast has worked its way into the flour; add the butter, beaten to a cream, the currants, sweetmeats, &c., and mix all thoroughly together. Put the whole into a tin band, and set it on paper before the fire to rise; put it, when risen, into the oven, and bake it for an hour and a half, trying it with the knife before it is taken completely out of the oven.

5316. *A rich Seed Cake.*—The ingredients are, 1 lb. of flour, 1 lb. of butter, 1 lb. of sifted sugar, 8 eggs, ¼ oz. of powdered cinnamon and nutmeg, 1 oz. of caraway seeds, and 1 glass of sherry. Warm the flour before the fire; beat the butter to a cream, mixing the sugar, pounded and sifted, with it, before any of the other ingredients, but not until the butter is brought to a fine cream. Beat separately the yolks and whites of the eggs, and pour them into the cream; mix together the flour and spices, and add the moist ingredients, stirring all together for an hour. The lightness of cakes is improved by thoroughly incorporating together all the ingredients of which they are composed.

5317. *Plain Seed Cake.*—The ingredients are, 2 lbs. of flour, ½ lb. of butter, a tablespoonful of fresh yeast, 2 eggs, 4 oz. of loaf-sugar, ½ oz. of caraway seeds. Dry the flour; beat the butter to a cream, adding to it a little milk and water, the sugar and the eggs, also well beaten; put the yeast to these ingredients, and pour them into the centre of the flour; work up the dough, and set it in the tin before the fire to rise. Bake it for an hour and a half.

5318. *Sponge Cake.*—The ingredients are, 10 eggs, their weight in fine sugar, the weight of six eggs of flour. Beat the yolks with the flour, the whites beat separately until they froth; by degrees mix in the sugar and the whites with the flour, and whisk all quickly together for half an hour. Put the mixture into tin moulds lined with buttered paper; cover the top of the cake with paper, and bake for an hour and a half.

5319. *Rice Cake (with butter).*—The ingredients are, 1 lb. of butter, 1 lb. of sugar, 12 eggs, ½ lb. of flour, and ½ lb. of rice flour. Beat the butter to a cream; add to it the sugar pounded; stir them till they appear light; break in the eggs three at a time, stirring the whole all the time. The eggs being worked in, add the rice and flour, previously mixed together. Bake this in a hoop, covering the top and bottom with several folds of paper.

5320. *Paper Cases for Sponge or Rice Cakes.*—These cases are generally made in the form of fluted baskets; the paper is cut somewhat larger than the moulds on which they are to be formed. A circular piece of paper, of proper size, is folded like the plaits of a shirt; then put on the mould, which fits tight into a wooden box, into which the mould is forced. The paper rising above the mould is neatly cut off, and when removed from the box the paper will be found of a firm shape; it is then iced with cream sugar inside and out, and put into the oven for a short time. It is then ready to receive the cake which is to be baked in it.

Subsect. 2.—*Biscuits.*

5321. *Champagne Biscuits.*—The ingredients are, 1 lb. of butter, 2 lbs. of flour, 1 lb. of loaf-sugar, 12 eggs, and 1 oz. of caraway seeds. The eggs and sifted sugar must be mixed together until they form a thick paste; the butter must be previously beaten to a cream, that, when the sugar and eggs thicken in stirring, the butter may be ready to stir in with them. The flour is then added by degrees, and the caraway seeds at the same time. Put the biscuits on crinkled paper, and the papers into the tin moulds; bake them in a hot oven.

5322. *Savoy Biscuits.*—The ingredients are, 15 eggs, 1 lb. of sifted sugar, ½ lb. of flour, and the raspings of the peel of two lemons. The eggs must have the whites and yolks beaten separately; the sugar and the lemon peel are next added to the yolks, and the whole beaten with two little wooden spaddles, one in each hand, rolling them like drum-sticks, to make the mixture froth. This must be continued for a quarter of an hour, during which time an assistant must be preparing the whites by beating them with a brisk whisk. They are, while in a state of froth, gently added to the yolks and sugar, during which time the whole must be constantly stirred, and the flour sifted in by an assistant, the stirring being still continued. When well mixed, the paste which is thus formed is spread on sheets of paper, in lengths of three and a half inches. When the papers are filled, finely-powdered sugar is sifted over them through a lawn or silken sieve; after remaining for a few minutes while the sugar settles in the biscuits, put them on plates and bake them of a fine clear colour; when cold, detach the pieces from the paper with the back of a knife, and lay them back to back.

5323. *Gimblettes.*—The ingredients are, 3 eggs, 6 oz. of flour, 4 oz. of sugar, and a little raspings of lemon peel. Break the eggs, and add to them the sifted sugar and rasped lemon peel; work them together, and then add flour until the paste is neither too stiff nor too soft for rolling. Roll it and cut it in form of rings about the size of a five-shilling piece; dip these rings into boiling water, taking them out as soon as they rise to the surface; drain them on a napkin, and put them on paper or plates to bake, in an oven moderately heated. When nearly done, with a brush lightly wash them with white of eggs, put them into the oven for a minute to dry.

5324. *Scotch Short-bread.*—The ingredients are, 1 lb. of butter, 2 lbs. of flour, ½ lb. of good brown sugar, ¼ lb. of blanched almonds cut small, and ¼ lb. of candied peel. Beat the butter to a cream, and add it to the flour and sugar with the other ingredients. When well kneaded and incorporated, roll it out into cakes about an inch thick. Bake it in a moderate oven.

5325. *Macaroons.*—The ingredients are, ¼ lb. of sweet almonds, 4 spoonfuls of orange-flower water, 6 whites of eggs, and 1 lb. of sifted sugar. Blanch and pound the almonds with the orange-flower water, or with some of the whites of eggs, if the flavour of orange-flowers is not approved of. Whisk the whites, and add them gently to the pounded almonds, lest they should not be properly incorporated with it, and should "oil," as the confectioner would say. Sift the sugar into the almonds till the whole forms a paste, not too stiff to be dropped on wafer paper, which must be spread ready to receive them on an oven plate. When dropped, wet a spoon, that the paste may not adhere to it, and flatten and round each macaroon till of a good shape. Bake them in a very slow oven. (Bitter macaroons are made in the same way, but with *bitter* instead of *sweet* almonds.)

5326. *Light Macaroons.*—The ingredients are, ¼ lb. of bitter, and ¼ lb. of sweet almonds, 1 lb. of sifted sugar, and 4 whites of eggs. Blanch the almonds, but, instead of pounding, cut them into small pieces, and moisten them with the white of one egg, and sift the sugar over them; then put them into the oven till they brown. Beat to a froth the rest of the eggs, and add them to the paste, whisking the whole together; drop them on wafer paper spread on the tin oven plate, and shape them with a spoon dipped in cold water. Bake them in a very slow oven. Cut the wafer paper round each macaroon, but leave it on the under surface.

5327. *Ratafia Biscuits.*—The ingredients are, ½ lb. of bitter and ½ lb. of sweet almonds, 2 lbs. of sugar, and 7 whites of eggs. Blanch and pound in a mortar with the whites of the 7 eggs the bitter and sweet almonds. They must be finely pounded before the sugar is added, which must be sifted into the mortar, and then worked in very thoroughly with the pestle for a quarter of an hour. These biscuits will not be good unless the sugar be very well incorporated with the other ingredients. Wash a bladder very clean, cut a small hole at one end of it, and fasten a glass tube to it, of the size of the biscuit required; then put into the bladder the ratafia paste, and press it gently through the tube in distinct drops on a thick white paper; drop the biscuits so that they do not touch each other. Bake them on tin plates in a warm oven. If the paper sticks to the biscuit when baked, it must be slightly wetted, when it can be easily removed, but the ratafias must in that case be put into the oven again to dry.

5328. *Almond Wafers.*—Ingredients, ½ lb. of sweet almonds, ¼ lb. of sifted sugar, 1 oz. of flour, and 2 eggs. Blanch and cut the almonds small; moisten them with the yolks and whites of eggs previously beaten. Sift into them the sugar and the flour, and mix the whole together with two drops of essence of lemon peel. Lightly butter a clean tin, and spread the mixture over it as thin as possible. Bake it of a light brown, and cut it with a knife, before it is cold, into long squares; roll them immediately on pieces of wood, to make them round and hollow. They are usually served to garnish creams.

5329. *Dry Meringues.*—Ingredients, 12 whites of eggs and 1 lb. of sugar. Beat up the 12 whites of eggs; when they are of a stiff froth, add to them the pound of sifted sugar, with some essence to flavour, either that of cloves, cinnamon, or lemon peel. Lay out the paste on paper in the form of large eggs halved; cover them with sugar, sifted through a silk sieve, and remove with a feather the surplus sugar. On a board two inches thick put the meringues to bake, for they must have no heat but from the top; when of a fine colour, remove the papers from them, and beat in, with the back of a spoon, the liquid part to form a hollow. Put them back again into the oven, to dry the inside, which is to be filled at the moment they are to be served, either with a cream or a jelly. Meringues are varied in colour and form, and may be ornamented with currants or almonds.

CHAPTER II.

ICES AND COMPOTES.

5330. In this chapter, under different sections, will be found some suggestions concerning *ices* and *compôtes*, and some receipts for the guidance of novices in either branch of confectionery. Those of *compôtes* are introduced in this chapter as being generally accompaniments of *ices.*

SECT. I.—ICES.

5331. *Ices are composed,* it is scarcely necessary to say, of congealed cream or water, combined sometimes with liqueurs or other flavouring ingredients, or more generally with the juices of fruits. At desserts, or at some evening parties, ices are scarcely to be dispensed with. Yet, in London, or in other great towns, these delicacies need not, neither can they often be of domestic manufacture. There the confectioner by trade can supply them more easily, and at a less cost than can be effected in all general cases at home; but, in country places, circumstances being different, the confectioner not being close at hand, the forming of ices, together with the preparing of other accompanying luxuries, must necessarily be a domestic concern; thus, an ice-house is convenient, for the construction of which see Book VIII., Chap. VII. Also, some suggestions and instructions in this work will be useful to the more youthful, if not to the experienced domestic manufacturer of these luxuries.

5332. *Preliminary Notices.*—The principal utensils required for making ice creams are, ice-tubs, freezing pots, spaddles, and a cellaret.

The tub must be large enough to contain about a bushel of ice, pounded small, when brought out of the ice-house, and mixed very carefully with either *salt, nitre,* or *soda.*

The freezing pot is best made of pewter. If it be of tin, as is sometimes the case, the congelation goes on too rapidly in it for the thorough intermingling of its contents, and on which the excellence of the ice greatly depends.

The spaddle is generally made of copper, kept bright and clean.

The cellaret is a tin vessel, in which ices are kept for a short time from dissolving.

The method to be pursued in the freezing process must be attended to. When the ice-tub is prepared with fresh-pounded ice and salt, the freezing pot is put into it up to its cover. The articles to be congealed are then poured into it, and covered over. But to prevent the ingredients from separating, and the heaviest of them from falling to the bottom of the mould, it is requisite to turn the freezing pot round and round by the handle, so as to keep its contents moving until the congelation commences. As soon as this is perceived (the cover of the pot being occasionally taken off for the purpose of noticing when freezing takes place), the cover is immediately closed over it, ice is put upon it, and it is left in this state till it is to be served.

The use of the spaddle is to stir up and remove from the sides of the freezing pot the cream which in the shaking may have washed against it, and, by stirring it in with the rest, to prevent any waste of it occurring. Any negligence in stirring the contents of the freezing pot before congelation takes place will spoil the whole. Either the sugar sinks to the bottom and leaves the ice insufficiently sweetened, or lumps are formed, which disfigure and discolour it.

SECT. II.—CREAMS FOR ICES.

5333. No. 1. *Ingredients:* One pint of cream, eight yolks of eggs, and lemon peel thinly pared. Beat the yolks of the eggs, and mix them gently with the cream; add the lemon peel, pared extremely fine; put the whole into a well-tinned, or bell-metal sauce-pan· being set over a slow fire, the contents of the sauce-pan must be stirred constantly with a whisk, until the cream begins to thicken. As soon as this is perceived, by the cream moving round the sauce-pan less easily, it must be taken off the fire, but the stirring must be continued for a short time, and at intervals, until the cream is cool. Great care must be taken in preventing it while on the fire from boiling, which would curdle it. When cool, a little sifted sugar may be stirred in, and the whole strained into a basin until wanted. In this state it is ready to have any flavour given to it which may be required.

5334. No. 2. *Whipt Cream.*—The ingredients are, one quart of cream, sugar to the taste. (To these flavours, either of orange flower water, or of lemon juice and wine, may be given, according to the use for which the cream is intended; but when to be used for ices, the orange flower water is the most general flavouring ingredient employed.) Put the cream, the orange flower water, and sugar into a bowl. Have at hand another basin with a silk sieve over it. Whisk the cream briskly, and as the froth rises to the surface, skim it off, and pour it into the sieve. Continue whisking and skimming, and pouring back into the bowl that part of the cream which passes through the sieve. When the whole of the cream is thus whisked, it may stand in the sieve until wanted, or it may be iced, by putting the sieve into a cellaret filled with pounded ice and salt. With either this kind of cream, or with such as may be prepared according to the preceding receipt, most of the ice creams in general use may be formed.

5335. *Orgeat Ice Cream.*—The ingredients are, 1 oz. of sweet almonds, ¼ oz. of bitter almonds, 1 pint of cream, 8 yolks of eggs, 4 oz. of sifted sugar. Blanch and pound the almonds with a little orange flower water. Beat the yolks, add the sugar, and stir all together gently into the cream. Put the whole on the fire, and whisk it round and round till it begins to thicken. Take it off, stir till cold, then put it into the freezing pot, and work as before directed.

5336. *Strawberry Ice Cream.*—The ingredients are, one pint of strawberries, one pint of thick cream, the juice of half a lemon, sugar to the taste. Mash and strain the juice of the strawberries, add to them some sugar finely pounded, and the cream fresh and thick. Squeeze and strain the juice of half a lemon into the strawberries and cream. Pass the whole through a sieve into the freezing pot, and work as before directed. In this cream, as well as in others, there should be no preponderance either of the flavour of the strawberries or lemon.

5337. *Raspberry, currant and raspberry, and pineapple ice creams* are all made in the same way as strawberry ice cream.

SECT. III.—WATER ICES.

5338. *These ices are made of the juice of ripe fruits* strained, and sweetened with clarified sugar, and put into the freezing pot, and worked as before directed. Sometimes the mixture is flavoured with a little lemon juice, or, if the freezing is not complete, water is added to the juice, but in a small quantity, or the mixture will become too solid. When congealed, it should be perfectly smooth, and soft enough to break easily with the spoon.

5339. *To currant water ice* the juice of raspberries, or of Kentish cherries, is sometimes added to soften the acid of the currant juice.

5340. *To cherry ice* a flavour of noyeau is sometimes added.

5341. *To apricot ice* the kernels blanched and pounded with a little sugar, some lemon juice, and a little water are added, care being taken to strain the whole free from every lump before it is put into the freezing pot.

5342. *Lemon water ice* is composed of the juice of lemons, into which the peel of one lemon out of four is finely rasped into the juice. A sirup of clarified sugar is added in a quantity sufficient to sweeten the whole, which must be carefully strained through a lawn sieve, before it is put into the freezing pot and worked.

To this ice ginger may be added, or liqueurs, such as Maraschino, or wines, such as Champagne, Madeira, &c.

SECT. IV.—COMPOTES.

5343. *Compôtes are fruits prepared in sirup* for immediate use, and chiefly as accompaniments of ices. In winter, or when fresh fruits are not to be had, the compotier must be supplied with preserved fruits, prepared in a manner similar to that in which the fresh fruits are formed into compôtes.

5344. *Green Apricot Compôte.*—Of this fruit is made a very favourite compôte. The thinning of an apricot-tree will often supply the fruit, which should be gathered for this purpose before the stones become hard. The down upon them must be removed by scalding them in water in which wood ashes or charcoal had been previously boiled, but strained off. The apricots are thrown in when the water is hot, and as they rise to the surface are skimmed off, and immediately thrown into cold water. They are taken out of the cold water, drained, and rubbed with a cloth. When the down is cleaned off, the fruit must be put into a hot sirup, and then, after once boiling up, and being well scummed, they must be poured into a basin till the succeeding day. The sirup is then drained from them, boiled up, and poured over them again, with some fresh sirup added to it. The apricots and sirup are then boiled up for four or five days successively, more sirup being added as it is washed in each day's boiling. When boiled up for the last time, the apricots must be taken out, the sirup boiled to the great thread, and poured over the fruit, which is then ready for the compotier. This compôte will be scarcely good if kept more than two days.

5345. *Ripe Apricot Compôte.*—Peel, divide into halves, and stone some fine ripe apricots. Prick them all over with a needle. Blanch them carefully, and drain the water from each by gentle pressure. Put them in sirup, and boil them up; scum the sirup; let the whole stand to cool, then boil the sirup, and pour it over them several times successively.

5346. *Ripe Plum Compôte.*—Prick the plums with a needle, and put them into cold water while boiling a pan of water, into which they must be put as soon as the water boils. When the fruit rises to the surface, take them out of the hot water, and put them again into cold water. Prepare the sirup for them, and boil them up in it. Pour them into a basin, and leave them for some hours, and then boil them up once or twice more; scum them well, and let them cool for use.

5347. *Strawberry Compôte.*—Strawberries for a compôte require very little boiling. It is sufficient to pour over them some currant jelly boiling.

5348. *Raspberry Compôte.—Raspberries, as well as strawberries, are too delicate* a fruit to require much boiling. When they have been carefully selected for their size and ripeness, they must be washed in cold water and drained. The sirup must be, while boiling, poured over them. In this sirup they must remain four or five hours, then be put into a bell-metal sauce-pan, and be warmed in the sirup, not boiled, or they will be broken and disfigured. When cool, they are ready for the compotier.

5349. *Apple Compôte.*—Peel, cut into halves, and core some apples; and after letting them lie for a short time in cold water, drain them, and put them into sirup, in which boil them till they are soft; then place them in the compotier, and strain the sirup over them. Remember that with apples the flavour of lemon peel is generally liked. This compôte may be improved by boiling in the sirup some of the apple to a jelly, straining it, and pouring it over the halves prepared as above directed.

5350. *Orange Compôtes.*—Peel either some China or St. Michael's oranges, cut them into slices, and remove the pips, if there be any in them. Boil some sirup, but do not pour it over the sliced oranges till it is cold. This compôte requires no boiling.

CHAPTER III.

CONFECTS FOR DESSERTS AND ROUTS.

SECT. I.—DRY CONFECTS.

5351. Under this head we shall only include *fruit in candy*, *fruit in pastes*, *fruit in biscuits*.

SUBSECT. 1.—*Candied Fruits.*

5352. *Apricots*, *cherries*, *greengages*, *barberries*, *oranges*, and any other fruits that have been previously preserved in *sirup*, may be candied by following the directions now given. For candying there must be provided two square boxes; one made of tin, about twelve inches long, eight inches wide, and about three or four inches deep. At one corner of this box there must be a hole and pipe, through which overflowings of sirup may pass off, but which must be corked up while the fruit is in the oven. The other box must be made entirely of wire, and somewhat smaller than the other; to this last there must also be a cover. The fruit which is to be candied is placed in layers one above another, on wire frames, and when the wire box is completely filled, the cover is put on to keep the contents in place, and the box is placed within the tin box, and put into an oven moderately heated. The second case must also be covered closely before it is put into the oven.

The mode of candying is by boiling sirup to what is termed the "*little blow.*" (See Book X., Chap. IV., Sect. VIII., "Preserving by Sirup.") Let a pint of sirup be boiled to this degree. While cooling, the surface of the sirup will be covered with candy, which, as it forms, must be skimmed off, and poured in among the layers of fruit after they are placed in the wire box. When the whole of the sirup has been thus used, then the box containing the fruit must be covered closely, put into the oven, and suffered to remain in it for twelve hours. When taken out, the wire case must be placed so as to allow all the sirup which has not candied to pass away. As soon as the moisture dis appears, the fruit must be taken out with great care, and put into tin boxes, to be kept dry until wanted.

5353. *Orange chips* are prepared from the parings of Seville oranges, and in the same way as directed in the preceding receipt for candying orange and lemon peel.

5354. *Candied Ginger.*—Put into a preserving-pan one ounce of finely-grated ginger, one pound of sifted loaf-sugar, and no more water than enough to dissolve the sugar. Put the pan over a slow fire till the sugar begins to boil. Add another pound of finely-sifted sugar, stirring it in till it thickens, then drop it in cakes or plates, and dry them in a slow oven; when done they will be hard, brittle, and white.

SUBSECT. 2.—*Fruits in Paste.*

When the pulp of any fruit is boiled to such a consistence as to keep in the form given to it, it is called "paste;" and, made up in different forms, it adds variety to desserts at seasons when many fresh fruits are not to be had.

5355. *Apple Paste.*—Apples, boiled till soft, peeled, and passed through a hair sieve, to be formed into "paste," must be slowly boiled in sirup until it is perceived to thicken; it is then ready to be put into moulds, or dropped on plates as cakes. The plates and moulds must then be put into a slow oven, and left in it for twenty-four hours, or longer, if the pulp is not sufficiently dried to turn out of the moulds, or to cut into rings and circles, or into stringlets by which knots may be formed.

5356. *Apricot Paste.*—Boil a dozen ripe apricots for two or three minutes, pass them through a hair sieve, and reduce the pulp they render by boiling it for some time before adding the sirup to it. Remember, it must be stirred the whole time. For every pound of pulp weigh half a pound of sugar, which must be clarified and boiled to "a feather" (see "Preserving by Sirup," Book X., Chap. IV., Sect. VIII.), before the pulp is added to it. The pulp and sugar must not be boiled together for more than a minute, when the moulds must be filled and the paste dried, as before directed, in a slow oven for twenty-four hours. Wooden moulds lined with loose paper answer the best for these pastes. When the paper is to be taken off, it must be wetted in a little warm water.

5357. *Greengage Paste.*—Boil greengages to a jam without sugar, pass them through the sieve, and again reduce them in the preserving-pan over the fire. To every pound of pulp weigh a pound of sugar; clarify it, and boil it to the "great ball." (See "Preserving by Sirup.") Mix the pulp with it, and boil both together for a few minutes, when it may be poured into moulds or on plates, and dried as directed for other pastes.

5358. *Raspberry and Strawberry Pastes.*—These fruits may both be made into pastes by the same means as above directed in regard to other fruits. More sugar is, however, requisite to make them harden properly: about a pound and a quarter to a pint of pulp will be sufficient; and after clarifying it, both are boiled for a short time, and dried as before directed.

Every fruit paste may be candied by adding sifted sugar to them, and continuing to keep them in a stove of moderate heat.

SUBSECT. 3.—*Fruits in Biscuit.*

5359. *Biscuits of fruit are composed* of the pulp of scalded fruit, with sifted sugar of weight, in most cases, equal to that of the pulp, sometimes greater. When mixed, these ingredients are dried in the oven, the heat of which should never be such as to bake, instead of drying them.

5360. *Apricot Biscuits.*—Peel and reduce as many ripe apricots as will yield one pound of pulp; stir in a pound of fine loaf-sugar sifted, and boil both pulp and sugar together for about a quarter of an hour; then pour the jam thus made into paper cases, or drop it on paper in the form of small cakes, and dry them in a slow oven, or before a fire, for several days, turning them each day. Put them in boxes or tins, and keep them dry for winter use.

5361. *Apple Biscuits.*—Slightly flavour the pulp of apples with essence of lemon peel; mix with it, while warm, its weight of sifted sugar, and drop it on plates or into paper cases, and dry it in a slow oven for several days.

5362. *Raspberry Biscuits.*—Carefully select fine raspberries, and clear them of any that appear too ripe or mouldy; weigh them before reducing them to a pulp, that an equal quantity of sugar may be added to them when reduced. When they are sufficiently reduced, take them off the fire, and mix in the sugar, finely pounded and sifted; stir it in till it is dissolved; then pour the paste out on plates, to dry it. As soon as the surface at the top is dry, cut the paste into cakes of different forms; turn them, and continue to dry them in a slow oven until they are crisp. Put them into boxes or tin cases, and keep them in a dry place.

Strawberry biscuits are made in the same way.

SECT. II.—LIQUID CONFECTS.

5363. *Iced fruit waters* are, in their season, very agreeable and elegant beverages for evening parties. Either *currants*, *cherries*, *strawberries*, *raspberries*, or *apples* may be employed for this purpose.

5364. *Strawberry Water.*—Take a pottle, if possible, of scarlet strawberries, on account of the beautiful colour they impart to the sirup, pick them carefully, and put them into three pints of very weak sirup; bruise the strawberries in it, and boil them up; strain the water through a jelly-bag without any pressure, which would render the water thick. Ice the water, and keep it in a cool place till wanted.

In making currant and cherry waters, a stronger sirup will be required than for strawberries: the taste must determine the requisite strength for it.

Orgeat Water.—Blanch and pound rather more than half a pound of sweet almonds, and about a dozen of bitter; add to them a quart of weak sirup, with as much orange flower water as may pleasantly flavour the water. Boil these together, and strain off the water through the jelly-bag, or tamis; bottle it, and ice it. To this some add the flavour of cinnamon; others that of brandy.

Orange Water.—Take the rinds of six China oranges, cut them into small shreds, and put them into two quarts of boiling water; squeeze the juice of the oranges into it; add sugar to the taste, finely sifted; boil all together, and strain the water through the jelly-bag; bottle, and ice it.

5365. *Lemonade.*—Pare off very thin the rinds of twelve lemons; put about half of these parings into three pints of hot water, and cover it over for two hours; squeeze the juice of the lemons into a China bowl, and add to it a pound and a half of fine sugar (pounded); add to this the water, and three pints of milk, boiling hot; pour this through a jelly-bag, and continue to do so until the lemonade is perfectly clear. If not sufficiently flavoured with the essence of the peel, a few drops of the prepared essence of lemon peel should be added; bottle, and ice it. *Lemonade* made with boiling water and slices of lemon, together with sugar enough to sweeten it, and a quarter of an ounce of isinglass dissolved in it, forms an agreeable beverage, and is made with less trouble than that made after the above receipt. It requires also to be passed through the jelly-bag, and to be bottled and iced.

Raspberry Vinegar.—Put a pound of fine raspberries into a *China* bowl, or glass dish, and pour over them a quart of white wine vinegar. The next day strain the liquor from the raspberries, and pour it over another pound of fresh fruit, and thus increase the quantity daily, until enough juice has been obtained. Let it be remembered that the juice must only be *drained*, not squeezed from the fruit, or the vinegar will be turbid. To every pint of the juice thus obtained weigh a pound of loaf-sugar; break it into moderate-sized lumps; add it to the vinegar, and keep stirring it at intervals until it is dissolved. Put all together into a stone jar, which set in hot water, or on a hot hearth, where it must simmer for some time, must be skimmed, when cold, bottled, and the cork closed over with sealing-wax or with bladder.

5366. *Capillaire.*—Take seven pounds of loaf-sugar, one pound of moist sugar, and four eggs, well beaten, put these into three pints of water; boil it up two separate times; skim it carefully while boiling; add to it a quarter of a pint of orange flower water; strain it through a jelly-bag, and bottle it when cold. A spoonful in a tumbler of cold water makes a pleasant beverage.

BOOK XVI.

COOKING FOR THE ECONOMIST AND INVALID.

CHAPTER I.

COOKING FOR THE ECONOMIST.

Among the foregoing receipts will be found many which, by the economist, would be considered as leading to a prodigal use of the ingredients composing our daily food; and, in the case of householders of small income, the application of those receipts could not, indeed, be otherwise regarded. Health in the body and comfort in the spirits, to be sustained, demand a daily sufficiency of food, properly cooked. A single joint, well cooked and neatly served, ought, to persons in health, to afford a dinner sufficiently nourishing and enjoyable; but when this can be varied by the art of cooking, without increasing imprudently the expenditure, there can be no objection to its being done; on the contrary, it is only co-operating with the benevolent intentions of nature to render the meals of those who earn their food fully relishing.

Sometimes the situation in life requires not only economy, but something of style to be supported. When this is the case, a really good cook is a valuable person in a family: she will know how to turn everything to account; how to produce from an old basis a new dish; and how to serve up, in some form or other, to-day the superabundance of the dinner of the previous day. Ideas and suggestions on these points will be found in the present chapter: they are offered as assistance to the novice in domestic economy, but who, in following them up, will find some that may not be in her case capable of application; some that must be modified before they are adopted; others that must be improved upon.

Sect. I.—BUTCHER'S MEAT, FISH, AND POULTRY.

Subsect. 1.—*Economy in the Use of Butcher's Meat.*

5367. *Of beef, the round* is, in large families, one of the most profitable parts: it is usually boiled, and, like most of the boiling parts of beef, is generally sold, in London, at a penny per pound less than the roasting joints.

5368. *The brisket* is also a penny a pound less in price than the roasting parts: it is not so economical a part as the round, having more bone to be weighed with it, and more fat. Where there are children, very fat joints are not desirable, being often disagreeeble to them, and sometimes prejudicial, especially if they have a dislike to it. This joint also requires more cooking than many others; that is to say, it requires a double allowance of time to be given for boiling it: it will, when served, be hard, and scarcely digestible, if no more time be allowed to boil it than that which is sufficient for other joints and meats. When stewed it is excellent; and when cooked fresh (*i. e.*, unsalted), an excellent stock for soup may be extracted from it, and yet the meat will serve as well for dinner.

5369. *The edgebone*, or *aitchbone*, is not considered to be a very economical joint, the bone being large in proportion to the meat; but the greater part of it, at least, is as good as that of any prime part. It sells at a penny a pound less than roasting joints.

5370. *The rump* is the part of which the London butcher makes great profit, by selling it in the form of steaks. In the country, as there is not an equal demand for steaks, the whole of it may be purchased as a joint, and at the price of other prime parts. It may be turned to good account in producing many excellent dishes. If salted, it is simply boiled; if used unsalted, it is usually stewed.

5371. *The veiny piece* is sold at a low price per pound; but, if hung for a day or two, it is very good and very profitable. Where there are a number of servants and children to have an early dinner, this part of beef will be found desirable.

5372. *From the leg and shin* excellent stock for soup may be drawn; and, if not reduced too much, the meat taken from the bones may be served as a stew with vegetables; or it may be seasoned, pounded with butter, and potted; or chopped very fine, and seasoned with herbs, and bound together by egg and bread crumbs: it may be fried in balls or in the form of large eggs, and served with a gravy made with a few spoonfuls of the soup.

5373. *Of half an ox cheek* excellent soup may be made: the meat, when taken from the bones, may be served as a stew.

5374. *Roasting parts of beef* are *the sirloin* and *ribs*, and these bear in all places the highest price. The most profitable of these two joints at a family table are the ribs. The bones, if removed from the beef before it is roasted, will assist in forming the basis of a soup. When boned, the meat of the ribs is often rolled up, tied with strings, and roasted; and this is the best way of using it, as it enables the carver to distribute equally the upper part of the meat with the more skinny and fatter parts at the lower end of the bones.

5375. *Of mutton, the leg and haunch* are the most profitable joints, although in price higher than the *shoulder* or *neck*. But these last joints are sold at a less price per pound than others.

The loin and saddle (the two loins not separated) are expensive joints, not in price only, but in the great proportion of fat and bone belonging to them. They are considered to be prime parts.

5376. *Lamb.*—The *hind* quarter is more advantageous in use than the *fore*, but can scarcely be regarded as an economical part. In hot weather, and in a small family, the joints which the quarters form, when divided, are of so convenient a size as to render them much in request.

5377. *Of veal, the leg*, from which the fillet is taken, *the shoulder, the neck, and the loin* are all, in turn, serviceable in a family. When the leg is purchased all together, without dividing the knuckle from it, the butcher usually considerably remits the price. In summer he is often willing to sell the leg all together at twopence per pound less than he would sell the fillet alone.

Subsect. 2.—*Economy in the Use of Poultry, Game, and Fish.*

5378. *Poultry and game* can only be considered as economical provisions in certain country districts. In town they are generally too dear to be often purchased by those who are obliged to study economy; and it may be well to remember that, although useful as food for invalids, being light, and not as stimulating as butcher's meat, these delicacies of the table are of less value in a family than the more substantial joints from the shambles. They are delicacies, but not essentials. Most of them require expensive gravies and sauces to render them agreeable as food.

5379. *Fish* may be occasionally useful in giving variety to the family table; but in London, except it be the most common kinds of fish, it cannot be regarded as among economical articles of food. It is not sufficiently nourishing to be employed as a substitute for animal food; and if it cannot be brought to table as a substitute, it is then a supernumerary dish, one that may be dispensed with, but which, when served, possesses little in its flavour to recommend it, unless accompanied with good and expensive sauces. In many maritime districts there is, it is true, such an abundance of fish, fresh, salted, and dried, as to render it the chief food of the immediate neighbourhood.

Subsect. 3.—*Hot Dishes prepared from cold Provisions.*

5380. *Cold meat goes farther in use than hot meat*, and by many persons it is preferred to the dishes prepared from it. But others, especially the aged, are better satisfied when the cold provisions are formed into warm and savoury hashes, minces, or ragoûts. When the appetite begins to decline from the debility of increasing years, it is very desirable to tempt it by any of the wholesome arts of cookery. By such means as are here about to be suggested, with very little additional expense, one day's dinner may supply two or more dishes for that of the succeeding day.

Roasted beef may be warmed again, as, 1. Lobscous; 2. Podovies; 3. Olives; 4. Fried (as Staffordshire beef-steaks); 5. Collops (with eschalot or walnut-pickle); 6. Hashed, and prepared like haricot mutton (with carrots, turnips, and onions); 7. Slices put into a pie-dish with a gravy, and seasoning of eschalots and pepper, then covered over with a coating of mashed potatoes, and baked before the fire. The fat of the inside of cold sirloin will make an excellent pie or pudding crust: the bones, well stewed with pease and onions, and seasoned with pepper and salt, form sufficient stock for old pea soup.

5381. *Cold boiled beef*, 1. Minced and warmed up in fresh beef gravy (flavoured with eschalot or onion); 2 Potted; 3. Fried with cabbage (bubble and squeak); 4. Fried with a casserole of mashed potatoes. The water in which beef has been boiled, if not extremely salt, may serve as the stock of pea or carrot soup.

5382. *Veal* may be recooked, 1. In thin slices, with white sauce; 2. Fried as cutlets (with egg and bread crumbs); 3. As a ragout (with green pease); 4. As curry (with rice); 5. Made into rissoles with grated ham; 6. Patties, with ham or oysters.

5383. *Calf's head, boiled*, makes an excellent hash: the gravy may be procured by reducing the liquor in which it was boiled. It is sometimes eaten cold with vinegar and mustard, like brawn.

5384. *Cold mutton* may be hashed in several ways: 1. It may be cooked like venison (with red wine and sweet sauce); 2. It may be simply *hashed*, and flavoured with mushroom catsup; 3. It may be made into haricot with vegetables; 4. Fried with egg and bread crumbs, and served with a made mutton gravy; 5. Broiled, and served on a rock of mashed potatoes.

5385. *Cold lamb* may be, 1. Fried, and put into a hot stew of cucumbers for a short time previous to serving; 2. Fried with egg and bread crumbs and chopped parsley, garnished also with sprigs of crisp parsley

Chops from cold loin may be fried, and served on a dish of spinach.

5386. *Pork, of cold leg or loin,* in slices or chops, will be excellent nicely fried in butter, and surrounded with a thick pucée of apples. *Pea soup* may be made of the liquor in which a leg has been boiled, if not too salt.

5387. *Cold Poultry.—Turkey,* which has been either boiled or roasted, may be again served, by pulling the fleshy parts from the bones, which must be warmed in a gravy made with the bones and carcass of the turkey, and thickened with cream; the legs, pinion, and gizzard should be highly deviled, broiled, and laid on the top of the hot mince. Cold fowls may be made into a good curry, and served with a turban of rice. *Cold goose or duck,* cut up and hashed in a good beef gravy, makes a very good entrée or remove. *From game* may be made *hashes,* salpiçons, emincés, and it may be potted.

5388. *Fish.—Cold salmon or mackerel* may be broiled or put into a pickle prepared with vinegar, diluted with some of the liquor in which the fish had been boiled, and seasoned with black peppercorns. *Cold codfish* may be spiced and potted, or made into curry.

Cold Vegetables.—1. Potatoes may be fried in slices, and used as garnish to beef or mutton; 2. Mashed and fried with beef or mutton; 3. Mashed and made into a crust with the yolk of eggs and some butter; 4. Made into casseroles for ragout or minces; 5. Made warm with gravy, and passed through a coarse sieve, or colander. Carrots, turnips, and cabbages may be warmed separately, or mingled in moulds, to be turned out when the dinner is served.

5389. *The dripping of roast meats* may be used instead of butter in the pastry of meat pies, for frying fish, fritters, and pancakes.

Top pot may be used as butter to thicken gravies, when mixed with flour.

Cold melted butter may be warmed by putting the jar or tureen containing it into boiling water, and covering it over, except when it requires to be stirred or shook up.

Eggs which have been boiled may be again made hot by putting them into a basin of hot water, and covering them over for five minutes.

Subsect. 4.—BILLS OF FARE FOR FAMILY DINNERS.

Number in Party from 10 to 12.

I.

First Course.

	Soup. (Remove, Boiled calf's head.)	
Potatoes.	Parsley and butter.	Tongue and brains.
	Horseradish sauce.	
Bacon.		Greens.
	Roast beef.	

Second Course.

	Batter pudding.	
Devonshire cream.	Sweet sauce.	Cheese-cakes.
Spanish fritters.	Tureen of sugar.	Rice blanc-mange.
	Apple tart.	

Estimate of the above.

	s.	d.
Soup made from beef bones, with vegetables, 6*d.* per quart	1	0
Calf's head (with the skin on)	4	0
2 lbs. of bacon, at 8*d.* per pound	1	4
10 lbs. of beef, at 9*d.* per lb.	7	6
Potatoes, 3*d.*; greens, 2*d.*; parsley and horse-radish, 3*d.*	0	8

	s.	d.
Pudding (milk, 2*d.*; eggs, 3*d.*; flour, 1*d.*; salt, butter, &c., 2*d.*)	0	8
Devonshire cream, 1*s.* 6*d.*; rice blanc-mange, 6*d.*	2	0
Spanish fritters, 4*d.*; cheese-cakes, 6*d.*	0	10
Apple tart	1	0
Total . . 19*s.*		

II.

First Course.

Soup. (Remove, Calf's head, brained.)	
Mashed potatoes.	Lobscous.
Fried bacon and poached eggs.	Stewed onions.
Roast neck of mutton.	

Second Course.

	Rice pudding.	
Puffs.		Slices of fried batter pudding.
Jelly, in shapes.		Baked currants, with leaves of pastry.
	Apple tart and custard.	

Estimate.

	s.	d.
Soup made of the liquor in which the calf's head had been boiled the day before, vegetables, &c.	0	6
Hashed head, gravies, &c.	0	6
Mutton, 5½ lbs., at 7½*d.* per lb.	3	5
Lobscous, made of cold roast beef, potatoes, onions, &c.	0	6
3 stewed onions, 2*d.* each	0	6
Eggs, 6*d.* (bacon taken from that in use the previous day)	0	4

	s.	d.
Mashed potatoes	0	4
Rice pudding	0	6
Apple tart and custard (the remains of yesterday's dinner put together)	—	
Puffs	—	
Slices of fried batter pudding (the remains of yesterday's dinner)	—	
Jelly, in mould	—	
Baked fruit, with pastry leaflets	0	10
Total . . 7*s.* 5*d.*		

III.

First Course.	*Second Course.*
Pea soup. (Remove, Boiled knuckle of veal.)	Fried rice pudding.
Spinach, with gravy.	Tartlets.
Calf's head hash.	Custard and stewed apples.
Piece of ham.	Lemon cream
Scolloped potatoes.	Cheese-cakes.
Mutton haricot.	French tart.

Estimate.

	s.	d.
Pea soup, made from roast beef bones and fresh vegetables	0	6
Knuckle of veal, 7 lbs., at 6*d.* per lb.	3	6
Remains of yesterday's mutton (haricot)	0	4
Calf's head hash (remains from preceding day's hash, with fresh gravy)	0	4
Spinach and gravy	0	6
Ham, 3 lbs., at 10*d.* per lb.	2	6
Potatoes	0	2
Fried pudding (left the preceding day)	—	
French tart	1	0
Tartlets and cheese-cakes	1	0
Stewed apples (with custard)	1	0
Total . . 10*s.* 10*d.*		

IV.

First Course.	*Second Course.*
White soup. (Remove, Rabbits.)	Macaroni pudding.
Mashed potatoes.	Fritters.
Fried veal in dice.	Preserves.
Curled bacon.	Jelly.
Carrots.	Puffs.
Boiled brisket of beef.	Plum tart.

Estimate.

	s.	d.
White soup, made of the liquor in which the knuckle of veal was boiled the previous day	0	3
Rabbits	2	6
Fried veal, cut in dice (remains of the knuckle)	—	
Curled bacon, 1 lb.	0	8
Brisket of beef, 10 lbs., at 6½*d.* per lb.	5	5
Potatoes and carrots	0	5
Macaroni pudding	1	0
Fruit tart	1	0
Fritters, 6*d.*, and puffs, 6*d.*	1	0
Preserves and jelly	2	0
Total . . 14*s.* 3*d.*		

V.

First Course.	*Second Course.*
Soup. (Remove, Boiled fowl.)	College pudding.
Bacon.	Jelly in glasses.
Beef baked with potatoes.	Puffs.
Fish. (Remove, Roast mutton.)	Stewed apples.

Estimate.

	s.	d.
Soup made of the liquor, reduced, in which the last day's beef was boiled, and with vegetables	0	6
Fowl, with parsley and butter	3	4
Fish (salmon), 3 lbs., at 1*s.* 6*d.* per lb.	4	6
Leg of mutton, 8 lbs., at 8*d.* per lb.	5	4
Bacon, 2 lbs., at 8*d.* per lb. (beef, with mashed potatoes)	1	8
College pudding	0	10
Stewed apples	0	6
Jelly, left the day before, put in glasses	—	
Puffs, left preceding day	—	
Vegetables on side table	0	8
Total . . 16*s.* 6*d.*		

VI.

First Course.	*Second Course.*
Soup. (Remove, Hashed mutton.)	Fruit pudding
Potatoes.	Stewed apples.
Spinach.	Custards.
Roast beef.	Macaroni.

Estimate.

	s.	d.
Soup (left preceding day), fresh vegetables boiled in it	0	4
Hashed mutton (prepared from cold mutton of the preceding day's dinner), catsup, and vegetables	0	4
Roast beef, 10 lbs., at 8*d.* per lb.	6	8
Vegetables	0	6
Fruit pudding	0	9
Macaroni (cheese grated from pieces which would not do for the table)	1	0
Stewed apples (left the day before)	—	
Custards	1	6
Total . . 11*s.* 1*d.*		

SIX DINNERS FOR A FAMILY PARTY CONSISTING OF TWELVE INDIVIDUALS.

	s.	d.		s.	d.
1st day	19	0	5th day	16	6
2d day	7	5	6th day	11	1
3d day	10	10	Total . £3 19s. 1d.		
4th day	14	3			

SECT. II.—RECEIPTS FOR COOKING COLD PROVISIONS.

SUBSECT. 1.—*Modes of cooking cold Butcher's Meat.*

5390. *Minced Beef.*—Cut into small dice remains of cold beef; any gravy reserved from it on the first day of its being served should be put in the stew-pan, with the addition of warm water, some mace, sliced eschalot, salt, and black pepper. Let the whole simmer gently for an hour. A few minutes before it is served, take out the meat and dish it; add to the gravy some walnut catsup, and a little lemon juice or walnut pickle. Boil up the gravy once more, and when hot pour it over the meat. Serve it with bread sippets.

5391. *Cold roast Beef (with mashed Potatoes).*—Mash some potatoes with hot milk, the yolk of an egg, some butter, and salt. Slice the cold beef and lay it at the bottom of a pie-dish, adding to it some sliced eschalot, pepper, salt, and a little beef gravy; cover the whole with a thick paste of potatoes, making the crust to rise in the centre above the edges of the dish. Score the potato crust with the point of a knife in squares of equal sizes. Put the dish before the fire in a Dutch oven, and brown it on all sides; by the time it is coloured, the meat and potatoes will be sufficiently done.

5392. *Bubble and Squeak.*—Cut into pieces, convenient for frying, cold roast or boiled beef; pepper, salt, and fry them; when done, lay them on a hot drainer, and while the meat is draining from the fat used in frying them, have in readiness a cabbage already boiled in two waters; chop it small, and put it in the frying-pan with some butter, add a little pepper and salt, and keep stirring it, that all of it may be equally done. When taken from the fire, sprinkle over the cabbage a very little vinegar, only enough to give it a slight acid taste. Place the cabbage in the centre of the dish, and arrange the slices of meat neatly round it.

5393. *Lobscouse.*—Mince, not too finely, some cold roast beef or mutton. Chop the bones and put them into a sauce-pan with six potatoes peeled and sliced, one onion, also sliced, some pepper, and salt; of these make a gravy. When the potatoes are completely incorporated with the gravy, take out the bones, and put in the meat; stew the whole together for an hour before it is to be served.

5394. *Beef Rissoles.*—Mince and season cold beef, and flavour it with mushroom or walnut catsup. Make of beef dripping a very thin paste, roll it out in thin pieces about four inches square; enclose in each piece some of the mince, in the same way as for puffs, cutting each neatly all round: fry them in dripping of a very light brown. The paste can scarcely be rolled out too thin.

5395. *Minced Veal.*—Cut veal from the fillet or shoulder into very small dice; put it into veal or mutton broth, with a little mace, white pepper, salt, some lemon peel grated, and a table-spoonful of mushroom catsup or mushroom powder, rubbed smooth into the gravy. Take out some of the gravy when nearly done, and when cool enough thicken it with flour, cream, and a little butter; boil it up with the rest of the gravy, and pour it over the meat when done. Garnish with bread sippets. A little lemon juice added to the gravy improves its flavour.

5396. *Cold Veal dressed with White Sauce.*—Boil milk or cream with a thickening of flour and butter; put into it thin slices of cold veal, and simmer it in the gravy till it is made hot without boiling. When nearly done beat up the yolk of an egg, with a little anchovy and white sauce; pour it gently to the rest, stirring it all the time; simmer again the whole together, and serve it with sippets of bread and curled bacon alternately.

5397. *Veal Rissoles.*—Mince and pound veal extremely fine; grate into it some remains of cooked ham. Mix these well together with a white sauce flavoured with mushrooms; form this mixture into balls, and enclose each in pastry. Fry them in butter of a nice brown.

The same mince may be fried in balls without pastry, being first cemented together with egg and bread crumbs.

5398. *Mutton, hashed.*—Cut cold mutton into thin slices, fat and lean together; make gravy with the bones whence the meat has been taken, boiling them long enough in water, with onion, pepper, and salt; strain the gravy, and warm, but not boil the mutton in it. Then take out some of the gravy to thicken it with flour and butter, and flavour it with mushroom catsup. Pour in the thickening and boil it up, having before taken out the meat and placed it neatly on the dish in which it is to go to the table. Pour over it the boiling gravy, and add sippets of bread.

5399. *Cold Lamb.*—Fry slices or chops of lamb in butter till they are slightly browned. Serve them on a purée of cucumbers, or on a dish of spinach; or dip the slices in bread crumbs, chopped parsley, and yolk of egg; some grated lemon peel and a little nutmeg may be added. Fry them, and pour a little nice gravy over them when served.

5400. *Cold Pork.*—Slices of cold pork, fried and laid on apple sauce, form an excellent side or corner dish. Boiled pork may also be made into rissoles, minced very fine like sausage meat, and seasoned sufficiently, but not over much.

SUBSECT. 2.—*Cooking cold Poultry and Game.*

5401. *Cold Fowl (made into Fricassée).*—Cut up a cold boiled or roasted fowl; put it into a stew-pan with a pounded bitter almond, a little mace, grated lemon peel, and white pepper and salt; cover it with warm water or with broth of boiled fowl, and put on the sauce-pan cover; set the sauce-pan near the fire to simmer for half an hour. When near the time of serving, thicken some of the gravy with flour and butter, and with cream or with the yolk of an egg; make it hot, pour it over the meat, and serve with sippets and curled bacon. If the gravy be suffered to boil after the cream or egg has been added, it will probably curdle the gravy. Whenever it begins to boil, it should be taken off the fire.

Cold fowl may be served with a salpiçon or emincé put within it. (See "French Cooking Receipts.")

5402. *Cold Rabbit.*—Dress cold rabbit the same as cold fowl, either as a fricassée, a curry, or a salpiçon

5403. *Cold hare* may be hashed with good beef gravy, and served with currant jelly sauce.

SUBSECT. 3.—*Warming up cold Fish.*

5404. *Salmon and Mackerel.*—When brought from table, any remains of salmon or mackerel should be soused in a pickle made with some of the water in which the fish had been boiled, and with vinegar and black peppercorns. By this means the fish may be kept, if requisite, for several days, and is then relished by those who eat suppers.

5405. *Cod.*—The remains of this fish may be employed as the basis of a curry; or it may be put into a dish, and, with bread crumbs, butter, and eggs, it may be made brown, and serve as a corner or flank dish the second day.

SUBSECT. 4.—*Warming up Vegetables left at Table.*

5406. *Cold potatoes*, cut into thin slices, floured, salted, and fried in butter, make an excellent and relishing dish, to be eaten either alone or with any insipid meats.

5407 *Cold Potatoes, scolloped.*—Bruise cold potatoes in a mortar or potato bowl. Beat well the yolk of an egg, and mix it with warm milk, with some salt, and a small lump of butter; rub the potatoes perfectly smooth, and incorporate this mixture with them; put it into a scollop shell, score it over the surface, and put on it some small bits of butter; brown it in a Dutch oven or with a salamander.

5408. *Mashed Potatoes and Spinach or Cabbage.*—Moisten *cold mashed* potatoes with a little white sauce; take cold cabbage or spinach, and chop either one very finely. Moisten them with a brown gravy. Fill a tin mould with layers of potatoes and cabbage, cover the top, and put it into a stew-pan of boiling water. Let it remain long enough to warm the vegetables; then turn the vegetables out and serve them. This might be prepared by boiling the vegetables separately, and merely putting them into the mould in layers, to be turned out when wanted. It forms a very pretty dish for an entrée.

5409. *Carrots and turnips may be added to soups*, if they have not been mixed with other gravies, or warmed up separately, and put into moulds in layers; they may be turned out, and served the same as the potatoes and cabbage described above.

Subsect. 5.—*Cold sweet Dishes.*

5410. *Cold Rice Pudding.*—Over cold rice pudding pour a custard, and add a few lumps of jelly or preserved fruit. Remember to remove the baked coating of the pudding before the custard is poured over it.

5411. *Apple Tart.*—Cut into triangular pieces the remains of a cold apple tart; arrange the pieces around the sides of a glass or china bowl, and leave space in the centre for a custard to be poured in.

5412. *Cold Plum Pudding.*—Cut into thin round slices cold plum pudding, and fry them in butter. Fry also Spanish fritters (see "Receipts"), and place them high in the centre of the dish, and the fried pudding all round the heaped-up fritters. Powder all with lump sugar, and serve with wine sauce in a tureen.

Any kinds of jellies and blanc-manges may be, if broken into, dissolved over the fire, and put into fresh moulds to be turned out for another day's dinner.

CHAPTER II.

COOKING FOR THE INVALID.

Sect. I.—GENERAL OBSERVATIONS.

5413. Some apology may be considered requisite for introducing among the receipts of cookery for the sick and convalescent many which medical opinion and practice in the present day have brought into comparative disuse. The receipts for making animal jellies are of this number. Formerly calf's foot jelly was administered as the prop of the life of a debilitated convalescent; now it is almost as universally rejected, as conveying little nourishment, or, if given, as the medium only for wine or other cordials, not as a restorative in itself.

5414. On the receipts for *caudle* some remarks must also be made. This was formerly considered as indispensable in the lying-in room. Now it is seldom or ever admitted into it. Of such cases the treatment of the present day forbids all heating diet for at least the first fortnight, and by that time, the necessity for liquid food no longer existing in the same degree as at first, the patient, in all general cases, is beginning to return to her usual mode of living. Perhaps, in cases of extreme debility, this species of nourishment may be requisite, and especially to patients among the laborious poor. The physician is often obliged to reduce his opulent patients, whose usual diet is full and stimulating; but he finds the opposite course must be pursued to restore those to health whose lives have been laborious and diet spare. Their systems, when brought down by sickness, generally stand in need of every prop that can be safely administered. In the use of caudle, it may be safely and properly given to the poor lying-in woman, while to the affluent it may be equally prejudicial. But, while there are cases in which it may be useful, it is requisite that the mode of preparing it should not be overlooked in a work intended for general reference.

5415. *Many receipts for simple beverages have been given* in Book VIII., Chap. IX. In a family, sickness is sometimes long absent, and when it does come, the variety of beverages with which it may be permitted to alleviate the thirst of an invalid is either forgotten or unkn wn; and as the memory of the nurse may not be able at the moment to suggest the requisite variety, an enumeration here may be useful. The most usual, toast and water, and barley water, have been described in page 693.

Sect. II.—SIMPLE BEVERAGES FOR THE SICK.

5416. *Lemon Water.*—Cut into an earthen tea-pot, or a covered jug, two or three slices of lemon, with one lump of sugar and a spoonful of capillaire. On these pour a pint of boiling water, and cover it closely for two or three hours, when it will form an agreeable beverage for the thirst of a feverish patient.

5417. *Apple Water.*—Slices of apple and a little lemon peel and sugar, put into hot water, make a pleasant drink.

5418. *Raspberry vinegar*, a dessert-spoonful of which, in a tumbler of cold water, is liked by some invalids.

5419. *Tamarinds* and hot water, when cool, may, in some cases, be given; but no acid drinks should be given to patients without the knowledge of their medical attendants.

5420. *Milk Whey.*—Steep in a cup of hot water, for four or five hours, a small piece of rennet, about an inch and a half square. Pour the water, not the skim itself, into two quarts of new milk. When the curd is come, pour it into a sieve or fine earthen colander, and press the whey gently out of it into a jug. This may be given either cool, or made the warmth of new milk, whichever a patient prefers.

5421. *White Wine Whey.*—Dilute half a pint of new milk with an equal quantity of hot water; boil both together, and, while boiling, pour in at the moment two wine-glasses of white wine. A curd will form, which, after boiling the mixture for two or three minutes longer, will settle at the bottom of the sauce-pan. The whey must be strained carefully from the curd; it should be perfectly clear. Sugar may be added to please the taste. *Warm white wine whey* promotes perspiration, and hence is useful in the commencement of some complaints; but taken cold it has a different effect, and often in cases of low fever it is an excellent beverage; also, in the early stages of convalescence, it is as safe and sufficient a stimulant as can be given.

5422. *Lemon and Vinegar Wheys.*—Instead of wine, pour into the boiling milk and water a table-spoonful of lemon juice, or of vinegar. The whey obtained in this manner, being less stimulating than that of white wine, is sometimes given to an invalid in preference.

5423. *Nitre Whey.*—Pour into the boiling milk and water a dessert-spoonful of the sweet spirit of nitre. Sweeten it, and let the patient take it as warm as it can be drank. Its use is that of promoting perspiration in a greater degree than is effected by white wine whey, without being equally heating.

Sect. III.—Gruels and Caudles.

5424. *Gruel*, the basis of *caudle*, as well as a valuable species of nourishment for invalids, may be made either with *oatmeal*, with *common groats*, or with the prepared *Embden groats*.

5425. *Oatmeal gruel* is made by putting about three ounces of meal into a basin, and mixing enough of cold water with it until it becomes of a smooth consistency, thicker than that of cream, and then by putting it into a sauce-pan, and adding to it a quart of water; it is then boiled for half an hour, during which time it must be stirred frequently, and afterward strained off from the remains of the oatmeal. Another way of mixing the oatmeal with the water is, to pour half a pint of cold water on the oatmeal, and, straining it off into the sauce-pan, to add another half pint, pouring that off also into the sauce-pan. By repeating this process, the oatmeal will be soon washed into the sauce-pan, when it must be boiled twenty minutes, or even more, and strained off for use.

5426. *Common Groat Gruel.*—Wash three ounces of common groats, and add to them two quarts of water; put the mixture into a well-tinned sauce-pan, and after it has boiled up, draw it to one side of the fire, and let it simmer until it be reduced to half the quantity. Stir it frequently, and strain it through a sieve when done.

Gruel soon becomes sour, hence it should be made in small quantities at a time. For an invalid, or for a child fed upon gruel, it should be made daily.

5427. *Caudles.*—A caudle is made of fine, smooth, yet thick groat gruel. While it is cooling it should be occasionally stirred with a spoon. When it is wanted, it should be warmed up in small quantities, with enough of white wine, lemon peel, and nutmeg to flavour it, and of sugar to sweeten it to the taste.

5428. *Ale Caudle.*—To a quart of thick groat gruel add a pint of home-brewed ale, some allspice, and sugar. Boil all together for the space of five or six minutes, then strain it, and put it in a cool place till wanted. This caudle is frequently made for poor country neighbours in their confinement. It is useful as a nourishment for them at that period, and sometimes prevents them from resorting to stronger and more stimulating liquors.

5429. *Flour Caudle.*—This is for those who stand in need of astringent food. Put into a pudding basin half a pound of flour; cover the basin, and set it in a kettle of boiling water. Keep it boiling for two hours; the flour will be converted into a hard ball enveloped with a brown crust, which must be removed. The flour is then grated and put into a jar for use; and it is formed into a caudle by rubbing a dessert-spoonful of it into five table-spoonfuls of the purest cold water that can be procured. Set over the fire to boil five table-spoonfuls of new milk, with two lumps of sugar; when the milk boils, pour the flour and water into it at that very moment. Stir the whole over a slow fire for twenty minutes; it is then ready for use. Made in this way, it forms a good food for young children.

5430. *Rice Caudle.*—Boil a quart of water; mix one table-spoonful of ground rice with *cold* water, and pour it into the boiling. Continue the boiling until the caudle thickens, stirring it all the time. When it begins to thicken, add to it a wine-glass of brandy, some grated lemon peel, sugar, and nutmeg. Boil it a little longer, until perfectly smooth, and then strain it into a basin. Without brandy or spice, but with the addition of milk, this caudle forms excellent food for very young children.

Sect. IV.—Milk Nourishment for Invalids.

5431. *Milk porridge* is sometimes made by adding milk to fine groat gruel. Another way is, to mix a table-spoonful of oatmeal in a basin with cold milk, and to pour it, when perfectly smooth, into a sauce-pan containing half a pint of boiling milk. If this does not thicken it sufficiently, it must be boiled a little longer.

5432. *Scotch Porridge.*—Stir oatmeal and water together, and let it settle. Pour off the water, and add fresh to it. This must remain till the next day, when the water is strained away from the oatmeal and boiled. Milk is added while the porridge is boiling. The milk must be in the proportion of two parts of milk to one of water.

5433. *Onion Porridge.*—Boil an onion, sliced, in water for half an hour; pour away the water, and add to the onions half a pint of new milk. Boil together the milk and onions for half an hour, and serve all together in a basin. This, taken at bedtime, inclines a patient to sleep and to perspire.

5434. *Ground Rice Milk.*—Rub a spoonful of ground rice very smooth in a little cold milk; add to it three half pints of milk, some cinnamon, lemon peel, and nutmegs; boil all together for a quarter of an hour. Sweeten to the taste.

5435. *Sago Milk.*—Wash in cold milk a table-spoonful of sago, pouring off the milk, but adding to the sago a quart of new milk. Let both boil slowly together till reduced to a pint. Cinnamon may be added if required; but neither sugar nor spice is usually added to this food.

5436. *Arrow-root and Milk.*—Mix smooth, with a very little cold milk, one dessert-spoonful of arrow-root. Boil half a pint of new milk, and the moment it rises to the boiling point stir in gently the arrow-root and cold milk. It should be very thick when first made, or, on becoming cool, it will be too thin. If it does not thicken sufficiently at first, it must be boiled until it does thicken. But when milk and arrow-root are boiled together, it is supposed that it becomes of a more astringent nature than it is desirable it should be for invalids, generally speaking.

Sect. V.—meat and vegetable teas.

5437. *Beef tea* should not be made like common gravy or broth, but by a process which will prevent the fat from mingling with it. Cut half a pound of nice gravy meat into thin slices, and lay them in a hollow dish, pouring over them a pint and a half of boiling water; cover the dish, and place it near the fire for half an hour; remove it into a sauce-pan, and boil it for ten minutes over a quick fire; remove the scum which has risen in boiling; let it stand covered for ten minutes longer; strain off, and season it with salt only. Beef tea thus made is a light and useful nourishment to those whose stomachs are weak and irritable. It will serve also for the food of young children; and some persons habitually sick in a morning have found it useful as a breakfast.

5438. *Veal tea* is made in the same way, and in the same proportions of meat and water as beef tea. It is useful in the same cases as those in which beef tea is given.

5439. *Chicken Tea.*—Cut into small pieces a chicken, skin it very carefully, as well as any fat which may be visible. Boil it for twenty minutes in a quart of water; pour the broth away from the meat before it gets cold. This tea is generally given in cases of debility, after fevers, and at the commencement in an invalid of a state of convalescence.

5440. *Extract of Meat.*—When the pure juice of meat is to be given to invalids, it may be obtained by putting a little lean beef or mutton, cut small, into a glass bottle, corking it up and tying a bladder over the cork; the bottle must be put into hot water and boiled gently for an hour. On opening it, a small quantity of real gravy may be poured away from the meat.

5441. *Balm and Mint Teas.*—The young shoots of either of these aromatic plants make a pleasanter and more refreshing beverage for the fever patient than that made from the dried leaves. Boiling water must be poured on the leaves, and the tea-pot or vessel containing it must be covered over and set for an hour near a fire: during this process of infusion the aromatic properties of the leaves will be given to the water, making it a safe diluent in fever cases; and *mint tea*, of the fresh leaves, is sometimes useful in allaying nausea and vomiting.

5442. *Hyson Tea.*—A weak infusion of green tea, without milk or sugar, is a useful diluent in fevers, colds, and rheumatism.

Sect. VI.—egg nourishment.

5443. *Egg Mulled in Tea or Coffee.*—Beat the yolk of an egg very well in a tea or coffee cup; stir in it a little milk or cream; then pour in it, stirring it all the time, the hot coffee or tea, sufficient to fill the cup. If the hot liquid is poured in too hastily, or without stirring it at the time, the egg will curdle, instead of uniting with the tea. Invalids are recommended to try this mixture for breakfast, as being light and nourishing, without being heating.

Eggs may be mulled in hot water, or in hot wine, or in hot ale; the same precaution being taken in the mode of uniting them to any of these hot liquids which has been recommended above.

5444. *An Egg Draught for a Convalescent.*—Beat the yolk of a fresh laid egg, and mix with it a quarter of a pint of new milk previously warmed over the fire; add to this a spoonful of capillaire, one also of rose water, and a grate of nutmeg.

Sect. VII.—panadas.

5445. *Meat Panada.*—Take the meat of a chicken previously cooked, or the inside of a sirloin of beef, or of a loin of mutton, whichever is recommended by the medical attendant, mince it small, and pound it till it will pass through a sieve, when mixed with broth or hot water, which will be, according to the state of the patient, more or less rich and nourishing: unless ordered, no other seasoning than a sprinkling of salt should be added. When the panada is prepared, it should be put in an earthen vessel, and placed in a cool situation. A little of it, taken out as it is wanted, should be warmed up in a little panakin. It must be stirred all the time it is on the fire, and served with delicate thin sippets of bread.

5446. *Bread Panada.*—Grate a tea-cupful of bread, and mix with it some beef or mutton gravy, beating the bread with a spoon till perfectly smooth. Then boil it till it thickens, stirring it all the time it is boiling.

5447. *Another Receipt for Bread Panada.*—Boil a glass of white wine and the same quantity of water together, adding a little sugar and lemon peel to it, nutmeg, if approved of; but spices are rarely desirable for invalids. Grate a cup of bread crumbs, and, when the wine and water boil, pour in the crumbs; stir them together, and boil very quickly until the mixture thickens; take it off the fire and pour it into a basin.

Bread panadas may be flavoured with the juice of fruits, such as lemon and orange sirup, &c. Remember always that the ingredients must be boiled together, or they will not form into a jelly.

Sect. VIII.—Puddings for Invalids.

5448. *Light Flour Pudding.*—Take a spoonful of fine flour, boil a tea-cupful of milk, and mix the flour very smoothly with it. Let it stand till cold, occasionally stirring it, to prevent the flour from settling at the bottom. When cold, add to it the yolk of an egg, well beaten, with a very small quantity of salt; tie it up very securely in a buttered tea-cup, or small pudding basin; plunge it into a sauce-pan of boiling water, and let it boil fast for half an hour. It should be just firm enough to stand when turned out of the basin.

5449. *Bread Pudding.*—Pour a cup of boiling milk on two table-spoonfuls of bread crumbs; when cold, add the yolk of a beaten egg to it, and boil in a basin for a quarter of an hour or twenty minutes. Cinnamon boiled in the milk, or a bruised bitter almond, together with lemon peel, may be employed as flavouring ingredients.

Arrow-root pudding is made by mixing a table-spoonful of it in cold milk, then pouring it into boiling milk. It must then be allowed to cool, when the yolk (well beaten) of an egg must be added, and the pudding must be put into a basin and boiled for ten minutes. All puddings for invalids having eggs in them should be boiled in preference to being baked. Baking is supposed to render eggs less easy of digestion than boiling.

5450. *Tapioca.*—This vegetable gelatin requires to be soaked very long in water, and afterward steeped in milk. In all other respects it is prepared like arrow-root, whether in the form of pudding or jelly.

Sect. IX.—Blanc-manges and Jellies for Invalids.

5451. *Rice Blanc-mange.*—Steep a table-spoonful of rice in half a pint of milk for seven or eight hours. If the milk dries up too much, more must be added, but it must be no more than sufficient to make the rice soft and moist. Any flavour, either of almonds, lemon peel, cinnamon, or nutmeg, may be added. When the rice is entirely pulped it must be put into a mould until cold, when it will turn out.

5452. *Isinglass Blanc-mange.*—An ounce of isinglass dissolved in a pint of boiling milk, and flavoured with bitter almonds, lemon peel, &c., if boiled for some time together, will form an agreeable, nutritious blanc-mange for a convalescent. When put into a mould it should be stirred occasionally until it begins to stiffen.

5453. *Savoury Meat Jellies for Convalescents.*—Take the bones and gristle of a knuckle of veal, with about a pound of the meat, the scrag end of a neck of mutton, half an ounce of isinglass, two blades of mace, a little salt, and a gallon of water. Boil gently (scumming very carefully) for five hours, or longer, if not reduced to about a quart. Do not put the isinglass and mace in till the scumming is done. Strain the jelly away from the ingredients, and when cold remove the fat from the surface. A stiff jelly is thus procured, which is agreeable if eaten cold; if warm, milk or wine may be mixed with it.

5454. *Another savoury Meat Jelly.*—Chop a knuckle of veal and a scrag of mutton, so that they may be placed one bone on another. Scrape and slice three carrots and two turnips, cut small a head of celery, butter slightly the bottom of a stone jar or a well-tinned sauce-pan. Lay in layers the meat and vegetables alternately, packing them closely together. Sprinkle over each a very little salt; cover the jar closely, and put it into a slow oven for half an hour, then open it and pour in as much hot water as will cover the ingredients. Cover the jar again closely, quicken the oven, and let it remain in it for five hours. Strain the liquor away from the meat and vegetables; when cold, remove the fat from the surface, and the sediment from the bottom. The jelly will then be ready for use. It will not keep long unless boiled up again about the second day.

5455. *Dr. Denman's Receipt for Gloucester Jelly.*—Dissolve one ounce of isinglass in half a pint of spring water; bruise, and add to the jelly, half an ounce of nutmeg and half an ounce of cinnamon; let all simmer in a new pipkin until the isinglass be perfectly dissolved; strain it off, and set it in a cool place to jelly; cut it in pieces, add a bottle of good old port, and the spice before boiled in it; sweeten it to the taste, and let it simmer until the jelly be again dissolved, when it may be bottled and kept for use. Half a wine-glass may be taken at bedtime. Observe, the wine must not be simmered in a sauce-pan, but in an earthen jar, put into a sauce-pan of cold water, and set over the fire to warm gradually.

5456. *Another Wine Jelly.*—One quart of sherry, in which dissolve two ounces of isinglass (picked and broken into small pieces), two ounces of white sugar-candy (pounded), one nutmeg grated, one pennyworth of gum Arabic, finely pounded. Put these ingredients together in an earthen jar, and the jar into a vessel of water, which must be suffered to warm gradually. When the isinglass and gum Arabic are dissolved, strain the whole into a basin or deep dish; keep it dry and cool, and let the invalid have a piece about the size of a nutmeg a few times in the day.

5457. It must be here remarked that these strengthening wine jellies are very much in disuse; isinglass, one of the animal gelatins, is no longer regarded as nutritious, and strong foreign wines are much more rarely administered in the different stages of convalescence than they were a few years ago.

5458. *Carrogeen, or Irish Moss Jelly.*—Wash and nicely pick an ounce of this moss; boil it in a pint and a half of water for twenty minutes; strain it, and pour it into a basin to jelly. For invalids, and for children when weaned, it is an excellent food, mixed with warm milk.

5459. *Arrow-root Jelly.*—Put into a sauce-pan and boil together half a pint of water and one glass of sherry, or a table-spoonful of brandy, a little grated nutmeg, and fine sugar. When boiling, mix with them, by degrees, a dessert-spoonful of arrow-root, previously rubbed smooth in a table-spoonful of cold water; boil all together for three minutes, and then pour it into glasses or small cups. If the invalid is not allowed to take wine, the jelly may be flavoured with lemon or orange juice, or with the juice of any of the fruits which may be in season.

5460. *Tapioca Jelly.*—Wash a table-spoonful of large tapioca in two or three waters; then let it soak in fresh water for five or six hours; in the same water simmer it till it becomes a clear jelly; and to flavour it and render it palatable, any of the ingredients may be added to it with which arrow-root jelly is flavoured.

5461. *Fruit Jellies.*—Take the juice of three sweet oranges and of twelve Seville oranges, and boil it with its weight of sugar, and put it into jars or glasses for use. If required to be very firm, dissolved isinglass may be put into the quantity required at a time for use.

The juice of bottled damsons added to dissolved isinglass makes an agreeable change occasionally for invalids.

BOOK XVII.

ON THE VARIOUS TEXTILE FABRICS FOR CLOTHING AND FURNITURE.

CHAPTER I.

ON DRESS IN GENERAL; SPINNING AND WEAVING.

SECT. I.—GENERAL REMARKS.

5462. *Clothing, taken in its extended sense,* may be considered as an expensive, and, in every way, an interesting part of domestic economy. In the materials for dress we include not only all *cloths* and tissues used for male and female attire, together with the articles made from leather, from skins, and from furs, but also the ornamental parts of dress, as feathers, artificial flowers, and the multitude of decorative appendages comprehended under the term "jewelry." Some articles that enter into the composition of dress are of great intrinsic value; while others, though not costly in themselves, are attended with a very considerable expense from the frequency of change which the laws of fashion impose. Since this expenditure cannot be avoided, it is a matter deserving consideration how it may be most economically and properly regulated.

In this inquiry, attention should be directed rather to the *quality* than to the *price* of the materials, since cheapness, unless resulting from fair and open competition in trade, is a very equivocal criterion. Every merchantable commodity must yield a profit to the manufacturer, to the wholesale dealer, and to the retailer; and in the regular course of trade, no portion of these profits can be abandoned without a prospect of compensation in deteriorating the article. The substitution of machinery for manual labour may, from time to time, occasion a reduction of the original cost price, of which the public rarely fails to reap the benefit; but this causes very little change in the gradation of profits, which are small if the demand be constant, and considerable if the article be costly and slow of sale.

Here it will, perhaps, be objected that rules for purchasing the materials for manufactured goods are now rendered almost unnecessary, by the changes that have taken place in the mode of supplying the principal articles of fashionable attire. The tailor, invading the province of the woollen-draper, undertakes to furnish complete suits by contract at a stipulated price; and the milliner, by a similar extension of her original calling, supplies her customers with every novelty of the season in a finished state. Yet, even in these cases, it may be useful to possess such a knowledge of the qualities of goods as may enable the purchaser to discover whether an inferior article has been substituted for that which was ordered, or whether the terms of the contract have been strictly fulfilled. The same power of discrimination is highly useful in the selection of those fabrics which are still purchased by the piece or yard, and made up at home, or under the express direction of the purchaser; and it often happens that a mere hint, or a technical expression casually uttered, will frustrate many of those stratagems of trade which some dealers think themselves justified in practising on the unwary. In all transactions relating either to the purchase or disposal of jewelry, in particular, a certain degree of skill and experience is indispensably necessary, and may be acquired without much difficulty.

5463. *It is foreign to our object to enter into the history of dress or costume,* or to point out the numerous fashions that have existed among us of late; the prevailing taste of the day, in this respect, is well understood; but the forms of dress being continually subject to the arbitrary rule of fashion, are seldom permitted to be regulated by individual feeling of convenience or utility. There are, however, some philosophical or physical principles established respecting clothing that are permanent, and it is to these that we wish to direct the reader's attention.

5464. *The usual temperature of the body* is about 98°; and its warmth is derived from the decomposition of the air taken in by respiration, which is necessary to supply the continual loss of heat we are liable to. Clothing checks or prevents, in some degree, this loss; and it follows, of course, that the materials which are the best non-conductors form the warmest clothing. But there are several other circumstances to be taken into consideration in making choice of the materials most suitable for this purpose. The skin, by its structure, performs the functions of regulating the temperature; by perspiration through its pores the excess of heat is carried off; and hence, when this function is deranged, and the insensible perspiration obstructed, fever is the consequence. In addition to this use, the pores of the skin serve as an outlet for getting rid of matters no longer necessary in the animal economy, and which, if retained, would prove injurious. Besides this excretory function, the skin has likewise an absorbing power, by which it takes up matters in contact with it; and we may also observe that it is abundantly supplied with minute nerves, which are the source of feeling, and which demand a certain degree of warmth to preserve their vital action. From these facts, it is easy to deduce, that clothing should be of such a nature as not to impede the necessary escape of perspirable matter, but to suffer it to pass through its texture; that it should be of such a non-conducting quality as to confine the heat generated by the blood sufficiently to preserve the activity of the nervous system; and that, by its lightness, softness, and pliancy, it should permit the free motion of the limbs.

5465. *Our artificial clothing is chiefly obtained from four principal raw materials,* wool, flax, cotton, and silk. The fleece of the sheep was probably one of the first substances made into cloth; and that animal is supposed to have come originally from the mountainous regions of Asia; flax appears to have been indigenous in Egypt, and probably in other countries; the silk-worm was given to China; and the cotton plant to India and America. Wool, as the warmest material, is produced only in cold countries, while cotton, best calculated for a tropical climate, is only there found native.

Thus, while the bounty of the Creator has furnished these in inexhaustible abundance, his wisdom has given them in such forms as to exercise the industry and ingenuity of man in applying them to useful purposes, and in such situations as strongly to encourage the intercourse between different nations.

5466. *The earliest dresses of mankind* probably consisted of the skins of animals; and it appears that these were employed as clothing long after the invention of the art of weaving. Thus, Hercules is said to have worn the skin of a lion which he had slain; Virgil, when he describes Æneas as about to take his departure from Troy, represents him as having his outer vest formed of a similar material; and he depicts Acestes as formidably clad in the skin of a Libyan bear. The sacred writings also contain frequent mention of skins as furnishing some parts of dress. The same material is now used by some of the uncivilized nations of America; and, when prepared by the art of the tanner, skins are still partially employed as dress in various parts of Europe. But skins are liable to the objection we have mentioned, of being impervious to the cutaneous exhalations, although this property, by which they confine the heat, renders them valuable in those extreme northern countries where the warmth of clothing is paramount to every other consideration. In temperate and warmer climates, the rigidity of skins, the difficulty of cleaning them when soiled, and other circumstances, have caused them to give way to the use of tissues woven of threads made from various fibres, the superiority of which was recognised at an early period, and gave rise to the arts of spinning and weaving.

5467. *Wool, upon the whole, has several advantages over other materials for clothing.* From its filamentous texture and elasticity, it may be made into cloths of great warmth, yet very light. It is not so easily wetted as others; by its felting property it may be rendered extremely compact, and yet may be woven into fine stuffs that almost rival in thinness those of cotton, but having more warmth, and being less inflammable. In former times, in Europe generally, woollen, and not linen, was worn next the skin; and various opinions have been entertained with respect to each practice. The arguments in favour of flannel are that, from its loose texture, it is a better non-conductor of heat than a more compact substance, and hence its warmth, by preventing the heat of our bodies from escaping, and being thus more capable of preserving them in an equality of temperature, and protecting them against sudden external changes.

Its rough and uneven surface, likewise, gives, in every movement of the body in labour or in exercise, a gentle stimulus, in consequence of the friction, to the cutaneous vessels and nerves, which assists their action and maintains their functions. From its porous texture, it also absorbs the cutaneous exhalations to a greater degree than any other material in common use. On the other hand, it is thought to be more debilitating in warm weather, by increasing perspiration, and is considered to be less cleanly than linen, by not requiring change so often: the last argument, however, is nullified by changing it as frequently. It is, however, generally agreed that flannel is advantageous if employed properly; and the cases where it is found most beneficial are where the body is exposed to frequent changes of temperature, and for persons advanced in years, where the circulation has become more feeble, and is, consequently, more easily checked. The finer the wool, the warmer it is, and the less it irritates the skin. Some, instead of wearing flannel next the skin all the year round, leave it off in the summer; but, although this would seem most conformable to reason, it is said that the danger of change is greater than the inconvenience of continuing its use in the short period of warm weather which we generally have in our variable climate. Workmen and labourers, when engaged in operations that excite much perspiration, are particularly benefited by wearing woollen dresses next the skin; and its efficacy, as a preservative from disease, is not confined to cold climates; for several medical writers, particularly Sir George Bullingal, in his "Lectures on Military Surgery," speak of its advantages; and Sir James Macgregor, Captain Murray, and others, have found from experience that soldiers and sailors derive great benefit from it in the West Indies and other warm parts of the world, in consequence of its checking the bad effects of the variations of temperature.

Woollen clothing has been proved to be extremely serviceable in preserving those who are unavoidably exposed to the action of malaria and epidemic influences. A late writer on the malaria of Rome strongly advocates this opinion, and expresses his conviction that the ancient Romans suffered less from it chiefly because they were always enveloped in warm woollen dresses. This opinion, he says, is justified by the observation that, since the period at which the use of woollen clothing in that country came again into vogue, intermittent fevers have very sensibly diminished in Rome. Even in the warmest weather the shepherds in the environs of that city are now clothed in sheep skins.

5468. *The use of linen for inner garments* has been favourable to cleanliness, and hence it has become very general through modern Europe. It requires comparatively little trouble to keep it clean, and its whiteness enables us easily to see when it is soiled, while its cheapness renders it easy to be renewed. Linen does not absorb so much of the perspirable matter as woollen, being sooner saturated, and consequently leaving the pores of the skin partially clogged up; on which account it ought to be frequently changed. It feels colder to the skin than flannel; and that arises from the density of the fibres of flax, which renders it a good conductor of heat, consequently robbing us of a portion rapidly when just put on. From the experiments of Count Rumford (*Phil. Papers*, i., 267), it appears that linen does not attract dampness so readily as wool, hair, or other animal substances; nevertheless, when it is damp it is more prejudicial than these, and therefore requires good airing before it is worn.

5469. *Cotton cloth*, though differing little in appearance from linen, does not agree with it in all its properties. Calico, in its powers of conducting heat, holding a middling rank between linen and flannel, has been for some years gradually superseding the use of the former for shirts and other garments worn next the skin; but it is by no means a succedaneum for flannel. It is not so durable as linen, though its cheapness is a great recommendation.

5470. *Silk*, though warm and soft, is better calculated for outer than for inner garments, and for purposes of elegance and show than of mere utility. As a warm covering, however, it has some valuable qualities.

5471. *Furs* excel every other material for warmth; but with us they are chiefly used for appearance; wool, in general, answering every purpose where great warmth is required.

5472. *Although it is proper to adapt the warmth of our clothing to the season of the year*, yet change in this respect should be made with caution. Very light clothing during the summer months exposes the body to the effects of those sudden changes of weather which we experience in our climate. It is safer to wear the same clothing nearly all the year, than to make frequent and sudden changes: exercise, under too warm a dress, occasions violent perspiration, the effects of which are often dangerous. It is remarkable that, in some countries, the custom differs materially from ours respecting clothing. We dress, in general, somewhat warmer when we go out than when we sit in doors; the Turks, who seldom have fires in their apartments, keep themselves comfortable within doors by using warmer clothing than when they go out, considering the exercise of moving about as a source of warmth. The Chinese of rank, it is said, practise the same mode; putting on an additional garment in the house, which they throw off as the sun ascends to the meridian, and resuming it in the cold of the evening.

The young and vigorous require less clothing than the old and infirm, and can better resist changes in the weather; but it is said, and perhaps truly, that young people take too little care of their health with respect to heat and cold, and old people sometimes too much.

5473. *The choice of colours in dress*, though generally a matter of fashion, or mere caprice, has some foundation in physical principles. Certain colours naturally suit each other, or harmonize together. Of all colours, black reflects least, and absorbs more of the heat that strikes upon it than any other colour, which warmth it communicates to the body; but, on the other hand, it radiates more than any other colour, and of course gives out more of the heat which it receives from the skin, producing a counteracting effect. On the contrary, white is the least warmed by the sun, but is more effectual in confining the heat of the body by its imperfect radiation. The difference between them with respect to warmth is, that black clothes are the hottest when the sun is most powerful, and white the warmest when the sun has least power; while white is coolest in summer, and black the coldest in winter.

5474. *In the following account of the clothing manufactures* we shall not attempt going into all the minute details respecting them, but only say what is necessary to give an idea of their general history, and to point out the proper distinctions between the several fabrics. We shall class them according to the natural substances of which they are composed; and we shall preface our account with the processes of spinning and weaving.

Sect. II.—spinning.

5475. *The art of spinning yarn, or thread, is of great antiquity,* and must have preceded that of weaving cloth. The most ancient and the simplest mode of spinning is by the distaff and spindle; the distaff is nothing more than a stick that the spinner fixes in his girdle, supporting it with his left hand; round the top of this is the material to be spun, which, after being properly prepared, is lapped round, so that a few fibres at a time may be drawn off from it with the thumb and finger of the right hand, to form the thread. The spindle is a small piece of hard wood, made round and pointed at one end, to which the fibres to be twisted are attached; this being put into a twirling motion by the hand, twists these fibres together as fast as they are drawn out by the fingers, in an even manner. The motion of the spindle is constantly kept up by striking it as often as the hand can be spared from the operation of guiding the thread, which, as it is twisted, is wound round the spindle till it forms a ball.

5476. This very simple mode of turning the spindle was, in some places, superseded by the use of a wheel and band employed for that purpose, which forms a machine called the *one-thread wheel;* this has been long used in India for spinning cotton, and in Europe for spinning flax, cotton, and wool. But the wheels for spinning must be adapted in some degree to the nature of the materials operated upon.

5477. Flax, owing to the great length and straightness of the fibres, has merely to be dressed so as to bring the fibres parallel to each other, though of different lengths, and thus they are drawn down by the fingers, and united together by the twist of a wheel. This length of the fibres gives the yarn a greater tenacity than that of cotton, while, at the same time, it is more difficult to form them into a very regular and fine thread, because the fibres themselves have no natural determinate size, this depending a good deal upon the processes by which they are split or divided. The structure of the fibres, also, being more smooth and glossy, and having no entanglement, they require to be made adhesive by moisture or wetting, which renders them more pliant and easier to twist together. The fibres of flax have much less elasticity than those of wool; the latter will stretch to from one fourth to one half more than their length before they give way, whereas the fibres of flax will not stretch above one twenty-fifth of their natural length.

5478. *The flax wheel* is turned by a treadle moved by the foot; a catgut cord goes from a groove in the rim of this wheel, and over the pulley of a spindle on which the thread is wound, and which is turned by the motion of the wheel. A bundle of flax, prepared, is fixed to an upright fastened to the frame of the wheel, from which the fibres are drawn by hand and led to the spindle, being regularly disposed upon it by an apparatus called a *flyer.* When this spindle or bobbin is full of thread, it is taken off and an empty one placed there to supply its place. The length of the fibres of flax permit several of them to be drawn down together to some little length, which are afterward twisted into a thread by the revolution of the spindle.

Wool and cotton require a very different treatment from flax in spinning. The fibres of these materials are short, and they must be carded and made into a roll before they can be drawn out into a fine and even thread fit for the loom. Most of the vegetable fibres, as flax and hemp, require to be moistened during the spinning, to render them more supple; but cotton, wool, and silk are spun in a dry state.

5479. *The wheel for spinning wool* for cloth also differs materially from that employed to spin flax. In the former (*fig.* 777) the spindle is made of iron, and placed horizontally on the end of a wooden frame standing upon legs. A wheel is supported upon the same stand, and a band goes over the wheel and the spindle, the revolving motion given to the former being thus communicated to the latter. The cardings of wool are made into soft, fleecy rolls of about twelve inches long and three quarters of an inch thick, and this roll or carding has, at first, one end fixed to the spindle, while with the left hand of the spinster it is drawn out into a loose, coarse thread called a *roving,* about the thickness of a quill; the wheel is turned with the right hand by means of a cord that passes to the spindle. The motion thus communicated to the carding twists it spirally; when twisted, it is wound upon the spindle; another carding is attached to the last, drawn out and twisted, and thus, by adding one roll to another, is formed a continued thread, or roving. These rovings are next spun into *yarn* fit for the

Fig. 777.

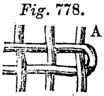
weaver by the same hand-wheel, and nearly in the same manner as the cardings were made into rovings. Worsted is spun in a different manner, and more resembling flax-spinning, from long wool prepared by the wool-comber.

5480. *Such were the spinning-wheels universally used in this country and on the Continent previous to the year* 1764, when, by a succession of inventions unparalleled in the history of the arts, spinning underwent a complete revolution, and was effected with an extraordinary degree of despatch by means of some of the most curious and complicated machinery ever devised by human ingenuity; in consequence of which, yarn is spun with an extraordinary degree of regularity, and of various degrees of fineness adapted to the different tissues for which they are destined, from the coarsest cloth to the finest cambric or lace. But as the great improvements in spinning by means of machines originated in the cotton manufacture, we shall reserve our account of them to the description of "Cotton Fabrics." Nevertheless, the spinning-wheel is a pleasing object in cottage scenery, and notwithstanding the superior cheapness of machine-made yarn, it is, perhaps, desirable that some employment should be reserved in a simple state, which may fill up the vacant hours of rural life, and offer some reward to humble industry; or which may be put into practice in places where complicated machinery cannot be obtained.

Sect. III.—weaving.

5481. *Woven cloth is always composed of two sets of threads*, or, as the weavers call them, *yarn*, crossing each other at right angles. One set extends the whole length of the web, or piece of cloth, and is called the *warp;* the other set runs from side to side of the web, or across the cloth, and is called the *woof* or *weft;* the latter is not a succession of different threads, but one continued thread through the whole piece of cloth; it passes alternately under and over each thread of the warp, until it arrives at the outside one, or edge of the web; it then passes round the edge, and returns back over and under each warp thread as before, but so that it now goes under those threads which it went over before, thus firmly knitting together the woven tissue. The outside yarn of the warp, round which the weft doubles, is called the *selvage* (*self-edge*), and cannot be unravelled without breaking the weft. This structure of cloth is easily seen by examining a piece of linen or calico with a magnifying glass (*fig.* 778, A), and may be observed on a large scale in matting, which is woven of coarse grass, or similar substances.

Fig. 778.



A

5482. *Indeed, some kind of matting made of the fibrous parts of plants*, as the stalk, such as the rushes and straws, was probably the first kind of cloth invented by rude and uncivilized nations; and the art of spinning threads from fine fibres was probably a refinement upon this, which led to the weaving of what we, at the present time, term cloth. Some nations are still ignorant of the art of weaving; for the cloth made in Otaheite, where it was first discovered by Captain Cook, was made by merely cementing vegetable fibres together, and was very analogous to our paper; and the Tartars make cloth by merely felting wool.

5483. *When the process of spinning threads* from the delicate and short fibres which animals and vegetables afford was discovered, the weaver was furnished with a material superior to any fibres in their simple state, and the foundation was laid of the art of producing woven cloth. When, and by whom, that discovery was made is not known; but it appears to have happened early in the history of mankind. The cultivation of flax was practised by the ancient Egyptians, and it is recorded that Pharaoh was arrayed in vestments of fine linen. The Hindoos have made cotton cloth from time immemorial, and the Hebrews were also in possession of the arts of weaving, dyeing, and embroidery.

5484. *Weaving was introduced into Britain by the Romans*, along with other arts of civilization; but, from various causes, so little did our British ancestors profit by the example which had been thus set, that for several ages a great part of their wool was exported to the Low Countries, where weaving had been successfully practised, and brought back in the form of cloth. At so late a period as 1331, this art was so little understood in England, that the arrival of two weavers from Brabant is recorded in the chronicles among the important events of that time. But it was the religious persecution under the Duke of Alva, and the revocation of the Edict of Nantes, that occasioned a great number of Flemish weavers to take refuge and settle in this country.

Weaving is performed by the aid of a machine called a *loom*, and the simplest kind, or common looms, vary but little as to their general structure, whatever may be the nature of the fabric they are intended to make, the chief difference in those for weaving silk or wool consisting in the greater stability and strength of the latter, on account of the greater coarseness and elasticity of the fibres and the thickness of the cloth woven. Great improvements have been made of late in looms, particularly in weaving cottons, muslins, and silks; nevertheless, the old-fashioned common loom is still employed, particularly in Spitalfields and other places, for weaving plain silks.

5485. *The first operation in weaving* is to extend the warp yarn in parallel lines. This

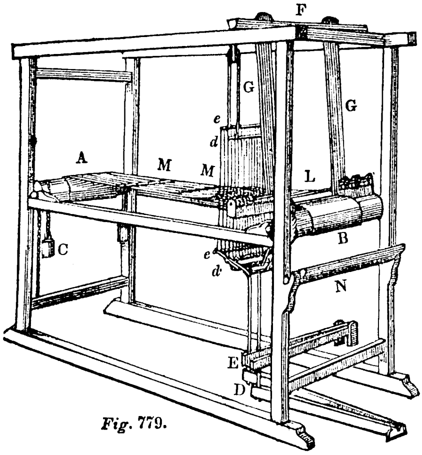


Fig. 779.

is effected by means of a contrivance called a *warp-mill;* and it is then rolled carefully round a thick roller in the loom (*fig.* 779, A), called the *warp-beam*, having a weight, C, suspended from it to keep the warp stretched. From this the warp, M M, forming the length of the piece, is stretched to another roller in the loom, called the *cloth-beam*, B, because the cloth is wound upon it when completed. Every thread of the warp between the two beams passes through loops in two sets of vertical threads, stretched in frames called *hiddles, d d* and *e e*, which are connected by strings at the bottom with two treadles, D and E, to be pressed up and down by the weaver's feet. The use of these treadles is to separate the threads of the warp by raising and depressing each thread alternately, and thus make way for the weft to pass through, the two treadles being so united by a rope and pulley that the depression of one must cause the raising of the other. The weft is driven from one side to the other through this space, called the *shed*, by means of a *shuttle* thrown from the hand. The shuttle, *fig.* 780, is a small box pointed at both ends, and contains a small bobbin of cane, called the *quill*, having the weft wound on, and which runs off as the shuttle is thrown. No sooner is a thread of weft thrown by the motion of the shuttle than it is driven up close to the last thread of weft by the blow of a comb-like apparatus called a *batten* (L, *fig.* 779), which consists of a long, narrow frame, with a number of slit pieces of reed, cane, or wires arranged perpendicularly, and so close that every thread of the weft passes through two of them: this batten is suspended in a horizontal position by two vertical laths, which are moveable like a pendulum, from a centre of motion at the top of the loom, F. The weaver, placed on the seat, N, lays hold of this batten, and, by pulling it towards him forcibly, he strikes the last-thrown thread of weft up to the cloth that is forming. When a certain number of threads of the weft are thus thrown by the shuttle, and brought up close by the batten and reed, so much cloth is made, and the cloth-beam is turned round to wind it up; this beam is prevented from going back by a ratchet wheel and click fixed on the end. Thus the operation in working the loom for weaving plain cloth consists of three simple movements: 1, opening the thread, or separating the threads of the warp alternately to admit the shuttle, which is effected by pressing the treadles that move the heddles; 2, throwing the shuttle by hand to form the weft; 3, pulling the batten and reed to strike home the weft, and again pushing it back to the heddles.

Fig. 780.

The fineness, or, rather, the closeness of texture in cloth depends upon the number of laths or *dents* which the reed contains within a given space, and which, of course, determine the number of threads of warp in the same space. The yarn of the weft is always somewhat finer than that of the warp, and the number of shoots of it in a given space must consequently always exceed the number of threads of warp in a similar space; that is to say, a square inch of cloth must contain a greater number of threads of weft than of warp.

5486. *The perfection of weaving depends* very much upon stretching the warp exactly parallel, and, likewise, on rolling them with great regularity upon the yarn-beam. It is necessary, also, that the weaver should exert the same force in every stroke of the reed frame, in order to make every part of the cloth equally compact.

Previous to warping, the yarn must be prepared by sizing or starching, called *dressing*, in order to cement all the loose fibres, and thus render it smooth, firm, and strong; and the weaver suspends his operation from time to time, in order to apply the dressing to his warp. The weft of muslins and thin cotton goods are generally woven into the cloth in a wet state, by which the fibres of the cotton are rendered smooth and parallel, the effect of which is similar to dressing the warp. The operations of hand-loom weaving are simple and soon learned, but it requires much practice to perform these with dexterity.

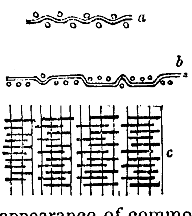
The great demand for cottons occasioned the power of water and of steam to be applied to the working of looms, which hence are termed *power-looms.* These perform the work with more expedition, economy, and accuracy than the common hand-looms, and threaten, at no distant period, the almost total extinction of that machine, a circumstance which has brought great distress upon many of the hand-loom weavers. Power-looms, worked without manual labour, were first tried by Vaucausin, 1747; but they were neglected till the idea again occurred to the Rev. Edmund Cartwright, in 1784; and it is remarkable that, at the time when he made the invention, he was imperfectly acquainted with the mechanic arts. After having expended between thirty and forty thousand pounds, he was unable to make his speculation profitable; and, to compensate him in some degree for his loss, Parliament granted him ten thousand pounds. Mr. Monteith was more successful, and in 1798 first applied the power-loom advantageously to the weaving of cottons. Various other looms of this kind have since been made, which answer completely for almost all the varieties of cotton fabrics, except delicate muslins. The steam-looms are chiefly employed in weaving printing cloth and shirtings; but they also weave thicksets, fancy cords, dimities, cambrics, and quiltings, together with silks, worsteds, and fine woollen or broad-cloth.

5487. *Plain weaving* is when the warp and weft intersect each other in regular order, so as to produce a uniform surface, as in plain linen or calico.

5488. *Figure-weaving is the producing of figures or patterns in cloth* by employing threads either of different colours or of different texture in the warp or weft. In weaving, the threads must be so disposed that some colours will be concealed and kept back, while others are placed in front; and they must occasionally change places, so as to show as much of each colour or texture as is requisite to make out the figure or pattern. Such changes of colour or appearance may be effected by three methods. First, differently-coloured threads, or threads of different sizes and substances, may be arranged in the warping, and require no change in the weaving: this will produce *stripes* in the direction of the piece; or the threads of the warp may be of one colour and those of the weft of another, which will produce a *shot pattern*. Secondly, several shuttles may contain threads of different colours and substances, and either of these may be used every time that a change of colour or appearance is required; this will produce *stripes in the weft*, or across the web. If this is combined with a variously-coloured warp, it will make *checkered* and *spotted* patterns of great variety. The third method consists in employing a number of heddle leaves instead of two only, each heddle having a certain portion of the warp passing through it, and provided with a treadle. When this treadle is pressed down, only a certain portion of yarns which belong to its heddle will be drawn up, and the rest will be depressed; consequently, when the weft is thrown, all those yarns which are drawn up will appear on the front or top of the cloth; but in the intervals between them the weft must appear over those warp threads which are depressed. The number of threads which are thus brought up may be varied as often as the weaver chooses to press his foot upon a different treadle, and in this manner the pattern is produced. By combining all these methods together, the most complicated patterns can be woven.

Tweeled or twilled cloth is a description of figure-weaving depending upon the arrangement of threads that compose the warp and the weft. These arrangements are very numerous, producing so many varieties of twilled fabrics, comprising satin, bombasin, kerseymere, diaper, damask, &c.; but it would be impossible, in a work like the present, to convey a clear idea of every variety. We shall confine ourselves, therefore, to a description of the general principle of this kind of weaving. We have stated above, that, on examining a piece of plain cloth, it will be seen that every thread of the weft passes alternately over and under every thread of the warp, as shown in the wood-cut, *fig.* 781, at *a*, where the little circles represent the warp, and the wavy line the weft. In twilled cloth the case is different; instead of the weft passing under and over each thread of the warp, it passes under one, and goes over more than one, sometimes two, three, four, or five, as *b*, according to the kind of twill or pattern. Instead, therefore, of the reticulated appearance of common calico, twilled cloth exhibits some of the threads passing along over several before disappearing; and *c* represents the surface of such cloth. When twilled cloth is composed of silk, it is called satin; when of cotton, fustian or jean; when it is composed of woollen, it is called serge, or kerseymere; and in linen it is distinguished by various names. It is easy to see how a great variety of figures, consisting of sprigs, flowers, or spots, may be produced by varying the mode in which the weft intersects the warp; and, in order that the weaver may clearly understand the intended texture of his piece, all the threads are drawn on paper before he begins, in a manner peculiar to themselves. Cloths may be twilled on one side or on both sides, as shalloon; and they may be made, by various dispositions of the loom, to exhibit the different stripes and figures seen in dimity, diaper, and damask.

Fig. 781.



5489. *Pile-weaving* is that by which velvets, various fustians, such as velveteens, corduroys, &c., are formed. In these, besides the warp and weft, another series of threads are woven in and fixed in loops, which are afterward cut to form the pile of these fabrics.

5490. *The draw-loom* is employed where the most intricate figures in cloth are required. These machines are necessarily complicated, though very complete; and it is by them that figured and spotted muslins, damask, whether of silks or linen, and even many carpets, are now woven. Those for damasks are the most curious, and their productions have justly excited the highest admiration. The most perfect loom of this kind was the invention of M. Jacquard, a practical weaver at Lyons; and the machine continues to bear his name. It has now superseded all other looms for figure-weaving, the skill and labour required being so much reduced by it, that they are little more than is required for plain weaving. It is lamentable to learn that this admirable invention did not benefit its author, who experienced the most bitter annoyances from his fellow-artisans.

5491. *Ribands* are woven in a manner analogous to cloth; but the looms are sometimes so constructed that upward of fourteen ribands may be woven at once.

5492. *Stocking-weaving* is of a different kind, and will be described under "Stockings."

CHAPTER II.

WOOLLEN FABRICS FOR CLOTHING AND FURNITURE.

SECT. I.—HISTORICAL AND GENERAL REMARKS.

5493. The substances employed for clothing are so numerous, and the ways of preparing them so various, that there are few arts in which more sagacity has been displayed, or where the inventive powers of man have been called more into action. The sheep, in early times, supplied clothing to many nations of antiquity; but it would be found that skin with its wool was too heavy and rigid, and that the latter, when separated, might be converted into cloth that was more flexible, and admitted of being made of various degrees of warmth.

5494. It is known that woollen garments, as well as those of linen, were worn by the ancient Egyptians. These also formed almost exclusively the attire of the ancient Greeks and Romans, though but little is known concerning their manufacture. We learn, however, that these nations bestowed great pains in improving their breed of sheep, and gave high prices for select animals; also, that they made woollen fabrics of great fineness.

5495. We have mentioned that though England had been long famous for its wool, yet that the art of weaving it into cloth, except that of the coarsest kind, was little known previously to the year 1331; the higher classes had fine cloths, but these were chiefly of foreign manufacture.

Little mention is made of this branch of trade in England prior to the reign of Edward III., who, having married Philippa of Hainault, found means to bring over a considerable number of woollen manufacturers from the Low Countries. These Flemings settled in York, Kendal, Halifax, Manchester, Norwich, and also in the west of England; but we have few records of the progress of the manufacture till the time of Henry VIII., when it had grown into considerable importance. Another advance was made in consequence of refugee weavers, who fled from the Netherlands to England, to avoid the religious persecutions of the Duke of Alva. These Flemings were graciously received by Queen Elizabeth, and obtained liberty to settle at Norwich, Colchester, Sandwich, and other places. Notwithstanding this, the manufacture of cloth made greater progress, for a long time, among the neighbouring nations than among ourselves.

5496. About the reigns of Edward VI. and Queen Mary, some kinds of woollen cloths began to be exported in considerable quantities; mixed cloth, in particular, for which the west of England has ever since been celebrated. In 1770, the exports of woollen fabrics of different kinds amounted in value to four millions annually; and in 1833, according to Mr. M'Culloch, the value of woollen goods manufactured was twenty-one millions sterling, of which about six millions are exported.

5497. *The inventions of Arkwright* for the carding and spinning of cotton wool were soon modified to suit the wool of the sheep, and produced an entire revolution in the woollen and worsted trade. Since that time, instead of the hand-spinning, described in Chap. I., the mechanical powers of water and steam have been applied to drive machinery for that purpose, and the localities of the woollen manufacture have moved into those counties where water and coal are plentiful; also the permission to export, which was formerly refused, being granted, English cloth and other woollen goods find markets all over the world. The improvements made within twenty years in the quality of our best broad-cloths are very considerable, partly on account of superior machinery, and partly from the several processes being better understood.

SECT. II.—ON THE NATURE OF WOOL, AND THE VARIOUS KINDS OF IT.

5498. *Wool is a kind of soft hair* which grows upon the skins of several ruminating animals, particularly sheep, the lama, the Angora goat, and the goats of Thibet. The distinction between wool and hair is rather arbitrary than natural, consisting in the greater or less degrees of fineness, softness, and pliability of the fibres. When the fibres possess these properties so far as to admit of their being spun and woven into a texture sufficiently pliable to be used as an article of dress, they are called wool. Both coarse and fine fibres are often found on the same animal, one of which might be called hair, and the other wool: many of the asses, and even oxen, of this country have soft woolly tufts on some parts of their skins; and this is more the case with the oxen of Thibet and the asses of Chili. The fleeces of sheep vary much in the degree of fineness in different parts of the body.

5499. *Sheep's wool, in its present state, appears to have been in a great measure the product of cultivation;* for we know of no wild animal that resembles the wool-bearing sheep. The argali, from which all the varieties of sheep are supposed to be derived, is covered with short hair, at the bottom of which, close to the skin, there is a softer hair or wool. This is not peculiar to the argali: almost all quadrupeds inhabiting cold climates are covered in the same manner with a soft hair, which is protected by a coat of longer and coarser hair. By removal to a temperate climate, or when placed under the fostering care of man, secured from the inclemencies of the weather, and supplied regularly with food, the coarse, long hair falls off, the animal retaining only the softer and shorter hair or wool. On the contrary, European sheep removed to tropical climates, and much exposed to the heat, lose their soft fleece, which is succeeded by a covering of short hair.

The goat of Thibet, which produces the extremely fine wool of which the Cashmere shawls are made, lives near to the tropics; but the country, from its height above the sea, is extremely cold. Sheep, in exposed situations in Europe, often produce short, coarse hairs intermixed with the wool, which fall off and do not grow again when the animals are removed to a warmer situation and to a richer pasture. These facts are sufficient to prove the effects of cultivation on the fleece; and, probably, finer wool-bearing sheep have originally become so by long-continued attention to those circumstances which have been found by experience to affect the fineness of the fleece.

It is probable, however, that climate and food alone will not produce the finest wool, although it assists greatly; and it has been shown that this is most completely obtained by a careful selection of such sheep as produce the best fleeces, and breeding from them for a few generations, until a new race is established that becomes permanent. In this manner have been procured those peculiar breeds that are now famous for their wool.

5500. *Sheep's wool may therefore be considered as much an object of cultivation as any vegetable product;* and it is never found of good quality except in those countries which have been the seat of the arts, and where a considerable degree of civilization and refinement exists, or has formerly prevailed. Where the culture has been long neglected, the product is uniformly found to be deteriorated. In the flocks of Barbary and the adjoining states may be traced the offspring of a fine-woolled race of sheep, degenerated by utter neglect, in a climate naturally unfavourable to the production of fine wool. In Sicily and the southern parts of Italy the remains of the ancient Tarentine breed preserve to the present day a race of fine-woolled sheep greatly degenerated by neglect. In Portugal the fine-woolled sheep retain more of their original purity, though in a state of degeneracy. In Spain, where the growth of fine wool has never entirely ceased to be an object of attention, the race of fine-woolled sheep exists in a high degree of perfection.

5501. *Wool, like the hair of horses and cattle, completes its growth in a year, and then falls off,* to be succeeded by a fresh crop; but, instead of coming off partially, as hair does, it is shed, if left to itself, nearly all at once at a particular period, leaving the animal covered with a short coat of young wool. To prevent this, and consequently the loss of the wool, this is shorn off when it has come to its full growth, and before it detaches itself naturally; the whole together constituting what is called a *fleece.* The time for sheep-shearing is regulated by the climate and the weather. In the southern parts of England it is generally about the middle of June. If sheep are shorn in cold weather, they suffer considerably.

The wool *shorn* from the living animal is called *fleece wool,* and is superior to that which is *pulled* off from the slaughtered sheep by the fellmonger, and which is termed *skin wool,* or *felt wool:* this is distinguished by its being harsher, weaker, and less capable of taking a good dye. The quantity of the latter in a country like England, where so much animal food is consumed, is very considerable. It is frequently too short to be worked by itself, and is then mixed in with longer wools. The process by which the wool is separated from the skins has a tendency to make it hard, and to destroy or injure its felting or milling property; on which account short-skin wools are seldom used for the manufacture of cloth, but more generally for flannels, serges, and those kinds of goods which require little or no milling; on this account, its value is less than that of fleece wool. The longer kinds of felt wool are used for hosiery yarns, or for hand yarn for the warps of serges and other goods having a warp of combed and a woof of carded wool.

5502. *The length of the fibre of wool constitutes an important distinctive character.* Sheep's wool is divided by manufacturers into two sorts, *long* or *combing wool,* and *short* or *cloth-*

ing wool; and these differ from each other materially in the uses to which they are applied. It is usual to speak of the length of the *staple* of wool. By the staple is meant the separate locks into which the wool naturally divides on the skin, each lock consisting of a certain number of fibres, which, collectively, are called the staple.

5503. *Long* or *combing wool* may vary in length from three to eight or ten inches; it is prepared on a comb with long steel teeth, worked either by hand or by machinery, which open the fibres and arrange them longitudinally, like those of flax; thread is therefore spun from this wool in the same manner as from flax, but the fabrics made of it are not fit to be subjected to the process of felting. The longest kinds of wool are manufactured into *worsted* or hand yarns, employed in worsted pieces, such as waistcoats, carpets, bombazins, crapes, poplins, and the finer kinds of worsted goods. The shorter combing wools are principally used for hosiery, and are spun into soft worsted yarn.

5504. *Short-stapled wool* is the only kind employed for making cloth, hence it is sometimes called *clothing wool;* it varies in length from three to four inches; if longer, it requires to be cut or broken to render it fit for carding and spinning into woollen yarn, and the subsequent operation of felting. This wool is always carded upon an instrument with fine short teeth, by which the fibres are opened and spread in every direction. The principal qualities required in clothing wools are, the regular fineness of the hair or pile, its softness and tendency to felt, the soundness of the staple, and the whiteness of its colour.

5505. *The fineness of the fibre of wool* has ever been considered as an important quality since the manufacture of cloth has been so much improved. The degree of fineness may be ascertained by the microscope: the thickness of a hair of the best Spanish and Saxon wool is not more than $\frac{1}{1500}$th of an inch, and that of the finest native English is from $\frac{12}{1500}$ths to $\frac{13}{1500}$ths. But the comparative fineness is sufficiently estimated by the eye of the wool sorter or wool dealer, who, by long habit, can discern minute differences which are quite imperceptible to common observers, and scarcely appreciable by the microscope; a difference in the size of the fibres, too minute to be noticed by persons not experienced, may occasion a difference of forty per cent., or more, in the value of the wool.

Fine wool was formerly valued because a finer thread could be spun from it, and a thinner fabric made than from the coarser wools; but since recent improvements in machine spinning have been introduced, it has been found practicable to spin coarse wools to the same length as the finer wools were formerly spun to. It is well known, however, to cloth manufacturers that, whatever be the fineness of the yarn, unless the wool also be fine, it is impossible to make a fine, compact, and even cloth, in which the thread shall be covered with a thick, soft pile; nor would a thin cloth made from coarse wool have the same durability or appearance as one from fine wool of equal weight per yard.

5506. *The finest of all wools* is that from the goat of Thibet, of which the exquisite Cashmere shawls are made; the finest of European wools are from the Spanish Merino breed, to which the best Saxon sheep belong. For coarse goods, indeed, such as blankets, carpets, and cloths called *duffels*, raised with a hairy pile, a considerable degree of hardness or elasticity of the fibre is an advantage; but in all the finer articles of the woollen or worsted manufacture, the fineness and softness are of great value. In some fleeces from the fine-woolled sheep of England there is sometimes an intermixture of coarse hairs, which proves very detrimental to the wool. In the Merino and Saxon sheep the fleece is more regular, whatever be the degree of fineness, than on any of our sheep.

5507. *The fineness of the fleece varies in different parts of the animal.* The finest is upon the spine, from the neck to within six inches of the tail, including one third of the breadth of the back or saddle; the second quality covers the flanks, and extends from the thighs to the shoulders; the third covers the neck and rump; and the fourth lies upon the lower part of the neck and the breast, down to the feet, as also upon a part of the shoulders and the thighs, to the bottom of the hind quarters.

Wool is sorted with great care into the various degrees of fineness, by persons much practised in this process; and they generally separate English fleeces into eight or ten sorts in a single fleece, which receive different names, and are applicable to different fabrics.

5508. *The softness of fine wool* for cloths is next in importance to the fineness of the fibre, but is not dependant upon it. It consists in a peculiar feel, which approaches to that of silk or down, but in which the wool of European sheep is inferior to that of Eastern Asia, or to the wool of the vicuna or lama of Peru and Chili.

The softness of the Indian wool is far superior to that of the very softest of the Merino fleeces; and yarn from Indian wool fetches a much higher price, sometimes even three guineas per pound, not on account of the superior fineness of the thread, but for the softness of the wool. In European wools there are different degrees of this property, even where the fibre is equally fine. In our English wools, a similar difference exists between the wool of one district and that of another, and which is imparted to the cloths made from each.

5509. *Fine clothing wool depending chiefly upon the peculiar breed* of sheep, and less upon soil and climate, may be grown, by care and attention, in every country where sheep will subsist and thrive; but it is different with the long combing wool: to grow this in perfection, rich pastures seem requisite, and these cannot be obtained under a parching sun, in tropical climates, nor could the animal exist clothed with a heavy fleece. Under such circumstances, the long-woolled sheep become feverish and diseased, and only recover by casting the fleece, which is replaced by a coat of short hair. The luxuriant pastures in England, particularly in Lincolnshire and Leicestershire, and in the opposite coast of Flanders, seem more favourable to the growth of long wool for combing than any other countries, and the wool of these places is highly prized for the worsted manufacture.

5510. *Lamb's wool* is generally softer than that of the sheep of the same flock; and as it has the felting quality in a high degree, is much used in the hat manufacture. The wool of dead lamb skins, called skin-lamb's wool, possesses less of the felting property, and is employed for flannels and lamb's wool hosiery. In the northern parts of Europe the lambs of some of the breeds of sheep possess a fleece so delicately soft, that it constitutes a most valuable fur, being dressed on the skin, and used as a costly article of attire, especially for morning gowns, among wealthy Russians.

5511. *The natural colour of wool* is white, gray, or brownish black. It is probable that all sheep's wool was at first of a dark colour, and previously to the invention of dyeing, coloured wool would have a preference to white; but after the discovery of a method of communicating beautiful colours to the fleece, white wool would be preferred as the most favourable for receiving bright colours, and those sheep which had white fleeces would be selected to breed from. Dark brown or black woolled sheep are not uncommon in many parts of Europe, and coarse cloths are made of their wool in its natural colour.

5512. *Wool, in the state in which it is taken from the sheep,* is always mixed with a great deal of dirt and foulness of different kinds, and, in particular, is strongly imbued with a natural grease, which requires to be removed. This is effected by the wool comber, by means of washing and combing, after which the wool becomes soft, clean, and springy, and is brought into the state adapted for the making of worsted and the manufacture of woollen stuffs.

5513. *The grease or yolk of the fleece* is an oily, or, rather, a soapy substance secreted by the animal. It is found to consist of animal oil combined with a little potash, forming of itself a kind of soap; hence it serves to facilitate the scouring of wool by water alone. It is most abundant in those breeds that have the softest fleeces, as the Merino; and while the animal is living, it serves to keep the wool in a sound state, and improves its softness; but, although so beneficial to the wool while growing, it becomes injurious to it after it is shorn, and should be removed as soon as possible; otherwise it will produce a fermentation, and render the wool hard and brittle, particularly in hot weather. Sometimes the fleece is washed with cold water on the animals before shearing; but when it is thick, as in the Merino breed, it is washed after it is shorn, either with hot or cold water, the former being most effectual. Wool loses in weight by this process from thirty to forty-five per cent. A copious supply of the yolk is necessary to the healthy condition of the fleece, and in some flocks it is nearly equal in weight to the wool.

5514. *The practice of greasing the sheep* with a mixture of tar and butter, practised in Scotland and the north of England, to preserve them from the effects of moisture and the inclemency of the weather, has been supposed to be injurious to the wool; but Mr. Bakewell has shown that, when the proportion of tar is not too great, the wool is greatly improved by this process, as the unguent preserves the wool in a soft state during the heats of summer, besides defending the animals from insects and cutaneous diseases.

5515. *The long-woolled sheep of England* are of four breeds: the Dishley, or new Leicestershire; the Lincolnshire; that of Teeswater, and of Dartmoor. The Lincolnshire and Leicester breeds produce the longest staple, being often a foot in length. The average weight of their fleeces is from eight to ten pounds. For the general purposes of the worsted manufacturer their wool is unequalled.

5516. *Our short-woolled sheep* are principally the Dorsetshire, Herefordshire, and Southdown. The sheep pastured on the Cheviot Hills, in Cumberland, though not of the finest-woolled English breed, yield fleeces of great softness.

5517. It is a remarkable fact, stated by several persons who have written lately on our manufactures, that *although Britain was long famous for its wool,* which was formerly considered as the staple article of British exports, yet at present the native wool of this country is deemed by our manufacturers to be unfit for making superfine cloth, and is not, in fact, used here for this purpose, all our superfine cloths being made with foreign wool. Prior to 1824, some good English broad-cloths were made of wool from Sussex, Norfolk, Suffolk, and Hampshire; but it is said that since that time our wool has deteriorated somewhat in its quality, and Saxon wool chiefly is employed. The great fault of English wool for cloths is the length of the staple as well as the coarseness

5518. The following table exhibits the various breeds of sheep in this country, with the quality and quantity of wool produced by each:

Breed.	Horns.	Colour.	Quality of the Wool.	Weight of Fleece.
				Lbs.
Dishley	No horns.	White faces and legs.	Combing, or long wool.	8
Lincoln				11
Teeswater				9
Dartmoor				9
Exmoor	Horned.	Ditto.	Ditto.	6
Dorset	Small horns.	Ditto.	Carding, or fine short wool.	3½
Hereford	No horns.	Ditto.	Very fine short wool.	2
Southdown	Ditto.	Gray faces and legs.	Ditto.	2½
Norfolk	Large horns.	Black faces and legs.	Fine short wool.	2
Heath	Ditto.	Ditto.	Coarse long wool.	3½
Hardwick	No horns.	Speckled faces.	Short wool.	2
Cheviot	Ditto.	White faces and legs.	Fine short wool.	3
Dun-faced	Ditto.	Dun faces and legs.	Ditto.	1½
Shetland	Ditto.	Colours various.	Fine cottony wool.	1½
Romney Marsh	Ditto.	White faces and legs.	Long wool.	8
Spanish, or Merino	Males horned, Females sometimes without horns.	Ditto.	Short wool, very fine.	3½

5519. *Spanish Wool.*—The finest woolled sheep in Europe, the Spanish Merino, may be traced to the Tarentine sheep, introduced by the Romans into Spain. This breed is said to have come originally from Asia, where, in the ancient seats of luxury, the utmost pains had been bestowed upon these animals. In the Middle Ages, so far back as 1243, Spain was celebrated for its fine woollen cloth, with which it supplied the Italian states. The males of the Merino sheep have horns, and the females are without them. They are covered by a great thickness of wool, and appear almost enveloped in it, scarcely giving way to the pressure of the hands. The number of these sheep in Spain is estimated to be about 5,000,000, and they belong to various wealthy proprietors; yet they are united together into one great flock, called the *Mesta*, which travels over the kingdom under the guidance of certain persons appointed to take care of it, feeding upon various commons or uncultivated lands, passing the summer in the mountainous districts, and the winter in the plains. This breed was tried in England by George III., but has not succeeded to the extent expected, although it has, in many instances, improved the English breed of short wool sheep. Formerly all our finest wool came from Spain; but Spanish wool is now almost entirely superseded by the Saxon and Australian. The Spanish flocks have suffered much in consequence of the war.

5520. *Saxon wool*, now so much employed in this country, owes its great improvement to the late King of Saxony when elector; on account of the superiority of the Spanish Merino sheep, he introduced them into his dominions, where they seemed to succeed even better than in Spain. Previously to 1800, our average annual imports of wool did not much exceed 3,000,000 lbs., mostly brought from Spain; but such has been the increase of the Merino breed by the Saxon wool growers, that the annual importation of wool from Saxony amounts to above 25,000,000 lbs.

This fact has excited the emulation of the states contiguous to Saxony; and the inhabitants of Silesia, Bohemia, and Austria have improved their flocks by the Merino.

Saxon wool is usually four or five inches long, but, from its tenderness, it admits of being easily broken down by carding to the proper shortness for clothing and fulling, which is from two to three inches, and is by much preferable for making fine broadcloths, kerseymeres, pelisse cloths, shawls, and such fabrics as require fine yarn.

5521. *Shetland Wool.*—A breed of sheep exists in the Shetland Isles, remarkable for the fineness of its wool. The sheep are small, and mostly without horns: they are suffered to run wild, and are not even sheltered in winter. In the summer they are confined to the hills, but after the crops are removed they are allowed to range over the country; and when the ground is covered with snow, the animals come down to the shores, and feed upon sea-weeds. For fineness and softness the Shetland rivals even the Spanish wool, while, being at the same time of longer staple, it is employed for the best worsted manufactures, as stuffs, the finest stockings, &c. The fleece attached to the skin is occasionally employed as an excellent fur. This peculiar breed is called *beaver* sheep. The colour of the wool is various, white, gray, brown, and black; but the quantity of this wool is not considerable. Some of the same breed occurs in a few places in the Highlands.

5522. *Australian Wool.*—A new locality for fine wool has been found in Australia. The Spanish Merino sheep were carried to New South Wales and Van Diemen's Land, where the climate appears peculiarly well suited to them: they are multiplying prodigiously; the wool is of the first quality, and these countries promise, at no very distant period, to be the principal wool-growing places in the world. Already our imports from Australia exceed 4,000,000 lbs. per annum. It is said that no wool spins so well, in consequence of the length of its staple and its softness; it is also better for combing purposes than any other description, and is, at present, altogether consumed in the finest worsted goods; most of those beautiful and soft woollen fabrics which go by the name of Indianas, Merinoes, and Challis, and which make such display in the shops of our haberdashers, are manufactured from this fine Australian wool.

Sect. III.—Manufacture of cloths and other woollen fabrics.

5523. *The term cloth, in its general sense*, includes all kinds of stuffs woven or manufactured on the loom, whether their threads be of wool, hemp, flax, or cotton, or any other material; but it is more peculiarly applied to those which are made of woollen threads. These differ in appearance considerably from cotton cloth. In the latter, the threads are distinctly visible; but in a piece of new woollen cloth they are completely concealed by what is termed the *nap*, or *pile*, of the cloth, and it is only after the nap is worn off that they are discerned, when the cloth is said to be *threadbare*.

5524. *The manufacture of cloth requires, as we have stated, the short or carding wool*, the elasticity and contractility of which render the cloth susceptible of the peculiar treatment of the fulling, felting, and teaselling operations, to raise and regulate the nap, or pile; and the qualities which distinguish cloth from all other manufactures, and which render it peculiarly suitable for elegance and warmth in the clothes made of it, are the compactness and density it acquires from fulling. Cloths are either superfine, second, or coarse.

5525. *A description of the mode of making superfine cloth* may serve for the whole, that of the inferior sorts differing little, except in the coarse and less delicate modes of performing the same operations.

5526. *The first operation is to clean the wool thoroughly.* For this purpose, being taken out of the bale, it is first picked, to clear it from the pitch which adheres to it, and from other extraneous substances. It is then scoured, by boiling it in three parts water and one of urine, from which it is afterward taken out and rinsed in running water; or it is soaked in urine, and rinsed frequently with clean water: it is then fit to be committed to the dye-house. After dyeing, it is again washed and dried, and then beaten with rods, to free it from the loose dye-stuff; but this operation is now generally performed by a wool-mill, or, as it is called, a *willy*, which, by means of revolving spikes, opens up and clears from sandy and other loose impurities the matted fleeces supplied by the wool stapler.

5527. *The wool, thus prepared, is now spread loose on a floor, and olive oil*, in the proportion of three pounds to twenty pounds of wool, evenly sprinkled over it, and beat into it with very heavy rods, to facilitate the future carding operation. But previously to the proper carding, it is carried to the scribbling engine.

Scribbling is merely a loose species of carding the oiled wool. The scribbling engine is a machine composed of several wooden cylinders of various sizes, covered with teeth or wire of different degrees of fineness, and bent and hooked in opposite directions. These are combined in a strong wooden frame, and so fitted as just to touch and work against each other, as they swiftly revolve on being set in motion by a common handle, adapted to be turned either by men's labour, or any sort of mill-work. By passing through this engine, the locks of wool, which before were close and matted together, are drawn out, the fibres are separated, and they are formed into light flakes, called *lap*.

5528. *The carding engine* receives this lap, works it over again, and delivers it in a narrow band, or *sliver*, which is preparatory to the spinning. Carding opens up and separates completely the woolly filaments, and renders the fleece lighter, more homogeneous; it also occasionally disentangles the connexions of the fibres, and causes the broken filaments to cross each other in every possible direction. By this the texture of the wool is rendered more downy, and the filaments made more elastic, and disposed to lay hold of each other, and thus put into a condition more favourable for the fulling process. Before the invention of machines for carding, to produce the roll, or sliver, this process was performed by hand-cards, which were mentioned in the description of spinning wool; but it is now done much better by the machine.

5529. *The cardings are next taken, in the form of light and delicate round rolls, to the slubbing or roving machine*, by which the separate lengths delivered by the carding engine are joined together by children, called *pieceners*, and drawn out in a continuous spongy cord to six times their former length, giving them, at the same time, a slight twist to maintain their cohesion and uniformity, thus forming what is called a *slubbing* or *roving*, which is, in fact, a very loose soft thread, that is afterward to be completed and made into yarn by spinning. This latter operation, now performed so expeditiously by machinery, which only requires the attendance of boys, was formerly done by hand on a spinning-wheel, as we have mentioned. Of course, various ingenious contrivances are necessary to prevent so tender a substance as wool cardings to draw out without breaking. Rovings for warp yarn must be more twisted than for weft.

5530. *The wool slubbing or rovings are now spun into woollen yarn* of the requisite fineness, either by the spinning-jenny or the mule, machines more particularly noticed in our description of the Cotton Manufacture, Chap. IV., Sect. III., for which they were first invented. In the structure and mechanical properties of its filaments, short or carding wool resembles cotton very closely, and therefore it may be spun by machinery nearly similar.

The asperities on the surface of the filaments render the spinning of wool difficult. This is in a great measure removed by besmearing it with oil, by which the inequalities are filled up, or at least the asperities become less sensible. When the wool is made into cloth, it is necessary to remove the oil, which is done by the process of fulling.

For the weaving of cloth, see "Weaving," Chap. I., Sect. III. From the similarity of the materials, the weaving of woollen cloth is not very different from that of cotton. We may just observe that what is termed the *list* of cloth, which is a strip of different colour at the edges, consists of a few stronger threads than the rest, to afford a firm hold for the hooks in tentering, to be described.

In the state in which the cloth is woven, the fabric would be too open, and the threads too apparent, to suit with the taste of the time, or to be as soft and comfortable as is required for dress. To render it more compact, and to improve its appearance, it goes through the next process.

5531. *It is the milling and fulling* that give to cloth that compactness and density which distinguish it from all other woollen fabrics. By this operation, a cloth of forty yards long and one hundred inches wide is so shrunk up, and consequently thickened, as to be reduced to thirty yards long and sixty inches wide, which renders it of the proper substance and thickness of common superfine cloth. The cloth to be milled is first cleared, by scouring, from the oil with which it was imbued for the carding; and as fullers' earth is used, this operation is termed fulling. Previously to the milling, a liquor is sprinkled on it, made of fine soap dissolved in water, and it is then laid in the mill-trough, where it is pounded or stamped on by heavy flat wooden hammers moved by wheel-work. The property of being rendered thicker by compression is peculiar to woollen substances; if fabrics of silk or cotton were subjected to the same process, they would not, in any length of time, be rendered thicker or more compact by it.

Fig. 782.

This property depends upon the peculiar structure of the fibres of wool. These, when viewed through a microscope of great power, appear like a number of rings inserted into one another (*fig.* 782), the edges of a longitudinal section being serrated or marked like a saw. By this peculiar structure of the fibres, they are disposed to move in one direction more easily than in another; and during the violent agitation which the cloth undergoes in the mill-trough, being at every stroke of the mill-hammer strongly impelled together, they are driven into the closest possible contact, and at length hook into each other, drawing closer and closer as the process continues, till they become thus firmly and inextricably united: thus each thread, both of the warp and the woof, being so joined and compacted with those that are contiguous to it, the whole is formed into a dense substance, that is not liable, like other fabrics, when cut with shears, to unravel and become ragged at the edges. It is supposed by some that this property, called *felting*, which is best seen in hat making, gave rise to the earliest kind of woollen cloth, before spinning and weaving were invented; since the disposition of wool to mat together and unite into a very compact body could not escape notice. The Tartar tribes at this day make a cloth, or felt, for their tents, merely by spreading out the wool on the ground and causing it to felt together by treading it with warm water, and beating it; and very lately this process of making cloth by felting only has been revived in this country, and very thick woollen fabrics, for various purposes, are made without spinning and weaving, and by felting only.

This process is essential to the beauty and strength of woollen cloth, and it is observed that the softer wools felt in much less time than the harder, and form a closer pile on the surface of the cloth, on which account it is a common practice to mix a certain quantity of soft wool with the hard, to enable the former to felt with more facility. The elasticity of the filaments has also a considerable effect in promoting the felting, as it causes them to curl. The furs of the hare, the rabbit, and the beaver, being naturally straight, cannot be employed alone for felting till they have acquired a curling texture at their points, by the application of nitrate of mercury. It is scarcely necessary to mention that, as the cloth shrinks so much in the fulling mill, it must first be woven so much wider, to allow of this shrinkage.

5532. *Cloth thus milled to its proper thickness must next be scoured* with clean water till it is perfectly free from the soap; and in this process a preparation of fullers' earth and bullock's gall is found very serviceable, rendering the cloth, at the same time, soft and mellow. It is then stretched on the tenter frame, and left to dry in the open air.

5533. *The dressing of cloth* is another operation it has to go through, which consists in bringing a nap on it, by drawing out all the fibres of the wool that can possibly be brought to the surface, which is afterward shorn as close and even as it will admit of, without laying bare the threads of the fabrics. The nap is raised upon the cloth either by teasels or by wire cards. The natural teasels are the balls which contain the seed of a large thistle called *Dipsacus fullonum*, which is cultivated on purpose; the scales of these balls project on all sides, and terminate in sharp elastic points that turn downward like hooks. When these are used by hand, the heads of the thistles are cut off, and set close together in small wooden frames, forming a tool not unlike a curry-comb. It is worked by two men, who, holding the teasel frame by the handles, scrub the face of the cloth hung in a vertical position. The first time of dressing the cloth they wet it with water, and work it by strokes in the direction of the warp, and next in that of the weft so as to raise up all the loose fibres from the felt, and prepare it for shearing. In large manufactories this operation is performed in what is called a *gig-mill*, which originally consisted of a cylinder set close round with teasels, but now sometimes covered with brushes of fine wire instead of teasels.

5534. *The next operation is shearing or cropping the cloth.* The cloth being laid on the shearing boards, which are made of wooden planks covered with coarse cloth, and forming a kind of hand cushion, the wool thus raised is cut off by long heavy shears, which are pressed close to the cloth with leaden weights, and gradually slide forward at every motion or cut, till they have proceeded from one list to the other. Lately, an improved kind of shears, of French origin, is much used. The cloth is then returned, to be again scraped, rubbed, and brushed; and these operations are repeated every time with finer cards, or teasels, till the wool becomes sufficiently raised. Shearing by machinery was first introduced in 1802, and finishes cloth in a more perfect manner than shearing by hand.

5535. *The cloth is then taken to the rack*, on which, being fastened by the lists with small hooks or tenters, it is drawn or strained, until it be of an even width throughout, and it is then sheared again to complete the surface. All the little bits of straw or lint that may adhere to it are now picked out, and any holes that may be discovered carefully fine drawn. After the shearing, cloth is subjected to the brushing machine and the calender.

5536. *Nothing now remains to be done but pressing*, preparatory to which, the cloth being doubled and laid in even folds, a leaf or sheet of glazed pasteboard is inserted between each fold of the cloth; it is then laid in the press, and covered with thin wooden boards, in which are placed iron plates properly heated; and on the whole the top of the press is brought down, with the degree of force judged necessary to give it the proper gloss. When cold, it is taken out of the press, folded and packed, ready for sale.

The satiny lustre and smoothness given by strong compression with much heat is objectionable, as it renders the surface apt to become spotted and disfigured by rain; this is taken off by steaming and brushing. The difficulties attending the manufacturing fine cloths, with the degree of perfection which the art has now attained, may be easily imagined from the number of necessary processes to complete it, every one of which demands workmen who confine themselves to one process, in order to acquire the requisite dexterity. The whole process occupies about six weeks. The French broad-cloths, particularly those of Sedan and Louviers, formerly surpassed those of all Europe in beauty and perfection. At the former place, blacks are admirably dyed; and at the latter, the wool is still dyed in a superior style, especially for blues.

5537. *The goodness of cloth consists*, 1, in the fineness and softness of the wool; 2, in the clearness, richness, and beauty of the colour; 3, in the yarn being evenly spun, always observing that the warp be closer twisted, and one fourth smaller than the woof; 4, in the cloth having been well wrought and beaten on the loom, so as to be in every part close and compact; 5, in being milled or fulled evenly, clean scoured, and of a proper thickness or substance; 6, in being well dressed, so that the hair, or nap of the wool, be fully and evenly drawn out and ranged on the surface, and in being shorn close, yet without laying the ground or threads bare; 7, in its not being overstretched in the rack, or pulled farther than is necessary to set it smooth, and bring it to its just length and breadth; lastly, in the cloth itself appearing smooth and neat on the face, free from small knobs, spots, and other imperfections; in being firm, yet pliable, and feeling soft and fine to the touch.

5538. *In making mixed cloths*, wool of the different colours, being weighed out in their requisite proportions, are first shaken together; they are then farther mixed by being well turned in the wool-mill; and, by being afterward twice passed through the scribbling engine instead of once, they are generally found sufficiently intermixed.

The dyeing of cloth is a subject on which we do not purpose to enter in this place; but something will be found on the subject under "Dyeing," Book XVII., Chap. II. We shall only observe that the most permanent colour is produced when the dyeing process is performed on the wool before it is woven. Cloth made in this manner is termed *wool-dyed* cloth; whereas cloth dyed after weaving is called *piece-dyed*. Black cloth being very much worn, it is useful to know that there is a very great difference in the durability of the black, according to the process made use of in dyeing it. The most permanent colour dyed in the wool receives a preparation of indigo blue; whereas what is dyed in the piece is prepared with logwood, and the colour is very fugitive; though it looks well at first, it will, after a little wear, turn to a rusty black or gray. To distinguish between such black cloths as have a permanent dye and those which will become rusty and brown after a little wear, provide a little pretty strong solution of oxalic acid in water in a vial; moisten the cork well with the solution, and press it firmly against the piece of cloth to be examined before purchase. If the dye is permanent, in consequence of the use of indigo, the spot that was moistened will, in a few minutes, appear of a greenish olive colour; but if the black be fugitive, the spot will become of a dusty orange or fawn colour.

Formerly, the west of England was the principal locality for the manufacture of superfine cloths; but, of late, Leeds, where, some years ago, only second cloths were made, has become the chief place for the best; and, through the use of so much machinery, the price of superfine cloth has been reduced fifty per cent. Fine cloths may now be purchased for 12*s.* a yard that would formerly have cost 24*s.*

5539. *The worsted or long wool manufacture* is very different from that of cloths. Worsted stuffs require a fine, smooth yarn, which shall have little or no tendency to shrink, curl, or felt when woven. Hence the fibres must be disposed as nearly as possible in parallel lines by the operation of the comb already described, instead of being entangled and crossed by carding, as is required for making cloth. Worsted yarn for warp and weft requires to be even, slender, and hard.

The qualities most required in this kind of wool are length and soundness of fibre; the fineness of the hair is a secondary quality, required only in certain kinds of goods.

The first process in the worsted factory, where *stuffs* are made, is to clean the wool thoroughly, to render it fit for the comber by washing it with soap and water; after which it is spread out upon the floor and dried. The next operation is to comb it, in order to bring the fibres straight.

The old process of wool-combing was this: the wool was oiled, and was first drawn upon the teeth of the wool-comb, with the hand, until the comb was sufficiently loaded; the comb was then placed upon the knee of the comber, and another comb of a similar kind was drawn through it—an operation which was repeated till all the hairs or fibres were brought in one direction. This process required considerable strength, and was generally carried on in rooms which were much heated, because it was necessary that the combs should be kept hot, that they might easily be drawn through the oiled wool; and the workman had a pot made of clay, with holes in its sides, in which he heated them to a certain temperature. At present, wool-combing is chiefly performed by machinery. The first invention of a wool-combing machine was made in 1790, by the Rev. Dr. Cartwright; and patents have been taken out for others, which, owing to the economy of time and material which they produce, have almost wholly superseded combing by hand.

5540. *Worsted was formerly always spun by hand*, as we have already mentioned, as it still is in some places; but when the method of spinning cotton by rollers, invented by Arkwright, was introduced, it was soon applied to the spinning of worsted yarn; and, at present, in factories, it is all spun by machinery, nearly in the same manner as cotton.

SECT. IV.—DESCRIPTION OF THE PRINCIPAL WOOLLEN FABRICS.

5541. *Cloths* are the most important articles in the woollen manufacture. *Broad-cloths* are the stoutest and best, and are seven quarters wide; they are of various degrees of fineness, superfine, second, and inferior. *Narrow cloths* are half the width of the last, or three quarters, or seven eights. *Habit cloths* are a lighter and thinner kind, generally seven quarters wide. *Royal cachmere* is used for summer coating, and is a fine narrow cloth made of Saxon wool in worsted weft.

We have already stated that all our best superfine cloths are now made of Saxon or Spanish wool; an inferior superfine cloth is manufactured from English wools; as also the seconds, chiefly used for liveries, together with coarser sorts, varying in quality and price. The goodness of cloth consists mainly in the quality of the wool, the durability of the dyeing, and the degree of perfection in which the various processes in its manufacture have been performed.

5542. *To judge of the quality of broad-cloth*, particular attention must be paid to the fineness of the fibre and the closeness of the texture. If, on passing the hand lightly in the direction contrary to the nap, there be a general silkiness of feel, uninterrupted by harsh roughness, there are grounds for concluding that the cloth is made of fine wool. The texture should not only be composed of fine threads, but it should have an even consistency, produced by the operation of felting, by which the fibres of the wool are so perfectly incorporated that they conceal the tissue of the threads, and give the entire web the appearance of felt; or, to use a familiar comparison, a piece of cloth made of fine wool, and well wrought and finished, should exhibit no more indications of the loom than a sheet of wove paper does of the apparatus employed in its fabrication. Dealers judge of its quality by an expedient which is more easily understood by observation than description. A portion of the cloth is taken up loosely with both hands; a fold of it being then pressed strongly between the thumb and forefinger of one hand, a sudden pull is given with the other, and according to the peculiar sharpness and vibrating clearness of the sound produced by the slipping or escape of the fold, the goodness of the cloth is judged. Another way is the comparison of various pieces of different fabrics and of different prices; the soft and even consistency, together with the flexibility of fine broad-cloth, will be rendered more evident on being contrasted with that of an inferior cloth. The gloss on cloth is better not to be too satiny, as this causes it to spot with rain.

5543. *Kerseymere*, or *cassimere*, is a twilled cloth that has a greater degree of pliability than plain cloth, and used for garments that are required to be thin and very pliable. From its peculiar texture, one third of the warp is always above, and two thirds below each shoot of weft. It is either single milled or double milled, the last being the stoutest. It is usually woven of the width of thirty-four or thirty-six inches, and reduced by milling to twenty-seven inches. Kerseymeres, and other lighter kinds of cloth, are to be judged of also by the feel; and, as their texture is sometimes not wholly concealed, their quality may be more easily ascertained by inspection. From their twilled structure, they are rendered more durable than plain cloth would be of equal lightness. *Cassimerette* is a variety of the above.

5544. *Pelisse cloths* are twilled and made soft, about seven quarters wide.

5545. *Frize*, or napped coating, is a kind of woollen cloth, or baize, of which one side is covered with little tufts or burrs, called the *frizing*, which is performed by a machine.

5546. *Bearskin* and *dreadnaught* are thick cloths of a long pile, and dyed, intended for very strong, warm dress.

5547. *Bath coating* and *duffel* are light cloths, with a long nap like a double-raised baize, used as winter's dress, for great coats, &c. It is of various colours; also white for women's petticoats. Widths, $\frac{4}{4}$, $\frac{7}{4}$, $\frac{8}{4}$.

5548. *Tweed* is a woollen fabric, of a light structure, lately much employed for summer coating, and for surtouts.

5549. *Swanskin* is a very thick, closely-woven fabric, much used for clothes by seafaring men and labourers; it is employed also as ironing-cloths by laundresses for their tables.

5550. *Hodden gray* is a cloth peculiar to Scotland, manufactured from the natural fleece; throughout the farming districts, the housewives contrive to have one black lamb retained among the flock, as the wool takes on the dye more kindly, and is, indeed often spun into thread for the stockings of the family, without receiving any additional tinge.

5551. *Plush* is a kind of stuff having a sort of velvet nap on one side, composed regularly of a woof of a single woollen thread and a double warp; the one of wool, of two threads twisted, and the other goat's or camel's hair. Some plushes, in imitation of these, are made of other materials. Plush is much used for liveries.

5552. *Flannel* is a woollen stuff, loosely woven, much used as warm clothing. Its warmth is increased by the laxity of its structure; for, as the fibres of the wool touch each other slightly, leaving numerous interstices which are filled with air, heat cannot readily pass through it, as has been shown by Count Rumford. (See "Remarks on Clothing in general.") *Welsh flannel* has the reputation of being the best; but much of what is sold for Welsh flannel is made in various parts of England; a great deal of flannel is made in *Lancashire*. *Patent flannel* is a very fine kind, said not to shrink in washing, an inconvenience which common flannel is liable to. *Gauze flannel* is a flannel of a very loose, porous texture, not so warm as ordinary flannel, and therefore useful for some persons. *Domett* is a kind of flannel, the warp of which is made of cotton and the woof of wool. It is very thin, and useful for some purposes, as linings, and for shrouds for coffins, &c.

5553. *Baize* is a coarse, open, woollen stuff or flannel, having a long nap; sometimes frized on one side, and sometimes not, according to the uses for which it is intended. It was first introduced into England, together with sargs, serges, &c., by the Flemings. It is used for a variety of purposes, for linings, &c.; a good deal is exported. It is generally dyed green and other colours, and is of various width, from a yard to two yards.

5554. *Blankets* are made light, and loosely woven, on which their warmth partly depends. Witney, in Oxfordshire, has been long famous for this manufacture, and the best blankets were formerly, and we believe are still, made at that place. Some blankets are made of felt wool that is wool from sheep-skins, which is divided into several sorts. Of the head wool and bay wool they make blankets of twelve, eleven, and ten quarters broad; of the ordinary and middle sort, blankets of eight and seven quarters broad; of the best tail wool, blankets of six quarters broad, commonly called *cuts*, serving for seamen's hammocks. But the long staple of foreign wool is now much used for the best blankets, and therefore admits of a deeper pile being raised on the surface. As blankets are bulky articles, and go through the same processes as cloth, the machinery is larger, and more easily seen than those used in cloth-making. There is an extensive manufactory at Dewsbury, in Yorkshire, where coals are cheap, driven by steam engines. Nearly 3,000 pair of blankets are made there weekly. Blankets are made of all sizes, up to fourteen quarters wide and fifteen quarters long. Those made for exportation contain two thirds of the low-priced wools of Russia, Germany, Italy, and the Levant: if made all of British wool, they would be too expensive for this purpose.

In the manufacture of blankets, after being woven, they are slightly fulled till they are reduced a sixth. The pile, which is very important, is raised by passing each side of the blanket twice or thrice over rollers covered with brass pins; after this, they are carded, or brushed; but it is to be observed that though by the improved machinery the pile is raised very completely, and the warmth of the blankets is undoubtedly increased by it, yet this does not improve their durability, but the contrary. To be durable, blankets must have a certain weight, a closeness of fabric, and a sufficient quantity of wool in them. It is necessary, therefore, in choosing blankets, to look not merely at the rich appearance of the pile, but also to the weight and texture. Fine blankets are made stouter and heavier than coarse ones.

Stuffs.

5555. The term *stuff* is frequently applied to any woven fabric, whether of gold, silver, silk, wool, hair, cotton, or thread; but is more particularly used to express certain kinds of thin woollen stuffs, used for women's wear, or for linings, as linseys, ratteens, &c. Stuffs properly include all the thin fabrics of long or combing wool known by the general name of *worsted*, as shalloons, lutestrings, florenteens, tammies, moreens, callimancoes, camlets, plaids, merinoes, &c. Their most important distinction is, that they have not their surface covered with a nap or pile. They are woven either plain or twilled, or spotted or figured of various patterns, but in all the varieties the thread is left bare. After the operation of weaving, each side of the piece is drawn rapidly over a convex plate of red-hot iron, to singe off the superfluous fibres of the wool; it is then rolled tight, soaked in hot water, and boiled. Afterward it is scoured, stocked or milled, and pressed between rollers to take out the moisture; it is then dyed, after being passed through a mordant. The subsequent drying is effected by rolling it round iron cylinders filled with steam; and then it is pressed by Bramah's hydraulic presses.

5556. *Moreen* is a very stout stuff made for furniture, and chiefly for window-curtains: it is plain or watered. Some moreen is of a very rich quality, almost resembling silk damask. It may be had so low as 8*d.* per yard, and from that to 3*s.* Width, 26 to 27 inches.

5557. *Lasting* has a double warp, sometimes of two and sometimes of three threads: it is made of various patterns, plain, twilled, or figured, and is distinguished by different names, according to the figures and quality: as *Prunella, Amens* (*probably* from *Amiens* in France), *Florentina*, and *draw-bays*. Width, 18 inches. Generally black: used for shoes.

5558. *Denmark satins* are also used for shoes. Width, 27 inches.

5559. *Ratteen* is a thick woollen stuff, quilled, woven on a loom with four treadles, like serges and some other stuffs. There are some ratteens dressed and prepared like cloths; others left simply in the hair; and others where the hair or nap is frized. Mostly used in linings.

5560. *Merino* is an extremely fine twilled stuff made of the finest wool, used for dresses and shawls. The French excel in the manufacture of this article; some of theirs approximate to Cashmere.

5561. *Merino damask* is a beautiful stuff lately introduced, and much used for window-curtains, covers for sofas, chairs, &c. It is in rich and elegant patterns, in imitation of silk damask.

5562. *Bombazet* is plain and twilled, with warp of single thread, pressed and finished without glazing. Width, 21 or 22 inches.

5563. *Tammies* or *durants*, with single warps, are twilled, and generally coarser than twilled bombazets. Width from 32 to 36 inches. They are highly glazed: mostly used for women's petticoats.

5564. *Callimanco* is nearly the same; plain, highly glazed, twilled, or raised in stripes: used for petticoats.

5565. *Shalloon* is a loosely-woven stuff with a twill, much used for lining various articles of dress. Width from 32 to 36 inches. The name is probably derived from Châlons, in France. It is of various colours.

5566. *Cubica* is a very fine kind of shalloon.

5567. *Serge* is a twilled stuff, of various colours, manufactured in the manner of ratteen; much used for linings of clothes, particularly cloaks. One sort has one side smooth and the other woolly. The longest wool is chosen for the warp, and the shortest for the woof; the former being more twisted than the latter.

5568. *Plaid.*—This term is often applied in England to the colour of stuffs, whereas the term means a peculiar ancient dress worn in the Highlands of Scotland, and was merely an oblong piece of stuff wrapped round the body to defend the wearer from rain. It is always made of a checkered pattern of various colours, there called *Tartan.* Tartan is the name of the colour; plaid is that of the dress. Instead, therefore, of saying "plaid ribands," we should say "Tartan ribands." The true Scotch plaid is a coarse, strong stuff, well calculated to keep out the wet, and is still used by some persons in Scotland, and particularly by our Highland regiments. The stripes and squares formerly varied in their patterns and colours according to each clan; but this distinction is now little attended to. Modern luxury has imitated the pattern of tartan in silk. *Tartan*, or as it is called, plaid, of worsted, is made in various parts of England, and is occasionally used as a cheap and useful material for cloaks.

5569. *Camlet* was originally an Oriental manufacture, a stuff made from the fine hair of the camel; but another material is also used, the hair of the Angora goat, which is of remarkable beauty, being milkwhite, glossy, formed into long spiral ringlets, and exceedingly soft. Angora is a district in Asia Minor, where almost all the inhabitants are employed in the manufacture and commerce of camlets. We have no camlets made in Europe of goat's hair alone. In Brussels, which excels in the manufacture of this article, they find it necessary to mix woollen thread with the hair. Camlets, in imitation of the genuine, are made all of coarsely-twisted worsted yarn, or of worsted and silk, or of these with hair. In some the warp is silk and worsted twisted together, and the woof hair. It is both plain and twilled. What is known here by the name of *mohair* is made of worsted and hair: it is superior to the common, and is used chiefly for military cloaks. An inferior article, made all of worsted yarn strongly twisted, is also called camlet, and is used for ordinary cloaks. Camlet was formerly much in wear; and, from its thickness and warmth, is well calculated for winter clothing for females. It turns the wet better than any other unprepared stuff.

5570. *Mousseline de Laine.*—This is a new species of woollen fabric, of an extremely light texture, first introduced into this country about three or four years ago. It was at first wholly imported from France on payment of a heavy duty, and was sold at a price only within the reach of the wealthier classes; it is now manufactured in this country at a much cheaper rate. It possesses an advantage, that, with great elegance of appearance, it does not ignite on coming into contact with flame, like muslins or chintses. A mixed fabric is likewise made in imitation of it, composed of cotton and wool.

5571. *Challis*, an elegant, twilled, fine, woollen fabric, used for ladies' dresses, ornamented with coloured flowers, which have much the effect of velvet painting.

5572. *Carpets and druggets* have been described under "Furniture," Book V., Chap. X., Sect. III.

5573. *Shawls* are an important part of Eastern dress, and in Asia, among the Arabs, people of Egypt, and Persia, and other countries, are worn by men as well as women. The finest shawls in the world are made in Cashmere, in India: the genuine Cashmere shawl of the finest quality is very costly, and sells in London for from 100*l.* to 200*l.* The material of which they are made is a species of fine hair or wool that grows on a goat which is a native of Thibet, a region which, though situated between the tropics, is yet extremely cold, from its height above the sea. The animal has two kinds of hair; one long and coarse, and another extremely fine, soft, and silky, like down, close to the skin; of the latter the shawls are made. The down produced by a male is about four ounces, and by a female about two ounces. It is estimated that one shawl, fifty-four inches square, requires two pounds of down, and will therefore require the produce of ten goats. The real Cashmere shawls are woven by the natives of the country, and by the Hindoos, in a very simple manner, but become expensive from the slowness of the operation, each loom requiring two persons, and for superior kinds four. These shawls are usually of three sizes; two of which, the long and the small square, are in common use in India; the other, long and very narrow, with a large mixture of black in it, is worn as a girdle by the Asiatics. The manufacture of shawls in Cashmere has decreased of late, owing to the decline of the Persian and Mogul empires. During the existence of the latter, there were 40,000 shawl looms in Cashmere; at present there are not above 16,000; there are still 60,000 persons employed in weaving them. But it appears that in the romantic Cashmere itself not more than 80,000 shawls are manufactured in a year; and from the prodigious number of so-called Cashmeres sold in Europe, they must multiply themselves in an extraordinary manner on their way from that country.

Great pains have been taken to introduce the shawl-goat into France, and with considerable success. M. Joubert found them spread from Cashmere to the Ural Mountains, and he purchased them in Bucharia and Independent Tartary, from which he transported them to the Crimea in 1819, and thence by sea to Marseilles. Though many died on the voyage, four hundred arrived in France safe. It is proper to state that it was M. Ternaux who planned the importation, and furnished the funds for executing it at his own expense and responsibility. The goats have thriven and propagated in France, and shawls have been manufactured from them equal to those of Cashmere. The wool is also brought to Europe from Cashmere by way of Casan, the capital of a Russian province on the Volga; it is spun and woven in France, either mixed with silk or without. At first they succeeded in imitating the real Cashmere shawl only on one side, but they are now able to imitate perfectly the texture of the true Oriental fabric. Women are employed in weaving the *French Cashmere*, and it requires the work of four hundred days by a woman and two apprentices to complete one. Various other shawls are likewise made of mixtures of the Cashmere wool with silk, extremely beautiful, and nearly equal to the Oriental. The best are made in Lyons, and some inferior at Nismes. The extraordinary passion of the French ladies for these shawls is well known. Four Cashmere goats were introduced into Essex by Mr. Towers, of Weald Hall, in 1828, and had increased in 1833 to fifty; they thrive very well, feeding like sheep, but chiefly on furze, and their wool has been manufactured in England; but it is not probable, from the small quantity produced by each goat, that the manufacture will be profitable in this country. Cashmere wool is also brought here by our East India shipping, and sent to France to be spun into yarn for the weaver; some also has been spun here by machinery. Lately, a breed has been produced in France between the Angora goat and the Cashmere, which promises great success, producing a considerable quantity of wool, long, fine, and glossy, combining the softness of Cashmere with the lustre of silk, being the most beautiful filaceous material known, and in every respect fitted for the purposes of shawl weaving. Some of these goats yield thirty ounces of fine wool in one season. A few of these have lately been brought to England.

5574. *Excellent imitations of Cashmere shawls* are now manufactured in this country of the finest Saxon wool, particularly by Messrs. Frost, Nelson, and Co., at Leeds; the fringed borders are made in London and in Scotland, and are sewed on.

5575. *Shawls of a cheaper kind*, of great variety, are likewise made in various parts of Britain, particularly at Huddersfield, Norwich, Paisley, &c.; in the latter place they are manufactured of very elegant patterns. From their convenience, they are now worn by all classes, and the cheapest kinds are too well known to require description.

5576. *The manufacture of worsted stuffs was first introduced into England* in the reign of Henry I., by some Dutchmen who had been driven from Holland by an inundation of the sea. They settled at Worsted, in Norfolk, whence the name; and a charter was granted for the manufacture of worsted stuffs, in consequence of which that city became one of the most flourishing in the kingdom, and there these stuffs were long made in the greatest perfection.

At Leeds are sold a large quantity of worsted stuffs at prices thirty per cent. cheaper than they were twelve or fourteen years ago, owing to the use of machinery and the low price of British wool. The worsted is chiefly spun and woven at and near Bradford, and in Lancashire; the finishing and dyeing are performed at Leeds. It is said that in the West Riding of Yorkshire 40,000 pieces of stuff are made per week. Perhaps the most considerable stuff manufactory in the kingdom is at Burley Mill, two miles west of Leeds: in this there are four hundred power-looms, which weave six thousand yards a day; and it is reckoned that twenty times as much more is made by hand-looms in the adjacent country.

For carpets, see "Furniture," Book V., Chap. X., Sect. III.

5577. *Fleecy hosiery* forms a very useful kind of manufacture: it consists in interweaving fine fleeces of wool into pieces of the common stocking texture. It is not confined to stockings; but webs of it are woven, which can be cut up and made into under waistcoats, socks, or other articles. Its warmth exceeds any other woollen fabric, and hence it is a valuable material for valetudinarians, or for common use in a very cold climate.

CHAPTER III.

LINEN FABRICS FOR CLOTHING AND FURNITURE.

SECT. I.—HISTORICAL AND GENERAL REMARKS.

5578. *The use of linen is extremely ancient: it was the national manufacture of the Egyptians in the time of the Pharaohs;* and the prolific borders of the Nile furnished, from the remotest periods, as at the present time, abundance of the finest flax, the plant from which linen is prepared. The Egyptians exported their "linen yarn" and "fine linen" to the kingdom of Israel in the days of Solomon, and their "fine linen with broidered work" to Tyre, as also the same kind of cloth to Greece in the days of Herodotus. It appears from sacred and profane history, that linen continued to form the most esteemed clothing in Egypt till after the Christian era.

5579. *Specimens of Egyptian linen*, at least three thousand years old, are preserved in abundance in the numerous swaddling-bands in which the mummies are wrapped up, and these show that the arts of spinning and weaving had advanced to great perfection; for not only is the linen very similar in every respect to what is made at present, but some of it is of extreme fineness, resembling fine muslin or cambric, though evidently made of flax. It is also met with striped and dyed blue and yellow. The quantity of mummy-cloth found in the mummy pits and sepulchres of Egypt is so great that it has even become an object of speculation in Egypt to employ it for making paper.

5580. *From the Egyptians, the neighbouring nations, the Jews, Greeks, and Romans*, learned the manufacture of this material, which was held in such high esteem that it was used as raiment for royalty; but linen was among them extravagantly dear, being either imported or made by slaves, few of whom were sufficiently skilful.

5581. In modern times, the manufacture of linen arrived at the greatest perfection in Flanders; and it was not in common use in England till 1253, when it was introduced by the Flemings, woollen shirts having been worn before that time. In 1368, a company was formed in London for manufacturing it, and Lord Wentworth introduced it into Ireland in 1634. The inhabitants of the Netherlands, however, long excelled us in its fabrication, and the finest linens, called *Holland*, were imported. At present very little comes from abroad, the production of the Irish and Scotch looms being more than sufficient for home consumption. The linen trade of Great Britain has been more than doubled within the last forty-five years, owing greatly to improvements in flax-spinning. The manufacture here may now be valued at eight millions sterling annually, employing 180,000 hands, young and old. The value of the export of linen and yarn may amount to a million and a half sterling.

Sect. II.—Description of the Flax Plant, and Preparation of Flax

5582. *Flax* (in Latin *linum*, whence the word *linen*) *is a plant* of which there are several varieties; but the common flax plant (*Linum usitatissimum*, *fig.* 783) is an annual, having a slender, smooth, hollow stalk, rising to the height of about two feet; the stem then divides into several branches, which are terminated by handsome, blue, glossy, veined flowers, to which succeed roundish pods or seed-vessels, about the size of a pea; each of these contain ten little seeds full of meal and oily matter. The leaves are long, narrow, and sharp pointed. Flax is cultivated more or less in most countries of Europe, and succeeds best in a rich, deep, loamy soil, with a good deal of moisture; but good crops are also produced upon stiff land. Flemish flax is the best; but vast quantities are also imported from the Baltic. Owing to the cheapness of foreign flax, little is grown in England.

Fig. 783.

5583. *The filaments of flax employed for making thread* are composed of the bark, or fibrous covering of the stalk. The plant is suffered to grow till its seeds are ripe, and is then plucked up by hand and laid in little bundles to dry.

5584. *The first process in preparing flax* is termed *rippling*, and consists in forcing off the seed-vessels; this is done either by beating them off or by pulling the plants through a kind of comb with iron teeth, set so close that the heads cannot pass, and are consequently pulled off. To obtain the seeds, the pods, or capsules, are broken by treading or threshing, and the whole is winnowed to drive off the chaffy matter. The seeds afford oil by pressure, and the refuse oil-cakes serve to feed cattle, and for manure.

5585. *The next operation is to obtain the flaxen fibre clean and free from all other material.* We stated that this fibre is the bark of the plant, and some process must be employed that shall destroy the parenchymatous matter, or the internal part of the stem, and leave the fibre uninjured. This is effected by several methods. 1. The flax, tied lightly in bundles, is put into a reservoir of soft stagnant water to steep; by this a slight fermentation takes place in the inner substance, and in a few days it begins to rot; as soon as this occurs, the flax is withdrawn from the water before the decomposition has had time to extend to the fibres themselves. This process is the most disagreeable thing belonging to the management of flax, since the smell arising from the rotting, or *retting*, as it is called, of the gummy or mucilaginous matter which holds the fibres together is extremely offensive and prejudicial to health, and the infected water is apt to kill the fish which swim in it. Endemic fevers are common in districts where much flax is steeped. Great skill and precaution are necessary in this part of the operation; if the flax be left too long in the water, the filaments will become rotten and useless, and if not long enough, they will not separate with sufficient ease; it is better to take it out rather at an earlier period than to leave it too long in the pits. The time it should remain will depend upon the degree of ripening of the flax, and the temperature of the water. The mode in which the skeletons of leaves are prepared will illustrate this process. If leaves of trees be suffered to lie for some weeks in water, the pulpy matter will decay, so as to be removed by the slightest rubbing, while all the veins of the leaves remain uninjured; these veins are similar in point of strength to the bark of the flax, and both remain equally entire after the soft matter has rotted. It is the acetous fermentation that takes place in retting, and the flax is to be taken out as soon as this fermentation is finished, and before the putrid begins. 2. The flax is sometimes laid in running instead of stagnant water; in this case the decomposition does not go on so rapidly, and it will be several weeks before it is sufficient, but the fibres will be very strong. 3. Instead of laying the flax in water, it is merely spread upon the grass, and the joint action of rain and dew effect the same thing in about six weeks that took place in the steeping process. This method is practised in Devonshire, and in various places on the Continent, and is favourable to preserving the strength of the fibre, though steeping is the most general process. After steeping, the flax is spread out upon the grass, for the purpose of rectifying any defect in the watering, and for carrying on the decomposition to that point when the fibre will separate from the *core*, or *boon*, as it is called, with the greatest ease, which is known by rubbing some between the hands.

5586. After the retting, the *harl* still contains, besides the textile filaments, a certain portion of the glutinous cement which is not soluble in water; and the destruction of this by putrefaction alone cannot be carried to the last without injury to the flax; it is, therefore, effected by exposure to the weather. Dew-retting is the safest, and does not produce the same noxious air; the length of time required is the only objection. Mixed retting is sometimes preferred, where it is begun in water and is finished by the dew.

5587. *The smallest filaments of flax* readily separate from each other when delicately washed with hot water or an alkaline lye, or when a thread of cloth is dissected with a needle point. They have an average diameter of $\frac{1}{2500}$ of an inch. Different specimens of flax separate into these minute fibrils with different degrees of facility, and thereby create different grades of value for the fine spinner. Good flax should be long, fine, glistening, and soft like silk, of a silver gray, neither greenish nor blackish.

5588. The flaxen fibre, having been thus rendered easily separable by the retting, is next to be *dressed*, a term which includes the various processes for bringing it into a state proper for the fabrication of cloth and other articles.

In flax-dressing the first process is the *scutching*, or separating the fibre itself from the core. This was formerly effected by an instrument termed a *brake*, which has blunt teeth or knives that are forced down upon the flax. This was formerly worked by hand, but the operation was afterward more expeditiously executed by machinery turned by water or other power; rollers are now frequently used in Britain instead of the brake. But the whole of the woody matter is not detached by the brake or the hammer, and rubbing is also employed; this is done by laying some flax upon the knee and scraping it with a blunt knife. There are some slight modifications in the dressing, according to the kind of cloth to be made from the flax, whether linen, lawn, cambric, &c.

5589. *Hackling* is the next operation in flax-dressing. The hackle is a strong comb composed of several rows of iron or steel teeth several inches long, fixed upright in a block of wood as a base, made fast to a bench, and the workman strikes a lock of flax across the pointed summits of these, and draws it through. Coarser and wider-toothed hackles are used first, and then others progressively closer-toothed as the fibres become finer by separation. In manufactories the hackling is now performed by machinery. By this process the filaments are separated from each other; the shorter fibres unfit for spinning are taken out, and the longer ones are arranged in a parallel manner. To assist the hackling in splitting and separating the filaments several methods have been resorted to. In some places, flax is beat with a wooden mallet, having a fluted face, upon a block, after and between the hackling. Brushing with a very stiff brush made of swine's bristles is another method.

The coarse entangled fibres which are separated by the hackle are called *tow*, and the hackled flax is termed *line*. The line is now carried away to be sorted, according to the various qualities in respect of fineness; it is then ready to be spun.

5590. Since subjecting flax to the process of retting is not only tedious, but liable to injure its strength, attempts have been made to hackle and dress it without retting, by means of machines; but it has been found that the flax thus prepared was not equal in quality to that which has been retted by the old processes.

Sect. III.—Manufacture of linen fabrics.

5591. *The spinning of flax by the domestic or flax wheel* was described in page 932; but this process is now effected in factories nearly in the same manner as cotton by more complicated machinery, which produce yarn with much greater rapidity. But the spinning of flax by machinery has been found more difficult than that of cotton or wool, and therefore it is but lately that manufacturers have succeeded in it. It was in Leeds that this was first effected, in a degree little short of the spinning of cotton. The flax is then first formed into a *roving*, and that again made into *yarn*. But in spinning this material it is necessary to pass it through water, which occasions a dewy spray to be thrown, extremely inconvenient to the spinners, as it wets their clothes. Hot water is now used instead of cold, which in some degree obviates this inconvenience, and produces a smoother thread. The thread, or yarn, is of various degrees of fineness, some of which is twisted hard to serve for warp, and the rest has a softer twist given to it, that it may have the yielding consistence of weft. A pound of flax is divided into so many hanks; and the number of hanks is the commercial name or number of the thread. Low numbers are used for sail-cloth, sacking, &c.; from 20 to 40 for sheeting, drills, table-cloths, &c.; Irish linens from 60 to 100 and upward; cambrics require from 120 to 200.

5592. *The process of weaving linen cloth* by hand-looms is the same as has been described under the article "Weaving," which see; but of late the power-looms have been adopted for weaving all but the finest and most costly fabrics. Figured or fancy cloths, as damask, diaper, &c., are wrought by a particular modification in the draught of the loom and cording of the harness, the effect of which is to produce alternations in the twill or flushing of the warp and woof at certain intervals, according to the pattern prescribed The plain cloth most in demand for personal use is principally manufactured in Ireland.

5593. After the making of linen cloth has been completed by the weaver, it has to go through the important process of bleaching, to render the cloth perfectly white; but as the proper bleaching of linen now seldom becomes an affair of domestic economy, and as its principles are very important to throw light on the operations of the laundry, we have considered that the most useful arrangement would be to connect it with them; and therefore we refer the reader to the subsection "Bleaching," in Book XXII., "Laundry."

SECT. IV.—DESCRIPTION OF FABRICS MADE OF FLAX AND HEMP.

5594. *Linen.*—The cloth so named, from the Latin *linum* (flax), is the principal fabric manufactured from flax, and is used mostly for shirting and sheeting. The fineness of linen is determined by the relative length of yarn in a given weight, and also by the number of threads of warp contained in a certain space of the reed in weaving, to which the threads of weft in a similar space must bear a fixed and regular proportion. In judging of linen of whatever fineness and price, particular attention should be paid to the evenness of the threads, and also to the firmness and closeness of the texture. The colour should be perfectly white, and the surface glossy; but this gloss should be principally, if not wholly, the effect of the calender employed in finishing the cloth. Many inferior fabrics are rendered marketable by a large proportion of starch, from which they receive not only a fine gloss, but also a factitious hardness, or *body*, as it is termed, qualities which disappear after the first washing; and the cloth, having lost in this ordeal all its vellum-like consistency, becomes, to use a familiar expression, "as poor as a rag." Hardness and smoothness, therefore, can never be safely depended upon as a criterion; the eye must be rather closely applied to discern whether these qualities actually proceed from the strength and fineness of the fabric. The threads must not only be even, but must have a certain wire-like roundness; a magnifying glass is very useful to examine the texture of linen by; but the purchaser should be in the habit of using it, otherwise he will be misled. Some linen is sold free, or nearly so, from this *dressing*, and such is to be preferred. The kinds of linen for shirting manufactured here are *Irish*, *Scotch*, and *English*, of which the first is reckoned the best.

5595. *Holland*, a fine kind of linen imported from the Low Countries before our manufactures had arrived at such perfection, was in great request for wearing apparel; at present very little foreign linen is imported.

5596. *Dowlas* is a very strong, coarse Irish linen cloth, made for shirts.

5597. *Drill* is a very stout twilled linen, made for summer trousers.

5598. *The linens usually selected for sheeting* are, Irish, union Irish, which has a mixture of cotton, Lancashire linen, and union Lancashire, Russia, imitation Russia, Yorkshire, Barnsley, and Scotch sheeting. The widths of these are from $\frac{7}{8}$ to $\frac{14}{4}$. The principal requisites in sheeting are strength of thread and closeness of texture. The strongest coarse sheeting is that of Russia, which may be had of various widths, from an ell to two yards and a half.

5599. *Unbleached linens* are used for various purposes. *Brown Holland* is much used for upholstery, Widths, $\frac{3}{4}$, $\frac{4}{4}$, and $\frac{5}{4}$. It is glazed, and of various degrees of fineness; and there is also a *rough brown Holland*, not glazed. *Silesia* is a fine brown Holland, glazed, for roller window-blinds, of various widths, from 28 to 90 inches. *Hessia* and *Forfar* are very coarse linens, used for various purposes, as straining on sofas, &c.

5600. *Brown damask* is a coarse damask, unbleached, used for table-cloths for the nursery, &c. It is reckoned stronger and more durable than what has been bleached.

5601. *Linen Damask.*—This name is given to a twilled linen fabric of a similar structure to the silk fabric of that name. It is very generally used for table-cloths and napkins. In respect to fineness of fabric and beauty of designs, the French damask long bore the pre-eminence, but it is now surpassed by that of Silesia, some of which are eight yards long and two wide. Considerable quantities of damask are made in Scotland, particularly at Dumfermline, in Fifeshire, and likewise at Lisburn and Ardoyne, near Belfast; some superb examples have been executed at these places. Dutch and Italian damasks are also imported. The designs for this fabric are first drawn upon paper, and any patterns can be executed, such as family arms, &c., with the admirable machinery now in use; although, when the patterns are complicated, the article becomes very expensive.

5602. *Diapers* are allied to damasks, but of simpler and smaller patterns; they are made for inferior table-cloths, and for napkins, towels, and various domestic purposes. Those distinguished by the name of *union* are composed of linen and cotton; and there are also cotton diapers.

5603. *Dorrock* is a coarse linen fabric used for common household wear, nearly resembling diaper, and ornamented with squares. It derives its name from the town of Dorrock, in Scotland, where it was first manufactured for table-cloths.

5604. *Huckaback* is something similar, but has no beauty to recommend it; it is, however, a most durable and economical linen, and much used for towels.

5605. *Tick* is a well-known cloth used for bed, bolster, and pillow-cases.

Besides the above, there are an infinity of smaller articles made of linen, too well known to require being described in detail; as *girths* and *tapes* of various kinds, viz., Manchester, Holland, black tape, pink or red tape, stay-tape, &c.

5606. *Cambric* is an intensely fine and beautiful cloth of flax, first made, it is said, by Baptista at Cambray, in the Netherlands, from which it is named *Batiste* on the Continent.

5607. *French cambric*, when genuine and of the best kind, is still superior to our manufacture. It possesses a peculiarly beautiful silky appearance, and is imported in boxes of twenty-five pieces, each containing 7½ yards, of ⅝ or ⅞ widths, but are liable to a heavy duty. Much more was formerly used when frills and ruffles were in fashion for shirts. *French cambric handkerchiefs* are of three widths, ⅝, ¾, and ⅞. The finest are sometimes fringed.

5608. *Irish and Lancashire cambrics* sometimes come nearly up to the French in quality; but little of this is made.

5609. What is called *Scotch cambric* is, in fact, a cloth made of cotton, in imitation of French cambric, which we stated s of flax. It is much inferior in retaining its whiteness. Some of the best Scotch cambric handkerchiefs are made of flax intermixed with cotton.

5610. *Lawn* is also originally of French manufacture; it is thinner and more transparent than linen, and comes near to cambric. The thread for it is made so as to be as cylindrical as possible, and it is not pressed so much as calicoes. The Irish is next to the French: there is also Scotch lawn.

5611. *Fine canvass* is the coarsest fabric made from flax; common canvass, of various degrees of coarseness, and used in furniture, for papering, &c., being made from hemp.

5612. *Hemp* (*Cannabis sativa*, Linn.) is a plant, the fibres of which are coarser and stronger than those of flax. Hemp was originally a native of Persia, but has been naturalized in Europe. It grows about three feet high, the stem branching with alternate leaves on long foot stalks, and flowers in clusters, male and female distinct. The coarsest canvass is used for sail-cloth, for tents, and similar purposes; and the preparation of yarn from hemp is so similar to that from flax as not to require a particular description. Some hemp is grown in Britain, but by far the largest quantity is imported from Russia and Poland. Other articles are likewise made from hemp, as a kind of huckaback, and some sorts of cloths for husbandmen and labourers; likewise, cords and ropes of various kinds. *Buckram* is a sort of coarse hempen cloth, woven very open, and stiffened with gum: it is used for stiffening various parts of dress.

CHAPTER IV.

COTTON FABRICS FOR DRESS AND FURNITURE.

SECT. I.—GENERAL AND HISTORICAL REMARKS.

5613. Cotton, from its great abundance and comparative cheapness, as well as from the facility with which it may be wrought up by machinery, has, to a considerable extent, superseded wool, silk, and linen as a material for many articles of dress, both useful and ornamental. The more common fabrics made of this substance have, in general, obtained the preference over the light worsted and linen stuffs that were formerly used for linings. Cotton cloth is found eligible both for shirtings and sheetings; fustians have been found a more durable kind of raiment than the common woollens for labourers; while muslins, having been very extensively adopted as an article of dress for ladies, have greatly diminished the consumption of those silk and linen fabrics to which the choice of female dress was formerly limited. It may be added that the more common manufactures of cotton, after being dyed and printed, have supplied the middle ranks with a cheaper and more elegant material, both for dresses and furniture, than were in general use in former times.

5614. The cotton manufacture in this country likewise exhibits a striking example of the advantages to be derived from the exercise of the inventive faculty. Within the memory of persons now living, it has sprung up from insignificance, and has attained, in the space of forty years, to be one of the most flourishing and important branches of our national industry; in this respect surpassing the manufactures of wool and linen, which have existed among us for centuries. But the utility of cotton fabrics is too generally understood to require any detailed eulogium; and the varieties of them will be best understood after we have described the general processes by which they are produced.

5615. *The history of the manufacture of cotton cloth* will properly precede our account of the improvements which have caused it to come so extensively into use, and will enable us to throw light upon many circumstances respecting the varieties of the fabric that would otherwise be, in some degree, obscure. The earliest accounts given by historians and travellers of the intertropical countries of Asia describe the inhabitants to have been acquainted with the fabrication of cotton cloth; but the commencement of its use is unknown. Herodotus, who wrote 440 years before our era, distinctly notices cotton fabrics as the common clothing in India; and he observed that the material was the produce of a plant. Cotton is again mentioned by Arrian, who lived in the second century, in his account of the voyage of Nearchus down the Persian Gulf; and likewise by Strabo, who speaks of flowered cottons and chintses. Pliny describes the cotton plant very accurately, stating it grew in Upper Egypt; yet the manufacture of it does not appear to have been practised by the early Egyptians, since no cloth of this kind is found among the numerous swaddling-bands wrapped round their mummies. It is, indeed, a remarkable fact, that the cotton manufacture remained insulated in India for many centuries, even after a considerable intercourse with the East had been established by Europeans, and notwithstanding the vicinity of Syria and Egypt to that region. The Arabian traders brought Indian cottons of various kinds, as calicoes, muslins, plain and flowered, to Aduli, a port in the Red Sea, and thence they found their way into Europe; but they were probably extremely rare for several centuries, as well as the silks of China. At length, cottons and muslins came into general use among the Arabians and the neighbouring nations, and the manufacture itself was spread, through their commercial activity and enterprise, throughout the extensive territories subdued by their arms.

We learn from the travels of William de Rubriquis, in 1252, that cottons were then articles of trade and dress in the Crimea and Southern Russia; and Marco Polo, the Venetian traveller, observed cotton cloth to be woven in the province of Fokein, in China; but it was not until after the conquest of that country by the Tartars, in 1368, that cotton became the general dress of the lower classes, as silk was, and continues to be, that of the wealthy. The Chinese at present, however, do not grow cotton sufficient for their own consumption, but import a great deal from Surat, Bombay, and other parts of India, and, of late, from this country.

The cotton plant grows wild also on the borders of the African rivers Senegal, Gambia, Niger, &c., and on the coast of Guinea; and the barbarous or semi-barbarous nations there are clothed in their own cotton manufactures, often dyed and figured, and sometimes interwoven with silk. In 1590, cotton cloth of native manufacture was brought to London from Benin, on the coast of Guinea; and many centuries before that it had been made in Morocco and Fez.

It is deserving of notice that, before the discovery of America by the Spaniards, cotton formed the principal article of clothing among the Mexicans, who had neither wool nor silk; and though they possessed flax, yet they did not employ it in clothing. An ancient Mexican dress of cotton is preserved in the British Museum.

5616. The introduction of this manufacture into Europe was originally effected by the Arabs or Moors of Spain, who brought the cotton plant to that country, as well as the sugar-cane, rice, the mulberry, and silk-worm, in the ninth century. Fustians were first made at Barcelona, the name being derived from the Spanish "fuste," substance; and stout sail-cloth was also manufactured of cotton at the same place. But the arts of Spain did not spread throughout Christian Europe, and finally were lost by the expulsion of the Moors. It is remarkable that the Europeans alone continued destitute of this admirable produce of industry for many thousand years after it had been possessed by nations whom they looked down upon as inferiors.

5617. Cottons and muslins were brought from India by the Portuguese, after their discovery of the Cape of Good Hope; and the Dutch and Flemings, who rivalled them in this branch of commerce, began to fabricate cotton cloth at home.

5618. *The first notice we find of the importation of cotton into England* is that from the Levant; and it appears to have been employed chiefly in making candle-wicks; if at all woven, cloth was made only in very small quantity. The Protestants, driven by persecution from the Low Countries, brought the cotton manufacture to Bolton and Manchester in the reign of Queen Elizabeth, who saw the policy of protecting and patronizing so valuable an art. But it is not to be supposed that the cottons at first manufactured in England resembled in any degree the delicate fabrics of India. Those which were made at first in Manchester appear to have been chiefly fustians, in which only the weft was of cotton, the warp being of linen yarn, chiefly from Germany and Ireland. Owing to the rudeness of the spinning apparatus at that time, cotton yarn, sufficiently strong and regular, could not be produced for the warp (which is always the principal portion of the web), and, consequently, such fabrics, consisting of linen warp and cotton weft, could scarcely be denominated cottons. In the mean time, importations from India, by the Dutch and East India Companies, of calicoes, muslins, chintses, and other fine fabrics increased; and articles from that country became so fashionable that the dress of the ladies and the furniture of the houses were almost supplied by the Indian trade, to the great discouragement and prejudice of our home manufactures, particularly the woollen. This occasioned a loud outcry in 1700, and produced an interference of the Legislature. Silks and printed calicoes for domestic use, either as apparel or furniture, were prohibited, or loaded with heavy duties. As the cotton manufacture slowly increased, it was found difficult to procure linen yarn for the warp without inconveniencing the linen weavers; nor could the cotton weft be produced in sufficient quantity by the wheel then in use. The demand by the merchants set invention to work, and the discovery of machines by which, instead of the one-thread wheel, at that time the only one, twenty, fifty, or even a thousand threads could be spun at once by a single pair of hands, produced a new era in the manufacture of cottons.

But before we proceed with the history of this interesting event, and the various improvements by which the cotton manufacture has arrived at its present perfection, it is necessary that we describe the nature of the raw material, and the process by which the downy substance produced by the cotton plant is converted into such a variety of beautiful fabrics.

Sect. II.—NATURAL HISTORY OF THE COTTON PLANT.

5619. *The fleecy substance called cotton wool grows upon a plant of which there are several species,* which, however, may be generally included in three classes: 1. An annual or herbaceous plant, usually two or three feet in height, or about the size of a gooseberry bush; 2. A shrub, six or seven feet high; 3. Tree-cotton, rising to the height of twenty feet. This last is found only in tropical countries. The Linnæan name of this genus of plants is *Gossypium*, and it belongs to the natural order of Malvaceæ or Mallows. The leaves of the herbaceous varieties, which are the most common, much resemble those of the vine, but are smaller. The blossoms expand into a pale yellow flower (*fig.* 784), which changes to red, and then to brown. When the cotton plant has arrived at maturity, and the flower falls off, a capsular pod appears, approaching the triangular shape, with a pointed end, and supported by three triangular leaves. It increases to the size of a large filbert, and becomes brown as it ripens. The expansion of the wool causes the pod to burst in two or three gaping segments, when it discloses a ball of downy cotton, of a white or pale yellow colour, consisting of three locks, which are contained in as many cells in the pod. This wool encloses and adheres firmly to the seeds, which in form resemble those of grapes, but are larger.

Fig. 784.

5620. *The natural colour of cotton is white,* or cream coloured, iron yellow, or tawny. The filaments vary in length from half an inch to one inch and three quarters, according to the variety of the plant, tapering to a fine point at the ends, and are about the two thousandth part of an inch in diameter; they are pretty uniform in the same crop. They are sufficiently long and tenacious to bear twisting into an extremely fine thread; and, of all the materials for this purpose, they are the easiest twisted. Under proper cultivation, cotton may be raised in such abundance as to form the cheapest material for clothing. When examined by the microscope, the fibres appear to be flattened cylinders, and rather two-edged or triangular, and not to be straight, but contorted; a structure which causes the fibres slightly to adhere together, and thus give warmth to cotton clothing.

5621. *The cotton plant requires great care in its cultivation,* as it is delicate and easily injured; but it does not demand a rich soil. It is produced from seeds, which are sown rather thick, and the plants are thinned as they grow up, and transplanted at proper distances. The plough is used in some countries, and a good crop produces thirteen pounds of cotton per acre. In every country cotton grows best near to the sea. In India, the best cotton is not far from the coast; when tried at Benares, four hundred miles inland, it failed. The finest cotton of America is from the seacoast. In some places the plant is an annual; in others it is perennial; the difference of longevity being partly owing to climate and partly to husbandry. Some shrubs will thrive for eight or ten years, and some of the finest cotton of India grows on trees which rise to the height of fifteen or twenty feet.

Sect. III.—PREPARATION OF COTTON WOOL FOR THE MANUFACTURER.

5622. *The operation of gathering the ripe cotton demands great care;* as all the pods do not get ripe at once, the people must go through the plantation, and select such only as have been opened a few days. Fine weather is chosen for this purpose, because wet would cause the cotton to become mouldy, and to prevent which it is thoroughly dried in the sun.

5623. *As the downy fibre adheres to the seeds, to detach it from the latter is a work of some difficulty,* and must be performed before the cotton is packed. A man with his hands only could not clean more than a pound in a day; therefore all nations who have advanced from barbarism use some kind of machinery for the purpose. In India, a rude hand-mill, or pair of wooden fluted rollers, is employed, by which from forty to sixty-five pounds per day may be cleaned. In other countries wooden rollers of a somewhat similar construction are employed, but they are moved by machinery instead of the hand. The cotton wool is then carefully sorted and freed from any imperfect parts or particles of dirt; after which it is well dried, put into bags, and pressed into bales in a small compass, for the greater convenience of transportation. It is brought to the mills in Britain in bags weighing from 330 lbs. to 350 lbs., just as it is packed up, and is then stowed in warehouses, being arranged according to the countries from which it may have come. From the very great pressure to which it has been subjected in packing, it is found to be in hard, matted lumps; and it also still contains some seeds and dirt. It is, therefore, put into a machine called a *willow*, which, by its revolving spikes, tears open the cotton, and, by the blast of a powerful fan, or *blowing* machine, frees it from most of its seeds and other impurities. It is next taken to the *scutching* machine, by which it is more completely opened and cleaned, being beaten with metallic blades revolving on an axis; in this way all the fibres are opened, and the seeds and dirt fall down through a frame of wire-work. Before the invention of this last machine, the cotton was beaten with switches, which is still practised with the finest kinds. The cotton is now taken to the *spreading* or *lapping* machine, the effect of which is to spread it out equally into a broad, soft, fleece-like wadding, and to roll it upon a roller, so as to be in a proper state to be conveyed to the *carding* machine.

5624. *The object of the carding operation is to separate the fibres*, which, in their imported state, are entangled in small tufts and knots, and which have been but imperfectly opened by the last operations; by carding they are drawn in a parallel direction, and all residuary impurities are removed. The cards are a kind of brushes formed of little bent pieces of wire fixed in leather, which is attached to wood. At first, these cards were flat, and were worked by hand; but they are now made in the form of cylinders, which move against each other with different degrees of velocity, being turned by machinery. By the carding machine the cotton is likewise brought into the forms of a sort of ribands, called card ends or slivers, preparatory to spinning.

The Spinning of Cotton.

5625. *The spinning of cotton* is that part of the manufacture which has gone through the greatest revolutions; and these have led to an extraordinary change in the production of cotton cloth.

Previously to the year 1760, the cotton manufacture of England was nearly as simple as that of India, though the loom was better constructed, and the carding of the cotton had been imitated from the wool manufacture. The spinning of cotton was all performed in this country on the one-thread wheel (see "Spinning," Book XVII., Chap. I.), nearly in the same manner as wool, a process far too slow to supply the weavers with weft in sufficient quantity to enable them to answer the demand for cotton cloth; and the weft spun of cotton by hand in this manner was a very irregular thread, produced by women of various degrees of skill. The spinning was effected by the female part of numerous cottages dispersed through the country, while the families were employed in weaving the yarn or thread into cloth; this, when finished, was disposed of to agents sent round by the Manchester merchants. But the weaver's own family seldom could supply him with a sufficient quantity of weft; and he had with much pains to collect it from neighbouring spinsters, which occasioned a loss of time, and greater expense for yarn. This difficulty was likewise aggravated by an invention which John Kay had made in 1738, of a machine called the "fly shuttle," by which the process of weaving was expedited, enabling the weaver to make twice the quantity of cloth in a certain time; but it was only in 1760 that this invention was adopted in cotton weaving.

5626. *The first great improvement in the manufacture of cottons* was the construction of a machine called the *spinning-jenny*, by which, instead of one spindle and one thread at a time, a single person could spin eight threads at once with the same facility as one. This ingenious piece of mechanism is generally ascribed to James Hargreaves, a weaver in Lancashire, in 1767; and it was subsequently so improved that a little girl could work from eighty to one hundred and twenty spindles. The spindle in the common wool and cotton wheel was always horizontal, but the spindles in the jenny were upright, or very slightly inclined from the vertical, a position essential to its due operation. But the jenny was applicable only to the spinning of cotton for weft, being unable to give to the yarn that degree of firmness and hardness which is required in the warp: consequently, although it made up for the slowness of the common wheel, enabling the weavers to produce much more cloth, still this cloth remained, as before, composed of a linen warp and cotton weft, and no goods could yet be made all of cotton. Hargreaves contented himself, for some time after, with spinning weft, with the assistance of his family, for his own loom, receiving his warp, according to the custom of the weavers of that time, from the wholesale manufacturers. The secret of his invention at length, however, transpired; and the facility and quickness with which yarn could be produced by its means, excited such a tumult among the neighbouring spinsters, that they broke into his house in a riotous manner, and destroyed his machines. He then removed to Nottingham, took out a patent for his machine, and dispersed them through the district. It has been said that he died in poverty, but it appears from the account of Mr. Baines (to whose excellent work we are indebted for many of the facts detailed respecting the cotton manufacture) that this is an error, and that he was enabled to leave a decent provision for his family. Still no fabric could be executed entirely of cotton, and another invention was wanted to produce cotton yarn sufficiently firm for the warp of cloth.

5627. *The discovery, in 1768, from which only can be dated the proper manufacture of cotton cloth in England, was made by Arkwright, afterward Sir Richard,* a native of Lancashire, and who, though originally a barber, and uneducated, yet possessed a strong natural genius for mechanics. It has been said that he was not solely the inventor of his machines; but this statement has probably originated from the assistance he obtained from various mechanics, which almost every inventor requires in order to perfect his work. Indeed, supposing that he was not entitled to all the merit that has been claimed for him, it must be allowed that he possessed a very high inventive talent, as well as great sagacity in estimating at their true value the mechanical contrivances of others, in combining them together, and arranging a complete series of machinery. Nor did his genius confine itself to the invention of machines only; he improved every part of the process of manufacturing cotton, and, being a man of business, he, in conjunction with Messrs. Strutt and New, whom he took into partnership, introduced an order and system into factories before unknown. Mr. Strutt had made many improvements in the manufacture of stockings at Derby.

5628. *Arkwright's first invention was the water-spinning frame* (so named because worked by the power of water), a wonderful piece of machinery, which spins a vast number of threads of any degree of fineness and hardness; leaving to hands merely to feed the machine with cotton, and to join the threads when they happen to break.

5629. We observed under "Spinning" that, in the process of spinning cotton, the thread is formed by two steps; in the first, the flattened roll delivered by the card, called a "sliver," is drawn out and only slightly twisted into what is termed a "roving;" and afterward this roving is stretched to a great length, and sufficiently twisted into a fine cohesive thread. Arkwright's spinning machine consists of two pairs of rollers. The lower roller of each pair is furrowed, or fluted, longitudinally, and the upper one is covered with leather. If there was only one pair of equal rollers, it is clear that a carding of cotton passed between them would be drawn forward by the revolution of the rollers, but it would merely undergo a certain degree of flattening from their action. No sooner, however, has the carding begun to pass through the first pair of rollers than it is received by the second pair, which are made to revolve with a greater velocity than the first pair. By this contrivance the cotton is formed into a kind of riband. It is obvious that this machine by Arkwright is entirely different from the previous methods of spinning, either by the distaff or by the jenny, which was only a modification or multiplication of the common wheel. Spinning by rollers was another idea, which, though perhaps not originating with Arkwright, was first reduced to practice by him, and this was accompanied by other contrivances equally ingenious, by which the process was perfected.

5630. *One of these is the drawing frame,* which was intended, previous to spinning, to straighten and lay at their full length all the fibres of the cotton more perfectly than it had been possible to do by the carding alone, as formerly was practised.

By drawing and doubling, the irregularities of the ribands left by the cylinders are lessened. The united drawings are now passed through a trumpet-shaped funnel, and thence conducted into a tin canister, round the interior of which it coils itself, being still very slightly coherent, and thus formed into a loose spongy thread, called a "roving," a slight twist being also given to it.

Several roving machines have been invented, but the most perfect at present in use is that called the bobbin and fly frame, contrived by Mr Houldsworth. Another excellent invention is Danforth's tube-roving frame.

5631. *The roving is now to be finally twisted* sufficiently, and spun into a thread. This was effected by Arkwright's water-frame, already mentioned.

When these machines of Arkwright were completed, yarns were produced far superior in quality to any before spun in England, as well as lower in price. Weavers could now obtain an unlimited quantity of yarn at a moderate rate; and they could use warps of cotton much cheaper than the linen warps, and fabrics altogether of cotton, rivalling the calicoes of India, could be manufactured at a low price. The consequence was a great demand for them, and a prodigious increase of weavers and manufacturers. Capital was embarked, and a business of vast extent was created; and then also commenced the factory system. The excellent yarn thus produced was first employed with success, when woven into stockings, at Derby; afterward they made proper calicoes, but the Legislature at first prohibited printing these, and afterward laid on a duty; and it was not till 1774 that English cottons were permitted to be made without linen warp.

5632. *After the invention of Arkwright's machinery, Hargreaves' spinning-jennies were still used;* the former was best adapted for spinning twist, a hard and firm thread, to be employed as warp instead of linen, and the latter produced a softer thread, fittest for the weft. These two inventions did not interfere with each other; but by neither of these admirable machines could the finer kinds of yarn be made, since a thread of great tenuity had not strength sufficient to bear the water-frame.

5633. *Another invention, made in 1779, by Samuel Crompton, a weaver at Bolton, enabled manufacturers to spin yarn of the first quality, and gave rise to the fabrication of British muslins.* This machine, from its combining the principles of Arkwright's water-frame and Hargreaves' jenny, was named the *mule*, or *mule-jenny*. Like the former, it had rollers, and like the latter, spindles, to give the twist. This excellent machine has superseded the jenny, and to a considerable extent the water-frame, having subsequently been much improved, and worked by steam. Some of these machines, now at work in Manchester, turn from 1100 to 2200 spindles. Mules have even been made, called *self-acting mules*, that perform their work without the aid of a single spinner, and the only manual labour employed in them is that of children who join the broken threads. Mule-spinning is the least laborious, owing to the slowness with which the machinery moves in making fine threads. A spinner manages two of them at a time; the pair has from 500 to 2000 spindles.

5634. *Another machine for spinning is also now used, called a throstle*, and the qualities of the yarn, or thread, made by the mule and throstle are somewhat different. The mule is generally used for all numbers to thirty, throstles being now seldom used to spin so high as forty. The mule yarn is of a soft and downy nature, and is employed for the weft in coarse goods, and for both warp and weft in finer fabrics. The yarn made by the throstle is smooth and wiery, and is known by the name of *water twist*, from having been first produced by the water-frame. It is used for the warps in heavy cloths, such as fustians, cords, or for making sewing thread. This kind of thread is made with scarcely any manual labour; a large quantity is exported. By means of these various machines several sorts of thread are manufactured, adapted to different purposes; some factories make only one kind, and others several, besides weaving them by power-looms. We may observe that, besides the machines and processes we have mentioned, which are the principal ones, there are a great many others of inferior importance, the description of which would have rendered the leading ideas less easily conceived, and which we have purposely omitted.

5635. *It is usual to describe the degree of fineness of cotton yarn*, or thread, by a certain number, and the method is this: the yarn is made into hanks, each containing 840 yards of yarn, and, according to the number of such hanks which it will require to weigh a pound, so is the number of the yarn; thus, No. 40 denotes a yarn of which 40 hanks weigh a pound. No. 40 may be considered as the staple of cotton yarn.

SECT. IV.—THE WEAVING OF COTTON.

5636. For the general principle of weaving cotton cloth, whether plain, twilled, or figured, we refer to Sect. III., on "Weaving." At first, the common loom was made use of; but the spirit of improvement, which had carried spinning to so high a degree of perfection, was next directed to the weaving department.

5637. In 1785, the Rev. Dr. Edmund Cartwright first invented a loom that was worked by mechanical power instead of the hand, called a *power-loom;* and, although his was imperfect, it was the parent of others, which are improvements, and which are now in use. Horrock's loom is that which is now generally employed; it is constructed entirely of iron, and is a neat, compact, simple machine, moving with great rapidity, and occupying so little space that several hundred may be worked in a single room of a large factory. It appears that the power-loom has several advantages over the hand-loom for some fabrics, not only producing them with greater expedition and at a cheaper rate, but of better quality, the regularity of the machinery being commanded with more certainty than that of human force. But it is chiefly in making cottons and other strong fabrics that they can be used; fine muslins are yet made mostly by hand-looms. At present, there are in England and Scotland above 100,000 power-looms; and it is supposed that there is an equal number, if not greater, of cotton hand-looms.

5638. But, notwithstanding the ingenuity of these several inventions in the manufacture of cotton described above, of which the principal is undoubtedly the spinning machine of Arkwright, yet it must be admitted that we are indebted to the steam-engine for the vast extension to which the cotton manufacture has arrived, being the moving power of all its machinery.

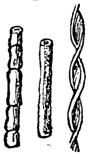
5639. *The printing of cottons* should naturally be next described; but as that depends upon the art of dyeing, and cannot be explained without reference to the latter, we shall reserve the account of calico printing until we have treated of "Dyeing" in general.

SECT. V.—QUALITIES OF GOOD COTTON WOOL.

5640. These are fineness, length of fibre, strength, softness, and equality of the filaments, and freedom from knots and impurities. The more remarkable cotton is for these qualities, and the less waste it suffers in spinning, the higher price it fetches. To judge of its quality, a specimen is pressed and drawn through the fingers, by which its fineness and length may be estimated. The cotton broker and spinner acquire by practice a remarkable delicacy of tact in this way, so that they can pronounce upon the quality, though in the dark. Soft, short filaments are best adapted for spinning into wefts; firm, long, and cylindrical ones are best for making the wiery warps, and lace thread yarn. Formerly, cottons were divided into white and yellow, but improved modes of manufacture have rendered colour of less importance than length of fibre, and the broad distinction, at present, is into "long stapled" and "short stapled."

5641. *With respect to the possibility of distinguishing between the fibres of cotton and of flax*, some very interesting observations have lately been published in the "Transactions of the Royal Society," in a paper by James Thomson, Esq., "On the Mummy Cloth of Egypt." It appears that it has been a matter of doubt whether some of the cloth wrapped round the Egyptian mummies is not of cotton, notwithstanding the general opinion that they are entirely of linen; and that we find no mention among ancient authors that the ancient Egyptians were acquainted with the use of cotton. Nor did it seem easy to determine this question, even upon the actual examination of a variety of specimens of the cloth which had been so employed; some persons pronouncing a piece to be cotton which others contended was linen. It appears, therefore, necessary to discover some test by which the one material could be distinguished from the other when woven into cloth. Simple inspection proves insufficient, nor do chemical means offer any assistance. Mr. Thomson conceived the idea of subjecting the fibres of cotton and of linen to examination by a powerful microscope; this task was performed by the accurate Mr. Bauer, with the assistance of the improved achromatic microscope of Ploessl, of Vienna. Mr. Bauer states that the fibres of flax are cylindrical, and jointed like a cane, as *a*, *fig.* 785; whereas those of cotton, although when in the green or unripe state they are cylindrical, but not jointed, as *b*, when ripe, and in the state in which the cotton is manufactured, are flattened and twisted like a corkscrew, as *c*. This corkscrew form distinguishes the fibres of cotton from those of all other vegetables, and gives an easy and accurate method of determining whether any material is cotton or flax. All the specimens of mummy cloth so examined proved to be of linen.

Fig. 785.



Sect. VI.—COTTON OF VARIOUS COUNTRIES.

5642. Although the cotton plant is the spontaneous production of all the tropical regions, yet the quality of the downy fibre varies in some degree, according to the kind of plant and the country where it grows.

5643. *The American cotton* is reckoned the best, and of this the finest is raised upon a group of low, sandy islands on the coast of Georgia, whence it is termed *sea-island cotton*. It is remarkable for its long staple, the filaments being three times the length of the Indian cotton wool. It has a silky softness, and, when well cleaned, is preferred here to every other for spinning fine yarn; indeed, it is indispensable for the finest, though it is not very white; it is also highly prized by the manufacturers of lace. What is raised upon the seacoast of Georgia is also excellent. The cotton of Berbice, Demerara, Surinam, and Cayenne is of good quality, and long stapled. The chief market for American cotton is Liverpool.

5644. *The West Indies* produce some tolerable cotton, particularly in the Bahamas.

5645. *India* produces every variety, but the ordinary cotton of India is of the herbaceous kind, and an annual: it grows principally in Bengal and the Coromandel coast, where the best cotton goods are manufactured. The cotton of India, in general, is inferior to that of North and South America, being short, though strong in fibre, and the common kind can be spun into fine yarn only by the delicate fingers of the Hindoo women; little of it is imported into England.

5646. *Egyptian cotton* is now cultivated by Mehemet Ali in considerable quantity, and is of excellent quality, but seldom well cleaned.

5647. *The Levant cottons* are, in general, little esteemed, being fit only for coarse yarns and candle-wicks. In the infancy of the cotton manufacture, England received her supply of the raw material from the Mediterranean and the Levant.

5648. *In our cotton mills* the several sorts of cotton are generally mixed together; thus the cheap and short-stapled cottons of India are carded along with some of the longer American cottons, to make them work to the best advantage; and much depends upon the skill of the cotton spinner in making one kind conceal or supply the defects of another.

Sect. VII.—THE COTTON MANUFACTURE IN INDIA.

5649. The Hindoos have not only manufactured cotton cloth from time immemorial, but they have excelled all the nations of the world in the almost incredible perfection of their fabrics; a circumstance the more remarkable, when we consider the extreme simplicity of their apparatus, and their entire want of the ingenious machines by means of which we have endeavoured to rival them. Almost all the varieties of cotton fabrics which we have are made in India in abundance, and the coarse cloths worn by the natives are produced in almost every village; but the finest fabrics of India are the muslins. For this elegant cotton fabric Europe has long been indebted to India, where, through the long lapse of ages, the manufacture has arrived at the utmost perfection. Various kinds of it, originally brought to this country from India, are distinguished by the names of the places where they are made; as jaconet, mullmuls, betelles, tarnatans, tanjeebs, bukes, terridams, doreas, &c., of which we now make imitations.

The exquisite fineness of some of the muslins which have been made in some parts of India would scarcely be credited, were not the fact well attested. Dacca is a place celebrated for its extremely fine muslins, which are not imported, and are scarcely known here. Of their exquisite delicacy, extraordinary accounts are related. Tavernier states that the turbans of some of the rich Mohammedans at the court of Delhi were of so fine muslin that thirty ells did not weigh four ounces; and it is said that some of their broad webs might be drawn through a ring of moderate size, the tissue being so exquisite that it seemed more like the work of insects than of men, and, according to the hyperbole of the East, resembled "the woven wind." A specimen of this manufacture may be seen in the museum of the East India Company. The threads, however, when examined with the microscope, though surpassing in fineness, and spun only by the distaff and spindle, have not the regularity of our machine-made thread. Sir Joseph Banks weighed a portion of the yarn of which this is formed, and found that twenty yards weighed only one grain, and a pound of it would reach 115 miles. In England, yarn has been spun so fine that a pound would extend to 167 miles in length; but such yarn could not be woven here. This extremely fine muslin of Dacca, however, was made only by a few families, and was not permitted to be exported, being intended chiefly for the great and wealthy, at the court of Delhi, under the imperial government. It is said that the art of making it is now in danger of being lost, the orders for it being so few that many of the families who possess the hereditary instruction in the mode of weaving it have desisted, on account of the difficulty they afterward experience in disposing of it. The Dacca muslins are made of a peculiarly fine, long-stapled cotton that grows on the banks of the River Magna. A hundred rupees were the price of a piece of this fine muslin, but some brought to England has cost ten or twelve guineas per yard. In India, they not only excel in the art of weaving white calicoes (calicuts) and muslins of every description, figured as well as plain, but they likewise excel in the flowered and glazed cottons called chintses.

The cotton manufacture of India is not carried on merely in a few large towns; in the cotton districts, formerly, the growth of this material was nearly as general as that of food; everywhere the women spent a portion of their time in spinning, and almost every village where cotton was cultivated contained weavers, and supplied its own inhabitants with the scanty clothing they required.

5650. *The method of fabricating cotton cloth in India is as follows:* The downy fibres being separated from the seeds by fluted rollers of wood, and opened by the stroke of a string fixed to an elastic bow, the cotton is spun by the women; the coarse yarn on a heavy one-thread wheel of teak wood, and of the rudest construction, the finer yarn with a metallic spindle and a distaff. The spinster keeps her fingers dry by the use of a chalky powder; and in this manner are yarns produced, which are finer and far more tenacious than any of the machine-spun yarns of Europe. Then follows the process of warping, which is performed by young persons running nimbly with the bobbins in their hands, and winding the thread round sticks of bamboo fixed in the ground; the warp is then dressed with rice water. The yarn having been thus warped, the weaver's business begins, and his loom is as rude an apparatus as can be imagined. It is thus described by Mills, in his "History of British India:"

The loom (*fig.* 786) consists merely of two bamboo rollers, one for the warp and the other for the web, and a pair of geer, or treadles, for parting the warp. The shuttle performs the double office of shuttle and batten for driving home the weft; and for this purpose is made like a large netting-needle, and of a length somewhat exceeding the breadth of the piece. This apparatus the weaver carries to a tree, under the shade of which he digs a hole large enough to contain his legs and the lower part of the treadles. He then stretches his warp, by fastening his bamboo rollers at a due distance from each other on the turf by wooden pins. The balances of the treadles he fastens to some convenient branch of the tree over his head; two loops underneath the geer, in which he inserts his great toes, serve to move the treadles. Finally, he sheds the warp, draws the weft through it, and afterward strikes it up close to the web. There is not so much as an expedient for rolling up the warp; it is stretched out at the full length of the web, which makes the house of the weaver insufficient to contain him. He is, therefore, generally obliged to work continually in the open air, under the shade of the tamarind or mango tree, and every return of inclement weather interrupts him.

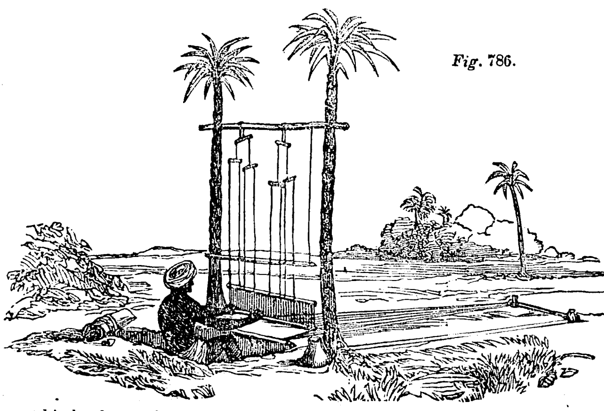


Fig. 786.

In some parts of India, however, as on the banks of the Ganges, the weavers work under the cover of sheds, fixing the geer of their looms to a bamboo in the roof. They size their warp with rice starch. When checkered muslins are wrought, three persons are employed at each loom; one pulls the thread to form the pattern, another twists it, and the third weaves. Spinning and weaving do not disgrace any one; the first is practised even by women of rank, and the weaver takes place of all other mechanics, ranking next to the scribes; yet were he to perform any drudgery of another kind, he would lose caste. A journeyman cotton weaver earns from 2 to 2½ rupees (4*s.* to 5*s.*) a month; a woman spinning coarse yarn can earn only 1⅜*d.* per day. It is truly surprising that, with machinery so rude, this people should produce such delicate fabrics, which, indeed, are scarcely rivalled by those skilled in the mechanical arts. But this is partly explained by the fine sense of touch possessed by the Hindoos, by their patience and gentleness, and by their children having been trained up from their infancy to an art which has been practised by the same family from generation to generation.

5651. *The finest muslins are produced in Bengal.* The Coromandel coast is celebrated for the best calicoes, and Surat for strong and inferior goods of every kind. Condaver furnishes the beautiful handkerchiefs of Masulipatam. The chintses and ginghams are chiefly made at Masulipatam, Madras, and Paliamcotta. The long cloths and pullicots are produced in the presidency of Madras. Besides these, there is an endless variety of fabrics, each district in India producing something peculiar.

5652. *The change that is taking place in the cotton manufactures of India* deserve a few remarks. From what we have already stated in our history of this manufacture, it is seen that no real cotton cloths were made in England previous to the invention of the spinning machines by Arkwright; before that time, all fabrics entirely of cotton, all calicoes, chintses, muslins, &c., were imported from India. Even after the discoveries of Arkwright, Indian cottons were prohibited, not so much for the protection of our cotton, but of our woollen manufacture; and afterward, to encourage calico printing, plain Indian calicoes were admitted under a duty, and were printed in England; but at that time all muslins, which were much worn by ladies, were Indian, and no attempt to imitate them was made until the invention of Crompton's spinning machine, called the mule, which spun, for the first time, cotton yarn sufficiently fine and strong for muslin. From our improvements in machinery, by which cotton thread is spun with such facility, this manufacture in India is now suffering to a great extent. Not only do we undersell Indian cottons in foreign markets, but actually a great quantity of yarn spun by British machinery is sold to the Indian weavers at one half the price which they pay to their own women, notwithstanding the extreme cheapness of their living. The consequences to the natives of India must be extremely injurious, since their hand-loom weavers cannot compete with our steam-engines.

SECT. VIII.—DESCRIPTION OF THE VARIOUS COTTON FABRICS.

5653. It is scarcely possible to convey any adequate idea of the variety of cotton cloths or fabrics that have issued from the loom and the printer, since the commencement of this manufacture to the present time. The pattern cards of Manchester goods sent out to the Continent by the most considerable manufacturers have presented specimens of upward of 1500 different kinds, varying in strength and pattern from the coarse cloths to the finest muslins, and in colour from the richest chints to plain goods, including many figured in the loom. The following descriptions include only those in general use.

5654. *Calico* derives its name from the province of Calicut, in India, where it was chiefly made, and from which it was obtained when originally imported into Europe. It was first brought hither from India in 1631, and was first manufactured in this country about 1772.

5655. *The various kinds of calicoes made in this country are common plain white calico,* usually called cotton cloth; *fents* are remnants, or pieces of this sewed together, and sold as low as 2*d.* or 2½*d.* per yard. *Duck* is a stouter kind; and *double warp* is still stouter. *Calico shirting,* or twine cloth, is a very even made calico, to imitate linen; a superior kind is called *patent twist;* the yarn is closer twisted than in common calico. *Sheeting calico* is a stout fabric, much used as a substitute for linen, and by many persons preferred, particularly in cold weather. *Printed calicoes,* or, as they are called, *prints,* originally made in imitation of those from India, are now manufactured here of an infinity of patterns, of which each year produces some new ones. Vast quantities are exported to every part of the world. See "Calico Printing," Book XVII., Chap. XII.

Calicoes are frequently so full of the dressing, a preparation of lime put in by the manufacturer, to make them of a better colour, that it is difficult to ascertain their quality; it is best, therefore, to choose calico, if possible, free from dressing, and to see that the threads are straight and evenly woven.

5656. *Chints* is a peculiar style of printed calico, in which the figures are of at least five different colours, impressed upon a white or coloured ground. They were originally from India, but are now made here of great beauty.

5657. *Muslins.*—India muslins were first introduced into this country about the year 1670, before which time cambrics and Silesia lawns were used instead, and such fine linens from Flanders and Germany as were brought back in exchange for our woollen manufactures. The manufacture of muslins was attempted at Paisley as early as 1700; but it was not till eighty years afterward that British muslins became a rival to those from India. In 1785 they were much improved, since which period their progress has been rapid beyond all example. In the year 1787, it was computed that not less than 500,000 pieces of muslin, including shawls and handkerchiefs, were annually made in Great Britain. The manufacture has, from that time to the present, continued progressively to increase, and bids fair to become the most lucrative and extensive of any in this country. Glasgow and Paisley, in Scotland, and Bolton, in Lancashire, are the chief seats of this manufacture. It is proper to observe that the Swiss had succeeded, long before us, in the manufacture of muslins at Zurich and St. Gall; yet our inventions in spinning gave us a great advantage over them; these improvements, however, they have lately adopted. Considerable muslin manufactories are established in Germany.

The muslins and other cotton goods of India, notwithstanding the simple and primi tive processes of spinning and weaving by which they are produced, still retain, in some degree, their superiority over those of British manufacture, particularly for durability and retaining their whiteness; but in our finer fabrics the imitation is so close as scarcely to be distinguished from the original; and it requires a practised eye to discriminate between an India and a British mull. Some depend upon the supposed marks of the manufacturer, or the perfume of the cedar boxes in which the India muslins are imported; but these are circumstances easily counterfeited where fraud is intended.

5658. The following are the varieties of muslin now generally known here:

Jaconet is a very general fabric of the lighter description of muslin, very open and soft, but somewhat stouter than the mullmul. The name is supposed to be a corruption of Jaghernout, the district in India where these muslins are chiefly made. It is the thickest of the soft muslins used for dresses, neckcloths, &c.

Nainsook is a still thicker kind of jaconet. These are plain and striped, the stripe running the way of the warp.

Mull muslin is a very thin and soft kind, used for dresses, trimmings, &c. *Swiss mull* is dressed and stiffened.

Scerhand is between nainsook and mull, particularly adapted for dresses, on account of its retaining its clearness after washing.

Buke muslin (erroneously written *book*) is a plain, clear kind of muslin; it is either lawn buke, or stiffened to imitate the French clear lawn; or hard, and more stiffened and dressed; or it is soft, to imitate the India buke. Buke muslin is woven for working in the tambour.

Foundation muslin is a very open-worked muslin, used by dressmakers for stiffening dresses and bonnets. It may be had either in white or black.

Leno is thinner and clearer than buke muslin, and may almost be called a cotton gauze, often employed for window blinds.

Cambric muslin is an imitation of cambric. It is sometimes glazed white, black, and coloured, for linings, and it is also twilled. It is figured, striped, or corded.

Cord and fancy checks are cambric muslins with stripes and cords placed across each other checker-wise, by thick threads being introduced into the warp or weft.

Figured muslins are wrought in the loom of various widths, to imitate those worked in the tambour.

Tamboured muslin must be distinguished from the last, being embroidered by hand on the tambour.

The more open kinds of muslin are best fitted for being ornamented with figures by needle-work on the tambour, the lightness and transparency of the fabric forming a contrast with the closeness of the needle-work. Scotland is the chief seat of the manufacture of tamboured muslins.

Cotton cambric is separated into two kinds: cambrics to be used for dresses, either white or printed, and cambric to be used for the same purposes as French cambric. The first is made in Lancashire, the other at Glasgow.

Scotch Cambric.—One might suppose from the name that this was made of flax; but it is a fine cloth made of cotton to imitate French cambric. From the confused language of shopkeepers, it is necessary to keep in mind that cambric is properly a manufacture from flax, and not from cotton.

Common gauze is a variety of woven texture much used for light purposes. It is formed by the warp being twisted somewhat like a rope during the operation of weaving, by which the cloth acquires a considerable resemblance to lace. The texture of this gauze is always open, flimsy, and transparent, but, from the turning of the warp, it possesses an uncommon degree of strength and tenacity, in proportion to the quantity of materials which it contains. This quality, together with its transparency, fits it for ornamental purposes of various kinds, particularly for flowering or figuring, either with the needle or in the loom.

Nankeen was originally a Chinese manufacture only, and, it is said, derived its agreeable pale salmon-coloured tint from the natural colour of a kind of cotton grown in that country. English nankeen looks equally well at first, and even better, as it is more evenly woven; but it loses its colour, obtained from being dyed, and becomes pale after being several times washed.

5659. *Cotton damasks* are made in imitation of linen damasks, which see; though they answer very well for many ordinary purposes, and are cheap, they are not so durable as linen, nor do they preserve their whiteness except frequently bleached.

Huckabacks and diapers of cotton are made in imitation of the same articles in linen, and are used for the same purpose. They are cheaper, but less durable.

5660. *Cotton ticks* are plain and twilled, in imitation of linen ticks, to which they are inferior. There is also a kind named *union*, composed of linen and cotton.

Gingham is a thin, checkered cotton.

Counterpanes, evidently a corruption of *counter-point*, have little protuberances on the surface, dispersed after a certain pattern.

5661. *Marseilles quilts* are a more elegant kind of bed-quilts, and lighter than common white counterpanes of cotton. This fabric is a double cloth with a third of softer material between, which is kept in its place by the quilting done in the loom.

5662. *Cotton quilting* is made for waistcoat pieces, strong and thick, and much resembling the pattern of diaper.

5663. *Jean* is a twilled cotton, striped as well as white. Satin jeans are of a superior make, wove in the manner of satin, with a smooth, glossy surface, and used much for ladies' shoes.

5664. *Dimity* is a well-known article, made with various stripes, and either twilled or plain; much used for white curtains.

5665. *Fustian* is a species of coarse twilled cotton, but may be considered as a general term which comprehends several varieties of cotton fabrics, as corduroy, jean, velveret, velveteen, thickset, thickset cord, and other stout cloths for men's wearing apparel; from their strength and cheapness, they are very serviceable to agricultural people. It is generally dyed of an olive, leaden, or other colours. Fustians appear to have been first manufactured in Barcelona, and were so named from the Spanish "fuste," strong. They were first brought to this country from Flanders, where they were also made, probably in consequence of the connexion between that country and Spain. They were much in request formerly, though it does not appear that they were made here to any extent until the manufacture was brought over by the religious refugees, several of whom settled in Bolton and Manchester, and gave rise to the cotton manufacture of these places. But the fustians of that time were not made wholly of cotton. Cotton could not then, as we have already stated, be spun in Europe fit for the warp, which was obliged to be of linen, and the weft only was of cotton. Till the inventions of Arkwright furnished water twist for the warp, fustian was a mixed manufacture of linen and cotton. At present it is made entirely of cotton. Fustians are either plain or twilled. Common plain fustain, called *pillow*, is sold as low as 7*d.* a yard; when of a strong twilled texture, and cropped or shorn before dyeing, it is called *barracan* and *moleskin*; when shorn after being dyed, it is called *beaverteen*. These form strong, durable, and cheap materials for clothes for labouring people.

Cantoon is a fustian with a fine cord visible on one side, and a satiny surface of yarns running at right angles to the cords upon the other side. The satiny side is sometimes smoothed by singeing. The stuff is strong, and has a fine aspect.

Corduroy is classed among fustian, but is ribbed or corded, the projecting part having a pile. The best kinds are twilled. It is a strong wear. Cutting or cropping fustians by hand, to give them a corded appearance, is a very laborious and delicate operation; and a machine has been invented which effects the purpose with great precision and despatch; hence the price of these articles has lowered, and a great variety has been introduced.

5666. *Velveteen*, or cotton velvet, is an imitation of velvet in cotton; it is of various colours, and much used for the same purposes as velvet, being much cheaper. *Velveret* and *thickset* are modifications of velvet.

5667. *Cotton handkerchiefs* are made of a vast variety of kinds. Some are printed in imitation of India handkerchiefs, and are called *Malabars*, *bandanas*, &c.; others are spotted in white; *navy blues* and *Monteiths* are dyed all of one colour, and have spots of white, through discharging the colour by a particular process. The manufacture of cotton bandanas, by Messrs. Monteith, of Glasgow, is a remarkable instance of what may be done by mechanical and chemical means combined. A great number of cotton handkerchiefs, dyed of a brilliant Turkey red, are laid upon each other and subjected to a press, and a liquid capable of discharging the colour is let into them through apertures in the press. Such is the expedition of this process, that in ten hours 1600 pieces, of 12 yards each, equal to 19,200 yards, are converted into bandanas by the labour of four workmen.

CHAPTER V.

SILK FABRICS FOR DRESS AND FURNITURE.

SECT. I.—HISTORICAL REMARKS.

5668. Mankind must have been far advanced in civilization and the observation of nature before they discovered a material for clothing in the labours of a caterpillar, and perceived that the little yellow ball which adhered to the leaf of the mulberry tree could be unwound into slender filaments, and these made to form tissues of endless beauty and variety. China, one of those countries in which the arts of life have long arrived at a high degree of perfection, appears to have been the first to make use of silk. We are told that the empresses of that country, many years ago, surrounded by their women, employed their leisure hours in the rearing of silk-worms, and in the weaving of silk tissues and veils; but numerous must have been the experiments and trials made before the thick velvet, the stiff brocade, and the thin gauze could have been formed from this material. From China, or, as it was then called by the Greeks, the country of the *Seres*, this valuable commodity was conveyed into India and Persia; and after the conquest of that empire by Alexander the Great, it was brought into Greece; from thence it was carried to Rome, where, as we are informed by several historians, it was so rare, and deemed of such value, as to be sold for its weight in gold. Vopiscus tells us that the Emperor Aurelian, who died A.D. 275, refused the empress a suit of silk, on account of its high price, although she solicited it with much earnestness. For several centuries the Persian merchants supplied the Roman empire with silk, which was brought overland from China by means of caravans that traversed the vast continent of Asia in 243 days. It is said, indeed, that at that time the raw material was brought from China and woven in manufactories established in Persia, Tyre, and other places of the East.

But, notwithstanding an immense trade in this substance, which was for a series of ages carried on between the Roman and Persian empires, and after the seat of the former was transferred to Constantinople, the nature of the silk-worm and the manner in which the silk was produced remained secret with the Chinese, and was entirely unknown in Europe until the reign of Justinian, A.D. 555. At this time, two Persian monks, who were employed as missionaries in some of the Christian churches already established in India, penetrated into China, where they observed the labours of the silk-worm, and became acquainted with the art of working its productions into a variety of elegant fabrics. On their return to Constantinople, they were encouraged by the emperor to undertake a second journey for the purpose of procuring these wonderful insects themselves. This they effected by conveying, in a hollow cane, a quantity of the eggs, which were afterward hatched; and it is remarkable that these became the progenitors of all the generations of silk-worms since reared in Europe and the western parts of Asia.

Manufactories of silk were soon afterward established, not only at Constantinople, but at Athens, Thebes, Corinth, and other parts of Greece; and for six hundred years these were confined to the territories of the Greeks. Its first diffusion was the consequence of the invasion of Greece by Roger I., king of Sicily, who carried a number of silk weavers to Palermo; and the silks of Sicily are described as having been of great excellence. The Venetians afterward, in consequence of their commerce with the Greek empire, supplied all the west of Europe for several centuries. By degrees this manufacture was introduced into Italy, Spain, and France.

In 1521, the French, under Francis I., being supplied with silk-worms and work-people from Milan, began a silk manufacture at Lyons, which has flourished ever since that time, and the demand for Eastern silk has diminished in consequence. In Spain, the culture and manufacture of silk was introduced at an early period by the Moors; and it was there that silk knit stockings were invented, whence they were brought over to Henry VIII.

5669. *The use of silk in dress was extensively adopted in England by the wealthy soon after the Norman conquest,* but was then confined to occasions of ceremony. The destruction of the city of Antwerp in 1583, by the Duke of Parma, drove a third part of the silk weavers to England, and they laid the foundation of the art in this country. Another political event, the revocation of the Edict of Nantes in 1685, produced a similar effect, and the Spitalfields silk weavers date from that time. But it was the introduction of the throwing machine by Sir Thomas Lombe that completely established the silk weaving in the British dominions.

5670. *Great hopes were at one time entertained that native silk could be produced in England;* but though the silk-worm works very well in this climate, and may be reared for amusement, and silk obtained with great care, yet the necessary food, the white mulberry tree, requires greater warmth than that of our usual summers; hence, all the attempts to raise silk for manufacture have not afforded profitable results. Some have supposed that the animal degenerates here, and lettuce-leaves are a poor succedaneum for the mulberry. If, indeed, by due care, silk could be produced in England in sufficient quantity, still the high price of labour would prevent its culture from becoming a source of profit to the producer. Notwithstanding this, the English manufacture has gone on improving steadily, and affords one of the most remarkable instances where an art, borrowed from other nations, and employing a material of foreign growth, has at length equalled that of the countries from which it was derived.

Of late, several causes have contributed to improve our silk manufactures; one of the principal has been the removal, in 1826, of the prohibition of importing French silks which has compelled our weavers to improve their art, in order to compete with French ingenuity. Indeed, in point of substantial excellence, plain silk manufactured in England is now considered at least equal to that of France; while in all mixed fabrics of silk and wool, silk and cotton, silk and linen, &c., our superiority is admitted by the French themselves. But we do not yet rival our neighbours in ribands, figured gauzes, and light fancy articles. The greater attention paid to the art of designing in Lyons, the consequent better taste of the artists, and the superior brightness and lustre of their colours, give them advantages with which it is difficult to contend.

SECT. II.—FORMATION OF SILK.

5671. *The silk-worm*, which produces the most splendid article of raiment, is an animal not more remarkable for the precious matter which it furnishes for this purpose than for the many forms it assumes. Like many other insects, it goes through four metamorphoses. In its most perfect state, it is a white-coloured moth (*Phalæna Bombyx mori*), which lays a number of small eggs, each about the size of a pin's head, from which, in the warmth of spring, the caterpillars are hatched. No sooner does the worm burst its shell than it begins to eat greedily, its food being the leaves of the mulberry tree, of which there are several species; but the white is preferred. For about thirty days it continues to feed upon them, casting its skin either three or four times. At the end of this period, having attained its full size, it ceases to eat for the remainder of its life, and prepares for one of the metamorphoses which it is to undergo, by spinning a ball of fine silk filaments round itself as a defence from injuries during its chrysalis state, in which it lies dormant like a swaddled mummy, and apparently dead, for fifteen or twenty days. At length it breaks through this covering, and comes abroad provided with wings, antennæ, and feet; in short, a butterfly, as above described, which lives only a few days, lays its eggs, and then dies.

5672. *In our description of the formation of silk*, we shall begin with the hatching of the eggs, which we have just said are deposited by the silk-worm. These are generally about five hundred in number by one insect, and when first deposited are covered with a liquid which glues them to the leaf, cloth, or paper on which the female leaves them: they may be freed from this by dipping them in cold water, and afterward drying them. To preserve the eggs, the temperature should be between 54° and 59°; and when the warmth of spring commences, they should be kept in the cool, not exceeding the above heat, lest they should be hatched before the mulberry leaves come out to supply their food. When required to be hatched, they are laid in a room with a stove, and exposed to a warmth gradually increasing till it reaches 86°, the temperature at which the caterpillar appears, and which takes place in eight or ten days. Previously to this, the eggs should be covered with sheets of paper, pierced with holes about one twelfth of an inch in diameter, having mulberry leaves laid on the top. The young caterpillars instinctively find their way through these holes to come at the leaves, which they instantly begin to devour greedily. The leaves, loaded with worms, are then laid regularly on wicker shelves in a well-aired apartment, which should be kept at a temperature from 68° to 86°. Much care is required in managing the silk-worms; their food should be regularly supplied, and everything about them should be kept perfectly clean; also, the proper ventilation of the room is essential. During each moulting or casting of the skin, the animals fall into a languid state, and eat little; but the appetite revives on acquiring a new skin. The caterpillars indicate the commencement of their spinning silk by ceasing to eat, abandoning the leaves, trying to crawl up on the upright parts, and to conceal themselves in corners. Twigs of heath, broom, or other shrubs are now laid in rows on the shelves, and the little creatures begin to construct on these their coverings of silk, called *cocoons*.

5673. *The material of which the silk is formed is a clammy liquid existing in the body of the worm*, which it ejects through two apertures, and which hardens in the air. The filament is at first double, but is immediately agglutinated into one. This liquid matter may be extracted in a lump from the body of the worm, and drawn out artificially into threads of various diameters. At the commencement of spinning the cocoons, the filaments are thrown about without any regularity, constituting what is called the *floss silk*; but soon the animal spins its thread and winds it about in a very regular manner, forming the cocoon into an egg shape, and about an inch and a quarter in length. This is completed in about three or four days; and the animal within has changed from the state of a caterpillar to that of a chrysalis or aurelia. If the cocoons were suffered to remain about eighteen or twenty days, the next metamorphosis would take place, and the butterfly or moth would burst through the cocoon, breaking the filaments asunder, thus rendering the silk useless. To prevent this, the animals within the cocoons are killed before they are ready to break out, by exposing the cocoons for five days to the sunshine or hot weather, or by placing them in a hot stove, or in tin cases surrounded by the steam of boiling water. A heat of 202° is sufficient to destroy their vitality.

The filaments vary in diameter from $\frac{1}{1800}$ to $\frac{1}{2500}$th of an inch, and the silk from one cocoon weighs about two and a half grains. The colour of the silk is yellow, and though of different shades, there is no necessity for sorting it, as this difference disappears in the subsequent processes for preparing it.

Besides the common silk-worm, there are two other varieties that are partially cultivated; one smaller, and the other larger, rarely attaining the length of three inches. When in its indigenous state in China, the silk-worm performs its transformations and spins its cocoons on the growing leaves of the mulberry trees, from which they are taken; but this silk is not so fine as what is produced in artificial cultivation; and the Chinese bestow great care in attending the whole of the processes. On account of the difficulty of procuring food in sufficient quantity in England from the white mulberry tree, other leaves have been tried: of these, the leaves of the lettuce are most relished by the animals; but though they eat and subsist on them for some time, they then spin but a small quantity of silk.

SECT. III.—MANAGEMENT OF THE SILK TO FORM THREAD.

5674. *To wind off the threads or filaments from the cocoons* would appear, at first sight, to be a very difficult operation, yet it is performed in a very simple manner. The cocoons are thrown into a flat basin of copper filled with water, kept heated by means of a charcoal fire, or by steam. In this the gummy matter with which the fine threads are naturally cemented together is dissolved, which permits the filaments of the cocoons to be drawn off and wound upon a reel. But if each cocoon were to be reeled off separately, the thread would prove so slender as to be unfit for use. To make it sufficiently strong, several are wound off together, adhering by their natural gum, and forming one thread. In order to find the ends of the cocoons, on beginning this process the winder employs a whisk of birch; drawing this through the water, several loose ends of the filaments stick to it, and are thus brought out. To unite them together before they reach the reel on which they are wound, a sufficient number are made to pass through a small hole in an iron plate. The reel is of the common kind. It is reckoned that each cocoon yields on an average about three hundred yards of silk. Two hundred and fifty average-sized cocoons weigh about a pound; and eleven or twelve pounds of cocoons give one pound of reeled silk, the remainder consisting of the weight of the enclosed chrysalis, floss silk, waste, dirt, &c. It has been estimated that a pound of the silk filament, as elaborated by the silk-worm, would measure five hundred miles in length.

5675. What is simply drawn from the cocoons in the above manner by reeling is denominated *raw silk*, and a thread of this may contain from three to thirty filaments, the thread being sometimes composed of several groups, which have first been formed of five or six filaments each, the whole being afterward united into one quantity, the thread being thicker according to the number of filaments. When a sufficient length is reeled, it is taken off the reel, and is called a *skein*.

It frequently happens, in the course of this process, that the delicate filaments break, or that one comes to an end before the rest; in that case the winder must join on another to keep up the number; this is done simply by laying on another filament, as it readily adheres to the rest by means of its natural gum; but it requires great attention and skill to preserve the thread of a uniform size. The reeling off the cocoons is a very important part of the preparation of raw silk, as the evenness of the thread, and the absence of knots or knobs, are points of considerable importance to the manufacturer.

In those countries where silk forms a considerable article of commerce, those who rear the silk-worm do not wind off the cocoons themselves, but sell them to others, who make the reeling off a distinct business. It is in the state of raw silk in skeins that this material is imported from the countries where it is produced, as Italy, Spain, Portugal, Turkey, India, &c.

5676. *The various operations by which raw silk is brought into a state fit for the weaver* are briefly the following: 1. It may be twisted in the single thread of raw silk; it is then called *singles*, and is used for some kinds of weft, as in ribands and common silks. 2. Two or more singles may be twisted together, but not very closely; this is called *tram*, which constitutes the usual weft or shoot of the best woven goods, such as gros de Naples, velvets, flowered silks, &c. 3. *Organzine*, or *hard* silk, which is the strongest and most valuable sort, used for the warp of such goods as have tram for the weft. 4. *Sewings* are compound threads of silk, wound, cleaned, doubled, and thrown, with especial reference to their ultimate use as sewing silk.

5677. *Organzine is used for the warp of the best quality of silk*, and is of the utmost importance to the manufacturer, as none of the principal articles can be fabricated without it; it usually contains from two to four threads of raw silk twisted, and so combined as to be of the greatest strength; for this purpose, each thread of raw silk is twisted separately by a mill, and then two of these are twisted together, forming a thread like a rope. The Italians, from whom we formerly imported silk in the state of organzine, kept the art of forming it, called *throwing*, a profound secret. The throwing of silk was introduced into this country in 1719, by the enterprise and skill of Messrs. Thomas and John Lombe, the latter, who was a good mechanic, having, at the risk of his life, and with wonderful ingenuity, taken a plan secretly of one of these complicated machines in the King of Sardinia's dominion, from which, on his return, he established a similar set of mills in the town of Derby.

Lombe lived only a few years after he obtained his patent, being succeeded by his brother William; but the construction of the mills, and the instruction of the various workmen employed, occupied so much time that the speculation was unprofitable; on which account, the cousin, afterward Sir Thomas Lombe, to whom the property descended, petitioned Parliament for the renewal of the patent. This was refused, but the government granted him the sum of £14,000, upon condition that he should deposite a complete set of all his machinery in the Tower of London, for the inspection of the public.

5678. *The mills for throwing silk* are often of most elaborate construction. Lately they have been remodelled by various ingenious mechanicians upon the cotton throstle plan, driven by steam-engines; and these are incomparably superior to what were formerly used in this country, and still are upon the Continent. The machines which they employ abroad for this purpose are small, and are turned by hand, containing about a dozen spindles each. In consequence of these improvements here, little thrown silk is now imported, that produced at home, chiefly at Derby, being sufficient.

5679. *Marabout* is a peculiar kind of thrown silk, often made of three threads of raw silk. Being white as it comes from the worm, it takes the purest and most delicate shades of colour at once, without the discharge of its gum.

5680. *Floss silk is that portion of waste silk* which is drawn from the cocoons that are reserved for breeding, and from which the moths eat their way out by holes, which, cutting the silk into pieces, renders it impracticable to wind it, together with such cocoons as will not wind off. This silk, when carefully spun by a spinning-wheel, in the manner of flax, is termed *spun silk*, the thread of which is little inferior, for some purposes, to the regular silk which is wound off from the cocoons. It is often made into stockings, which are very durable; also into shawls, handkerchiefs, and other articles.

Sect. IV.—Bleaching and weaving silk, and preparing it for the dyer.

5681. *Raw silk is bleached white* by first immersing it in a solution of good soap in river water. After boiling for two or three hours, the silk is taken out, beaten, and then rinsed in cold water. It is then wrung, dipped in soap and water, and boiled again; after which it is suspended in a kind of stove constructed for the purpose, containing burning sulphur; the fumes from this give the last degree of whiteness to the silk. Were it not for the dearness of spirits of wine, silk might be bleached by it, according to M. Baumé, and thus made to rival the finest specimens from Nankin.

5682. *Silk is woven chiefly by the hand-loom*, as power-looms do not offer the same advantages in the weaving of this material as they do of cotton; from the delicacy of its texture, it is continually giving way, and requiring repair in some part or other; a considerable portion of time is also employed in removing all roughness of the warp, during which the actual weaving must be suspended. The saving of time which a power-loom would give would therefore be small, and ceases to be an object of great importance. Figured silks are now woven by the admirable Jacquard loom; and patterns which formerly required the greatest skill, and the most painful labour, are produced by this machine by weavers of ordinary skill, and with little more labour than that required in weaving plain silks. This loom has been much improved in England.

5683. *Silk is sometimes embossed*, by passing the plain stuff between rollers, the surfaces of which contain the desired pattern, which on one cylinder is raised and on the other sunk, so that the eminences of the one coincide with the depressions in the other. Ribands are frequently embossed in this manner.

5684. *Watering silk* is producing an unequal and peculiar wavy appearance by placing together, lengthwise, one on the other, two pieces of silk, and passing them, thus circumstanced, between two cylindrical metal rollers, one of which is made hollow for the purpose of containing a heated iron in its cavity. The two surfaces of the silk not absolutely coinciding, one part will be subjected to more pressure than another, which gives rise to the peculiar appearance.

5685. *To render silk thread fit to receive the dye*, and also to make it soft and glossy, after the operation of twisting or throwing, it requires to be boiled in soap and water to discharge the gum. After the boiling, it is washed in clear water to discharge the soap, and, when dried, will be found to have lost about one fourth of its weight; at the same time, the silk has acquired that soft texture and glossiness which are the principal beauties of it. In the first instance, the gum gave the only adherence of the fibre to form a thread, but by the twisting the fibres are firmly united, and no longer require any cement. It is also necessary, in order to give a fine dye to the silk, that the gum should be removed, because it would prevent the entrance of the dyeing matter to the centre of the thread, and thus impair the beauty of the colour. If the silk was thus boiled before the twisting, nothing but a fine entangled down, or wool, would be obtained, and it would require spinning, by a similar process to that of cotton, before a thread could be obtained.

5686. *One pound of reeled silk* may be converted into sixteen yards of gros de Naples, and is produced from twelve pounds of cocoons, the produce of the labours of 2800 worms, which have consumed 152 pounds of mulberry leaves.

Sect. V.—Chemical properties of silk.

5687. *The chemical properties of silk are* these: The gum with which the raw silk is coated is soluble in hot water, and the colouring matter, which is a kind of resin, may be dissolved by digestion in alcohol; the silk itself would then be white. This varnish, altogether, amounts to about 23 per cent. of the raw material. The remaining fibrous matter has not been well examined by chemists. Caustic alkalies corrode and dissolve it. Silk is of a very imperishable nature, and has resisted the ordinary causes of putrefaction when buried in a grave. It is a powerful electric, or is capable of being excited so as to give out sparks of electricity when rubbed; it is likewise a non-conductor of electricity, and is therefore always employed in electrical machines. The electricity of silk stockings, when pulled off, has frequently excited surprise.

Sect. VI.—silk of various countries.

5688. *Chinese Silks.*—A large quantity of both raw and wrought silks is annually imported from China. In 1829, it appears from the custom-house, 600,000 pounds' weight of raw China silk came into this country. The silk-worm in China is reared in the greatest quantity in the neighbourhood of Nankin, the more southern provinces being unfavourable to its growth. Sir George Staunton tells us that, in the city of Han-choo-foo, a great number of women are employed, in extensive factories, in the fabrication of flowered and embroidered satins. China silk excels every kind in its brilliant whiteness, the cause of which is not yet understood here.

5689. *The silks brought from Italy* are partly raw and partly wrought. Wrought silks come from Piedmont, Novi, Bergamo, and Bologna, but a part of the silk we have from Italy is thrown. The raw silk of Piedmont is superior to that of France, which is attributed to certain regulations respecting uniformity in the mode of reeling it, which have been imposed by the government of the country at an early period of the silk cultivation; whereas in France every farmer is permitted to reel as he pleases; the consequence of which is, that there is no uniformity among the silks of different cultivators. It has been generally thought that there are some qualities in Italian thrown silk that rendered it superior to our own for certain purposes; but this idea appears not to be very correct, and some of our manufacturers use English thrown silk for all kinds of goods.

5690. *French Silks.*—France possesses a great advantage in her climate of being able to rear the silk-worm, and thus obtain native silk in her southern provinces, not, however, in sufficient abundance to supply all her manufactories. Lyons, the great silk manufacturing city of France, from whence the principal merchants of Paris obtain their silks, furnishes very little from French materials. Its prosperity has suffered much from political revolutions, but it still maintains its superiority over other places, particularly for the richest silks and fancy goods. In the manufacturing texture we equal, if not excel, the French, on account of the superiority of our machinery, but they surpass us in the taste of the patterns of such silks as are figured, which is probably owing mainly to the care which the French government has taken in establishing schools of design. The looms at Lyons for weaving fancy goods have greatly increased in number, while those for plain goods have as much decreased. In plain silks we now equal the French. As good gros de Naples can be bought in Manchester as in Lyons, and as cheap.

5691. Raw silk, of its own growth, is not allowed to be exported from France, and, as some of the Italian states likewise prohibit the exportation of their raw silk, the greater part of what we receive through France is said to be smuggled from Italy; the latter country also supplies to France the greatest part of the organzine silk used there, the Italian being superior to the French.

5692. *The superiority of the French silk weavers in point of design* may be accounted for, if the following relation, given by Dr. Ure, in his "Philosophy of Manufactures," be not too highly coloured:

"Among the weavers of the place, the children, and everybody connected with devising patterns, much attention is devoted to everything any way connected with the beautiful, either in figure or colour. Weavers may be seen, in their holyday leisure, gathering flowers, and grouping them in the most engaging combinations. They are continually suggesting new designs to their employers, and are thus the fruitful source of elegant patterns. There is hardly any considerable house in Lyons in which there is not a partner who owes his place in it to his success as an artist. The town of Lyons is so conscious of the value of such studies, that it contributes 20,000 francs per annum to the government establishment of the school of arts, which takes charge of every youth who shows an aptitude for drawing, or imitative design of any kind applicable to manufactures. Hence all the eminent painters, sculptors, and even botanists and florists of Lyons, become eventually associated with the staple trade, and devote to it their happiest conceptions. In the principal school, that of St. Peter's, there are about one hundred and eighty students, every one of whom receives from the town a gratuitous education in art for five years, comprehending delineations in anatomy, botany, architecture, and loom-pattern drawing. A botanical garden is attached to the school. The government allows 3100 francs a year to the school of Lyons. The school supplies the scholars with everything but the materials, and allows them to reap the benefit of their works. Their professor of painting is a man of distinguished talents, well known to connoisseurs.

"The French manufacturer justly considers that his pattern is the principal element of his success in trade; for the mere handiwork of weaving is a simple affair with the improved Jacquard loom. He therefore visits the school, and picks out the boy who promises, by taste and invention, to suit his purpose the best. He invites him to his home, boards him, and gives him a small salary, to be gradually advanced. One gentleman told Dr. Bowring that he had three such youths in his employment, to the youngest of whom he gave 1000 francs, or £40 per annum. After three or four years, if the young artist's success be remarkable, he may have his salary raised to double or treble that sum; and, when his reputation is once established, he is sure of the offer of a partnership. Such is the general history of many of the schoolboys of Lyons. Even the French weaver, who earns only fifteen or twenty pence a day, prides himself upon his knowledge of design; he will turn over several hundred patterns in his possession, and descant on their several merits, seldom erring far in predicting the success of any new style. By this disposition, the minds of the silk weavers in France become elevated and refined, instead of being stultified in gin-shops, as those of England too frequently are. In flower patterns, the French designs are remarkably free from incongruities, being copied from nature with scientific precision." "There are also weaving schools, containing from sixty to eighty scholars. In these, a pattern being exhibited, they are required to exercise their invention immediately as to the best means of producing the design on a piece of silk goods. The master removes such difficulties as are occasionally encountered, and leads them to the successful accomplishment of their task."

Notwithstanding this agreeable picture, the author just quoted admits that the silk trade of Lyons is extremely fluctuating, being one of orders, and not of stocks; and that unpleasant differences frequently take place between the master manufacturers and the workmen, from the "mania for creating new designs," which proves a serious inconvenience to both masters and men. "In consequence of the low wages and great expense of living at Lyons, many of the weavers betake themselves to arms, and abandon a trade which gives them no prospect of improvement. It appears that there has been a constant depreciation of the wages of silk weaving in France from the year 1810 down to the present time. The average expense of changing each pattern loom is twenty-five francs, and, in general, it falls chiefly on the weaver, rendering him often the victim of ignorance of the state of trade, and of want of taste in the manufacturer." Simond, who visited Lyons in 1817, has described the poverty of the silk weavers resident in and near that city as being more abject than anything within the experience of our own artisans. There, as with us, the manufacture is, in a great degree, domestic, most of the weavers executing their labour in their own dwellings. The abodes of the French weavers are, however, wretched in the extreme; one room, twenty feet square, not unfrequently serving every purpose, both as a dwelling and workshop, for three entire families.

5693. *Much silk is produced in Sicily*, but scarcely any of it comes to England. *Turkey* supplies us with a considerable quantity of raw silk, chiefly Persian, from the borders of the Caspian; this comes by the way of Smyrna. Silk is extensively manufactured in *Switzerland*. Velvets are made in *Prussia*, and even *Russia* is beginning to weave silk. Of late, a good deal of raw silk has been imported from *Bengal*, and this has been regularly improving in quality, so as at present nearly to equal that from Italy. In India, instead of having one annual crop, as in Europe, there are no less than three. From some specimens of *American* silk lately sent over to this country, there appears to be some reason for supposing that, before long, this material may be produced to a considerable extent in that country. The silk-worm and the white mulberry tree thrive in all the states of the Union.

Sect. VII.—Description of the various silk fabrics.

5694. *General Remarks.*—Manufacturers distinguish many hundred varieties of silk fabrics made at home and abroad, and even those made in this country are extremely numerous. Silk being an animal substance, it is capable of readily receiving every possible tinge of colour, and may, consequently, be wrought into tissues of any desired hue. The loom also may be arranged so as to produce, not only all kinds of twills, satins, spots, &c., but the richest and most complicated figures. It would, therefore, be futile to attempt an enumeration of all the fabrics now produced in the foreign and domestic silk manufacture, and we shall notice only some of the principal kinds in use among us.

5695. *Silk Damask.*—This is a twilled fabric, and made in the same manner as the well-known linen damasks used for table-cloths, with flowers and other ornamental patterns formed upon it. Formerly silk damask was much used for dress as well as furniture, but it was too expensive a material to have ever come into common use, and was principally confined to the high born and wealthy of the land; not but that, on occasions of ceremony, persons in the middle ranks sometimes displayed silk damask garments, which were handed down as heirlooms from one generation to another. From its name, it has been supposed that the art of weaving damask came originally from Damascus. Its introduction as a manufacture into England was owing to the French weavers, who took refuge here in the time of Queen Elizabeth.

Damask is employed in furniture, such as hangings, chair and sofa covers, &c. Formerly it was wrought with various colours, and it is so still occasionally on the Continent, which sometimes had a rich effect; at present it is not usual with us to have more than one colour, and richness is produced by the elegance and beauty of the pattern.

The weaving of damask puts into requisition all the skill of the weaver for the production of the elaborate patterns which they sometimes bear. Some of these patterns require upward of 1200 changes of the draw-looms for their completion; but the damask employed at the present day for curtains and similar articles of furniture is generally made of a mixture of silk with flax, cotton, or wool, the warp being of the more costly material.

5696. *Brocade.*—An excessive love of rich and splendid stuffs for dress appears to have been a taste originally Oriental. In China and India it has long been the fashion to ornament silk and muslin with threads of gold and silver. These gradually found their way into Europe, and were imitated and improved upon. Silks which have gold or silver threads, or a mixture of these, are called *brocades*, and were highly esteemed by our ancestors, who paid more regard to the richness and value of the material than to the form of the dress. Taste has so much altered in this respect, that it is only in the writings of the last century we can discover the degree of estimation in which this kind of finery was once held. Pope, in his "Rape of the Lock," and Addison, in "The Spectator," have satirized this taste for finery, which we may perceive proofs of in pictures and ancient wardrobes. The richest brocades appear to have been made in Italy;

a considerable manufactory of them was carried on at Lucca during the thirteenth century. The French government afterward engaged a celebrated mechanician, Vaucausin, to contrive machinery for producing similar fabrics at Lyons, an account of which is published in the Memoirs of the French Academy for 1757.

5697. *In the manufacture of gold brocade*, a silver wire is gilt, drawn out to great fineness, and flattened. This is twisted by a machine round a silk thread dyed of a colour as near as possible to that of the metal. The principal art in preparing these gold threads consists in applying the flattened metallic wire so as just to cover the silk completely without any overlapping, and, consequently, making the whole look like a thread of gold. At Milan they had a secret process by which the exterior side only of the flattened wire was gilt; and the Chinese, more economical, instead of flattened gilt wire, often use slips of gilt paper, which they interweave in their stuffs, and twist upon silk threads; but it is obvious that this can have little durability, and is confined to tapestries, or such stuffs as are not exposed to moisture.

In some brocades the ground is plain silk, and the gold and silver are applied by being worked in flowers or other ornaments; afterward, this name was given to rich silk stuffs which were adorned with worked flowers, without gold or silver; and at present it is the custom to apply the term brocade to various silks, as satins, taffetas, lutestrings, and even to stuffs and grograms, if they are adorned with flowers or other figures. Brocades, into the composition of which metals are admitted, are very liable to become tarnished, particularly silver, or where the gold has not been quite pure. When this has happened, their lustre may sometimes be restored by washing them with a soft brush dipped in warm spirits of wine.

The use of brocades in ordinary dress has long been discontinued, but they are occasionally employed in furniture. So late as 1788, some very elegant pieces were woven in Spitalfields, to be used as chair-seats in Carlton House, which proved that the art had not deteriorated.

Besides the perfect brocade, the Venetians made a kind which they called *damasquète*, which, though it had only half the quantity of gold or silver, looked even richer. The flatted wire was neither wound close together on the silk threads, nor the threads stuck close in the weaving; yet, by passing the stuff between rollers, the tissue, or flower, was made to appear one entire brilliant plate of gold or silver. At Nuremberg, a kind of thread for brocade was made by spinning gilt copper wire on threads of flax.

5698. *Satin* is a glossy silk twill of peculiar description, the soft and lustrous face of which is given by keeping a large proportion, frequently even as many as seven out of every eight threads of the warp, visible. In the manufacture of other silken stuffs, each half of the warp is raised alternately; but, in weaving satin, the workman only raises the fifth or the eighth part of the warp, which, presenting an even, close, and smooth surface, is capable of reflecting the rays of light very entire, and the fabric thus acquires that lustre and brilliancy for which it is so much distinguished; but this is assisted by another process. When first taken out of the loom, satins are somewhat flossy or rough, and they are dressed by being rolled on heated cylinders, which smoothes down the face and imparts to them their brilliant lustre. Satin is always woven with the face downward, the labour of the weaver being thereby abridged, as it is easier to raise the harness with one eighth of every cart than it would be to raise seven eighths.

Satin exhibits, in the highest degree, the beautiful lustre of the material of which it is made; no other article of dress has the same beauty in its shadows and reflected lights; hence it has always been a great favourite with the painter, though difficult to represent. Some satins are quite plain, others are figured, and the latter are often of exquisite beauty. Some of the best description are made in Spitalfields. The Chinese are very fond of satins, and some of their make are brought to this country; they are inferior to those made in Europe, but possess the property of being easily cleaned and bleached; they are sometimes flowered with gold and silver. The Chinese excel in the production of flowered satins, as well as damasks.

5699. *Silk fabrics are sometimes woven quite smooth and plain*, as lutestring, gros de Naples, Persian, Ducape, Levantine, sarsenet, &c., which differ from each other only in their thickness, or the quality of the silk.

5700. *Lutestring* is a plain, stout silk, much used for ladies' dresses. There are many qualities and colours.

5701. *Gros de Naples* is the French name of silk, and means, literally, "thick," or "stout," of Naples; it is very similar to the last, but not so stout, and was formerly imported, but is now made plentifully in Spitalfields: it is plain and figured.

5702. *Persian* is a very thin plain silk, the width about half a yard, used for the lining of bonnets, pelisses, cloaks, &c.: it is of all colours.

5703. *Sarsenet* is somewhat thicker, and made twilled as well as plain: it is used for the same purpose as the last, but sometimes also for dresses.

5704. *Taffeta*, under which term the French manufacturers include lutestring, is a smooth silken stuff, having usually a remarkably wavy lustre, imparted by pressure and heat, with the application of an acidulous fluid to produce the effect called watering.

There are taffetas of all colours, some plain, others striped with gold, silver, silk, &c., others flowered or checkered. The chief consumption of taffeta is in summer dresses for ladies, and a particular kind is used for curtains and other drapery. The Chinese manufacture different sorts of taffeta, among which is a substantial kind adapted for drawers and other kinds of wearing apparel; it is so thick and pliant, that it may be folded and pressed by the hand without receiving any crease or mark, and will retain much of its lustre after washing.

5705. *Tabby* is a coarse kind of taffeta watered by pressure between the rollers of a cylinder, so as to produce the wavy effect already mentioned.

5706. *Tabbinet* is a variety of the former, more delicate in its texture.

5707. *Tabarets*, a stout satin-striped silk, used for furniture, as chair-covers, women's shoes, &c.

5708. *Tobine* is a stout twilled silk, used for dresses: it much resembles the Florentine.

5709. *Levantine* is a stout rich black silk, twilled and very soft, and used for dresses: its face and back show different shades. If the face is blue black, the back will be jet black, and *vice versa*.

5710. *Silk serge* is a twilled silk used mostly by the tailors for lining parts of gentlemen's coats.

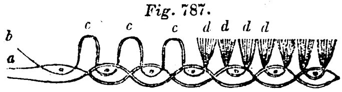
5711. *Paris cord* is a thick rich silk with fine small ribs running across. This was first brought from France, and the genuine has the cord all silk. An imitation is made here, and some of this has the cord of cotton. It is much used in making waistcoats and stocks.

5712. *Armozeen* is a thick plain silk, seldom any other colour than black: it is not much used; sometimes clergymen's gowns are made of it, and it is employed in hatbands, and scarfs at funerals.

5713. *Florentine* is made for waistcoats, and is plain, striped, or ribbed, and figured; when plain it is twilled. It is to be observed that there is another substance called also Florentine, made of worsted for common waistcoats.

5714. *Silk Velvet.*—This is certainly one of the richest of the silken fabrics, and was formerly much more used in dress than at present. Its origin is not known, but it has been made in Europe for centuries; at first, its manufacture was confined to Italy, where, and also at Genoa, it was carried to great perfection. The manufacture then reached France, and afterward Spitalfields. The name comes from the French *vellour*, which is derived from *velu*, covered with hair. Velvet is distinguished from every other kind of cloth by the soft *pile* on its surface, from which its great beauty results. It has this pile in addition to the usual warp and weft which it has in common with plain fabrics. The pile is occasioned by the insertion of short pieces of silk thread doubled under the weft, and which stand upright on its upper surface in such a multitude, and so crowded together, as entirely to conceal the interlacings of the warp and weft. The wood-cut, *fig.* 787, represents on a large scale the disposition of the threads in velvet, which are produced in the loom by means which cannot be explained without going into a detailed description of that machine, and the mode of weaving it, which would be foreign to our present object. The lines *a a* represent the threads of the warp, and the black dots are the threads of the weft crossing them. The line *b* passing into the web, and under the weft, forming loops at top, *c*, *c*, *c*, represents the thread intended to form the pile. As the weaving goes on, these loops, *c*, *c*, *c*, are cut through with a sharp instrument, and, when divided, their cut ends stand out each in the form of a little brush, *d*, *d*, *d*, and, being extremely close, the fibres of the threads separating produce the required pile. The surface of this pile is at first very irregular, but it is made perfectly even by subsequent processes, being cut by machinery, &c. The warp and pile of good velvet are both composed of organzine silk, and its richness depends upon the relative number of its pile threads. The manufacturers are accordingly accustomed to designate velvets of different degrees of richness as velvet of two four, or six threads, according to the number of pile threads which are inserted between each of the dents of the reed. The Spitalfields velvets are so much improved of late, both in fineness and durability of their colours, that they may vie with any foreign velvets. Velvet is sometimes imported from Germany, having the pile of an inferior silk that has been gummed; but, on wearing, this soon looks very ill. The Chinese also manufacture velvets, but they are inferior to the European. Velvet is either *plain*, that is, smooth and uniform, without either stripes or figures, or it is *figured*, or ornamented with various figures, though the ground be the same as the figures; or the velvety figures may be on a satin ground. *Cut velvet* has a ground of a kind of taffeta, or gros de Tours, and the figures velvet. The best manufactures of velvet have been in France, Italy, and Holland; but it is now made in great perfection at Manchester and other parts of England. Velvets that are the worse for wear may be greatly restored by passing a hot iron over the wrong side, while another person holds the velvet tight; this

Fig. 787.



raises the pile; and then the garment should be brushed, or whisked with a fine whisk, such as is sold by the Dutch women.

5715. *Barcelona kerchiefs* are named from Barcelona, in Spain, from which they were originally brought, though now all made in England; they are of four kinds, black, of plain colours, turban checks, and fancy. The black are more for use than show, and measure from twenty-six inches square to seven quarters. The turban checks were originally made for headdresses, and are about twenty inches square.

5716. *Bandana handkerchiefs* are properly Indian, though those made in England in imitation of them are likewise termed Bandana. The black are generally English, though a few come from India. India handkerchiefs not only wear much longer than British, but have the advantage of keeping the colour to the last; but as the patterns are not so elegant as ours, India silk is sometimes imported plain, and printed here. They are twilled and plain.

5717. *Ribands* are a very ancient part of the silk manufacture, and are known to have been used as an ornamental part of dress previous to 1332. They were made in France long before their manufacture was introduced into England; at Lyons it is carried to the greatest perfection. Coventry is the principal seat of the riband manufacture in England, which there gives employment to 10,000 persons; of the looms, about one third are what are called single looms, of a peculiar construction, which weave only one breadth at a time, and are mostly employed in the manufacture of figured ribands; but looms are also constructed, called engine looms, which weave several ribands, from eight to twenty-eight at once. Steam is extensively employed as a moving power. At one time the French ribands excelled ours; but the Coventry weavers have made so marked an improvement in their art since the legalized importation of foreign manufactured silks, that their ribands are, perhaps, nearly equal to those of the French looms; and, notwithstanding this improvement, they are 20 per cent. cheaper than formerly. Ribands are frequently ornamented with what is called a *pearl edge*, which is formed by some of the threads of the weft projecting beyond the rest. The inferior ribands are made of Bengal silk, but the best are made of silk from Italy. Riband is woven in pieces of thirty-six yards each.

Ribands are of various denominations, as satin, sarsenet, lutestring, gauze, taffeta, and pads, all belonging to the plain kind. Figured ribands are classed under the same heads. In some of the French ribands groups and wreaths of flowers are executed with the richness and variety of hand-embroidery. *Clouding* in ribands is produced by a peculiar management in the dyeing. *Galloons* and *doubles* are strong, thick ribands, principally black, used for bindings, shoe-strings, &c. *Ferrets* are coarse, narrow ribands shot with cotton.

5718. *Silk gauze* is an extremely light and transparent fabric, the threads of which are all at some distance from each other. Common gauze is plain, striped, or figured. In the best kind the figure is formed of silk, and a sort with flowers of gold is imported from China; but an inferior sort has the figure composed of magnesia, stuck on with gum. *Lisse gauze* is a plain but superior kind. *Crape lisse gauze* is crimped or craped. *Gossamer* is a very rich gauze used for veils; it is four times as thick and strong as common gauze, though nearly as open in its texture. It may be had four and five quarters wide.

5719. *Italian net* is a strong gauze composed of silk and worsted, and used for dresses; it is of various colours.

5720. *Mousseline de Soie* is a delicate silk fabric about as open as muslin, with a fringe, used for ladies' handkerchiefs, worn round the neck.

5721. *Crape* is a light, transparent stuff, in the manner of gauze, made of raw silk, gummed and twisted in the mill, and woven without dressing; when dyed black, it is much used for mourning. Crapes are either crisped or smooth; the former, being double, expresses the deepest mourning. White crape is used in various dresses. The invention came originally from Bologna; but Lyons has been long celebrated for this manufacture. It is likewise well made at Norwich; and lately a power-loom manufactory has been established at Yarmouth. The peculiar appearance of crisped crape is owing to the operations of dyeing and dressing after it is woven. An additional quantity of gum being added to the silk, the threads are disposed to undo the twist they had received in the mill; and hence the crisped and peculiar appearance. Washing it in hot water shows this; for then the crisping comes out, and it looks like gauze. The warp, and frequently the woof of crape, is usually made of singles; a better kind is made of two-thread tram; this is of a closer texture, and the crisping is superior.

5722. *China crape* is a beautiful variety, remarkably fine in texture and weighty in substance, which is usually dyed in various shades of pink and other gay colours, used in rich dresses.

CHAPTER VI.

FABRICS OF MIXED MATERIALS.

5723. There is a class of fabrics of mixed materials which cannot properly come into those which we have described; these mixtures consist of silk and other materials, or cotton and wool together, or where linen forms a part.

5724. *Bombazin* is a twilled fabric, the warp being silk and the woof worsted. It was first invented in 1575, by the Flemings, who settled in Norwich, and introduced the weaving of fine worsted stuffs. Being gray and black, it was chiefly used for mourning dresses; and it used to be largely exported to Spain and the Spanish Colonies for the dresses of the religious orders. When its manufacture was improved by the worsted yarn being spun by machinery instead of the hand, and dyed of various colours, a great deal of coloured bombazin was made in Norwich, Spitalfields, and other places; but this is not at present much used, the manufacture being almost confined to black.

5725. *Norwich Crape.*—It is difficult to say how this came to be designated a crape, as it is a very different fabric from the usual crapes. It is composed of a silk warp and worsted woof, generally of different colours, or, at least, of different shades. It is of all colours, and is distinguished from bombazin chiefly in not being twilled.

5726. *Poplin* is composed of a warp of silk and weft of worsted, but having more silk in its composition than bombazin. Irish poplins have long been celebrated, and are used for dress in the highest circles. Dublin is the place where they are made of the first quality. Superb patterns have been manufactured for court dresses, in gold and silver, on white, pink, and azure grounds, with flowers, and of every variety of colour; yard, and yard and a half wide.

5727. *Lustre* is a variety of poplin, but less substantial.

5728. *Gros des Indes* is a silk formed by using different shuttles with threads of various substances for the weft, by which a stripe is formed across the web.

5729. *Valentia* has a cotton warp, or a cotton and silk warp for the silk pattern, and the weft is worsted of British wool. There are often imitations of silk patterns from Spitalfields, and form a very showy manufacture: used for waistcoats.

5730. *Toilinette* has a weft of woollen yarn, and the warp of cotton and silk: used for waistcoats.

5731. *Cassinette* is made of a cotton warp, and the woof of very fine wool, or of wool and silk; it differs from valentia and toilinette, having its twill thrown diagonally.

5732. *Swansdown* is made of wool, with a small quantity of silk, for waistcoats; an inferior kind has cotton instead of silk.

5733. *Woollen cord* resembles corduroy, and is cut in the same manner as cotton cord, which is one of the varieties of fustian; but the face is wholly woollen. It has a warp of cotton and weft of woollen. It is strong and warm, and is well adapted for riding.

5734. *Linsey-woolsey* is a homely fabric, formerly much used by women among the working classes, made of thread for warp, and its woof worsted, generally one blue and the other white, or mixed with red.

5735. *Merinoes* are sometimes made of superior wool and silk.

On a few other Materials used occasionally in making Cloth.

The following substances, either actually employed, or proposed, for making cloth, are more interesting as objects of curiosity than as deriving any great importance from their actual value. They are, however, proper to be noticed, since, in this age of invention and speculation, hints of this kind may possibly suggest new and useful applications.

5736. *Several other caterpillars besides the silk-worm spin a kind of silk*, but it does not appear that any successful experiments have been made on them with the view of employing their threads in cloth.

5737. *The short-legged spiders*, also, form balls of silk to enclose their eggs. Some trials have been made with these; but they have all proved inferior in quality to the true silk, or cannot be procured in sufficient quantity to render them an object of attention. Indeed, from the ferocious disposition of these insects, they cannot be kept together in any number, as they fight and destroy each other.

5738. *The pinna marina*, a species of large muscle abundant on the coast of Italy, has the faculty of spinning from its body certain fine, brown threads, resembling silk, by which it fastens its shell firmly to the rocks. These threads, collected, form a remarkably fine kind of silk, of which stockings, gloves, and other articles, in small quantities, are manufactured by the people on those shores. The pinna fastens itself so strongly to the rocks, that the men who are employed in fishing it are obliged to use considerable force to break the tuft of threads by which it is secured, fifteen, twenty, and sometimes thirty feet below the surface of the sea. The threads of this shell have, from very ancient times, been employed in the manufacture of certain fabrics; it was well known to the ancients under the name of *byssus*, and was wrought, in very early times, into gloves and other articles of dress and ornament. It appears that robes were sometimes made of it, since we learn from Procopius that a robe, composed of byssus of the pinna, was presented to the satraps of Armenia by the Roman emperor.

Several beautiful manufactures are wrought with these threads at Palermo. They are, in many places, the chief object of the fishery; and the silk is found to be excellent. The produce of a considerable number of pinnæ is required to make one pair of stockings. The delicacy of the thread is such, that a pair of stockings made of it can be easily contained in a snuffbox of ordinary size, and, notwithstanding their extreme fineness, are found to protect the legs alike from cold and heat. Indeed, stockings of this kind are found too warm for common wear, but are esteemed useful in gouty and rheumatic cases. This great warmth of the byssus, like the similar quality in silk, results, probably, from both being imperfect conductors of heat as well as of electricity. It is not probable that this material will ever be obtained in great abundance, or that it will cease to be a rarity, except in the places of its production. It is never seen in England except in the cabinets of the curious.

5739. *A species of vegetable silk* may be procured, according to M. la Rouverie, from the young branches of the paper mulberry, from the bark of which the Japanese prepare a paper. Cutting the bark while the tree was in sap, and then beating it with mallets and steeping it in water, he obtained a thread from the fibres almost equal to silk in quality; and this was woven into a cloth, whose texture appeared as if formed of that material. The women of Louisiana prepare nets and fringes from fibres obtained, in the same manner, from the mulberry; and the finest of the Otaheitian native cloth is made of the bark of this tree.

5740. *The leaves of the pineapple plant* have been long known to afford a fibre which may be applicable to the purpose of making a species of cloth. The leaves are, in fact, composed of a bundle of these fibres, lying parallel, and extending from the base to the point of the leaf. To prepare these fibres for use, it is only necessary to pass the leaves through a very strong press, or under a heavy hammer, by which they are crushed, and all the juicy matter forced out; this leaves the fibres dry, and resembling a large skein, which, after being rinsed in water and dried, becomes easily separable into a white, glossy material, of considerable strength, resembling flax. This plant grows abundantly in tropical countries with very little cultivation; and it has lately been proposed to employ it in this way.

5741. *Cloth has been manufactured from the wool of the cotton grasses*, by Mr. Helliwel, of Greenhurst Hay, near Todmorden, in Yorkshire. The cloth is russet, very firm, and beautiful; he has also made yarn, for stockings, of the same material. There are two kinds of cotton grass plants; the common or single-headed cotton grass, *Eriophorum vaginatum;* and the narrow-leaved or many-headed cotton grass, *Eriophorum angustifolium*, both perennial plants; but it was from the latter that the cloth and yarn were made. This plant grows wild principally in the highest and most useless land in the kingdom; and it is thought that on Stansfield Common, near Todmorden, there might be from two to three hundred weight produced upon an acre, and that the cost would not exceed 2*d*. to 3*d*. a pound.—*Leeds Mercury.*

5742. *The stalks of nettles* have been used in France for making cloth.

5743. *Hop stalks* have been used in Sweden for making a strong kind of cloth, by a process very similar to that of preparing flax.

5744. *Glass* is a substance that must once have appeared to be one of the most unfit for this purpose; yet the art of spinning this brittle substance into very fine filaments while in a semi-fluid state has suggested the idea of making the threads fine enough to be employed as a material for cloth. Glass is known to be one of the most elastic substances; and so great is the elasticity of its filaments, which can be made thinner than hair, that they bend easily in any direction without breaking. A manufacture has lately been established in which spun glass is employed, together with silk, in forming a splendid kind of brocade, in which the glass threads form the figured pattern. This glass may be made of any colour: when yellow, the threads imitate gold; and when white, they look like silver; and they possess one great advantage, that they can never tarnish nor change colour in any way. Nothing can exceed the beauty and richness of this new kind of cloth, which has already been employed for dress and furniture. Specimens of this beautiful manufacture may be seen at the shop of Williams and Sowerby, Oxford-street, London, who are the patentees.

CHAPTER VII.

LACE.

SECT. I.—HISTORICAL REMARKS.

5745. This delicate and beautiful fabric, which has always been esteemed one of the most ornamental parts of dress, may lay claim to high antiquity, as it appears, from paintings, to have been used for the borders on dresses of Grecian ladies. It has been long made in Italy, and was brought from thence into France and the Netherlands: from the latter country the manufacture came to England, it is supposed, by some refugees, who settled in Bedfordshire and Buckinghamshire, where, in 1640, this art was in a flourishing condition. It had arrived at great perfection in the Netherlands, particularly in Antwerp, Brussels, Mechlin, Louvaine, and other places. Brussels and Mechlin laces were worn by the nobility and persons of high rank in the time of Charles I., Queen Anne, and George I., as is evident from the portraits by Vandyke, Sir Peter Lily, and Sir Godfrey Kneller. These laces were rich and durable, and were worked by hand on the cushion or pillow. In some places in England, lace was also made with great skill, particularly at Honiton in Devonshire, some of which nearly, if not quite, equalled the best Brussels point lace; and, during the war, veils of it were sold for from twenty to one hundred guineas. A very rich dress of lace, worn by her present majesty, has been made lately at Honiton.

Sect. II.—Manufacture of Lace.

5746. *Lace is a delicate net-work, formed of thread, cotton, or silk*, the meshes of which are varied in their figure, being eight sided, six sided, &c. The lace is sometimes ornamented by a thread, called the gimp, much thicker than that of the net, which is worked in among the meshes in the figure of flowers or of various elegant curves; and upon the taste exhibited in these much of the value depends. The various kinds of lace are denominated either from the places where they are manufactured, or from the particular manner of working: such as point net, Brussels or Flanders lace, made in the Netherlands; blond, made in France; pillow or bone lace, and bobbin net, made in this country.

5747. *Not many years ago, all lace was made by hand of flax thread;* and as the process was extremely tedious, particularly when of great width, with complicated patterns worked by the needle, it was very expensive: at present, machinery is also employed to produce it from cotton thread; and the consequence is, that the price of lace has fallen in a degree of which we have scarcely any other example in manufactures.

Lace made by hand, or, as it is called, *pillow lace* and *bone lace*, is worked upon a pillow or cushion, upon which a piece of stiff parchment is stretched, having a number of holes pricked through it to form a pattern of the intended lace. Through these holes pins are stuck into the pillow; and the fine threads, wound upon small bobbins made of ivory or bone, are woven around the pins, and twisted round each other in various ways, to form the required pattern. Bedfordshire, Buckinghamshire, and Northamptonshire were the chief places in England where this kind of lace was made, and it once gave occupation to multitudes of women in their own houses, till the machines deprived them of this occupation; at present still some earn a miserable subsistence by lace-making.

5748. *The imitation of this manufacture by machinery* was first attempted, at the close of the last century, at Nottingham. In 1809, Mr. John Heathcote invented and patented a machine for weaving the real twisted lace, like that made on the pillow: this was called the bobbin machine, and hence the lace produced by it is termed bobbin net. A considerable quantity of lace was made under this patent, which expired in 1824. Immediately a multitude of persons became desirous of embarking in a trade which had so lately yielded a very large profit.

"A temporary prosperity," says Mr. M'Culloch, "shone upon the trade, and numerous individuals, clergymen, lawyers, doctors, and others, readily embarked capital in so tempting a speculation. Prices fell in proportion as production increased; but the demand was immense; and the Nottingham lace-frame became the organ of general supply, rivalling and supplanting, in plain nets, the most finished productions of France and the Netherlands." The inhabitants of Nottingham look back to that period as to a sort of golden age, never equalled before or since. Dr. Ure remarks that "it was no uncommon thing for an artisan to leave his usual calling, and, betaking himself to a lace-frame of which he was part proprietor, realize, by working upon it, 20*s*., 30*s*., nay, even 40*s*. per day. In consequence of such wonderful gains, Nottingham, the birth-place of this new art, with Loughborough and the adjoining villages, became the scene of one epidemic mania." The lace machines are of complicated and difficult construction; but, to execute them, journeymen clock-makers were brought from Birmingham, and afterward master clock-makers set about their manufacture, in consequence of which a great many improvements have been made, and some of them are among the most ingenious pieces of mechanism known. Competition and superabundant supply gradually caused this fever to subside; but the manufacture has now taken its place among those of national importance. From this invention, the most extraordinary changes have taken place in the prices of lace. It has been stated that lace which was sold by Mr. Heathcote for five guineas a yard soon after the taking out of his patent, can now be equalled at 1*s*. 6*d*. a yard; that quillings, a narrow kind of lace, as made by a newly-constructed machine in 1810, and sold at 4*s*. 6*d*. a yard, can now be not only equalled, but excelled, for 1½*d*. a yard; and that a certain width of net, which brought £17 per piece twenty years ago, is now sold for 7*s*. It is calculated that at present above 200,000 persons are employed in the manufacture; one frame can produce 21,490 square yards of bobbin net annually, and about half of what is made in England is exported, in the unembroidered state, chiefly to the Continent; but it appears that, owing to smuggling lace machines out of this country, manufactures are establishing there which bid fair to rival us, if not surpass us, on account of their lower prices of labour from cheaper living. It is remarkable, also, that, as lace machines are now worked by steam power, they do so much more work than the first-invented machines, that the possessors of the latter suffer as much as did the hand lace makers when machines were first invented. There are in this country at present upward of 4000 lace machines, and Messrs. Boden and Morley, of Derby, make 40,000 square yards of lace per week, a quantity that would cover eight acres of land; and it is calculated that the value of the lace manufactured in England in a year exceeds two millions sterling. After the lace comes from the machine, it has to go through the operation of having the loose filaments burned off by singeing in a gas flame.

5749. *The embroidering of lace*, or working figured patterns on it, was at first all done by hand, in the tambour; and many females still earn a miserable pittance by their labour at this work, particularly at Nottingham; but even of this a great deal is now done by machinery that drive a multitude of needles.

When the net is to be embroidered by hand, a pattern is first drawn on paper; if the quantity to be embroidered is considerable, the design is cut on a wooden block, and printed on the net; after being embroidered, the net has next to be bleached, and dyed if required. It is afterward "dressed," or stiffened, by being dipped into a mixture of gum, paste, and water, and stretched on a frame by pins till it is dry.

Sect. III.—Description of the various kinds of lace.

5750. *The most celebrated foreign laces are*, according to Mr. Slater,

Brussels, the most valuable. There are two kinds: *Brussels ground*, having a hexagonal mesh formed by platting and twisting four threads of flax to a perpendicular line of mesh; *Brussels wire*, ground made of silk, meshes partly straight and partly arched. The pattern is worked separately, and set on by the needle.

Mechlin, an hexagonal mesh formed of three flax threads, twisted and platted to a perpendicular line or pillar. The pattern is worked in the net.

Valenciennes, an irregular hexagon, formed of two threads, partly twisted and platted at the top of the mesh. The pattern is worked in the net similar to Mechlin lace.

Lisle, a diamond mesh, formed of two threads platted to a pillar.

Alençon (called blond), hexagon of two threads, twisted similar to Buckingham lace, considered as inferior to any other made on the cushion.

Alençon point, formed of two threads to a pillar, with octagon and square meshes alternately.

5751. *The French nets* made by machinery are,

Single press point, called, when not ornamented, *tulle*, and when ornamented *dentelle*, made of silk, is an inferior net, but attractive from the beautiful manner in which it is stiffened.

Trico Berlin, so called from being invented at Berlin, and the stitch being removed three needles from its place of looping, is fanciful and ornamental in appearance, but not in demand in England.

Fleur de Tulle, made from the warp-lace machine; mesh of two descriptions, which gives a shaded appearance to the net.

Tulle Anglois is double-pressed point lace.

Thread lace of foreign manufacture must be imported in quantities of not less than twelve yards, unless of the value of £2 or upward per yard, or solely for private use; if lace so imported shall be joined or pieced, it is liable to forfeiture. Foreign lace can only be imported into the port of London. No gold or silver lace can be imported, under the penalty of £100. Licenses must be obtained annually for the sale of foreign and British lace.

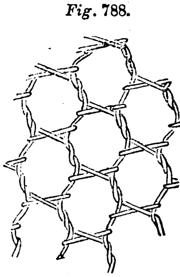
5752. *English laces are*,

A Silk Net in imitation of Blond.—A yard, three inches wide, machine-made, is now sold for 3½*d*., which formerly cost several shillings.

Quilling silk net, slightly stiffened with gum.

Pillow, or Cushion, or Thread Lace.—This is worked on the pillow or cushion, as above described; and, being made of linen thread, is the most durable. No lace will bear repeated washing without injury, except the thread lace; it is, therefore, still preferred by many persons.

Fig. 788.



Piece bobbin net is machine-made lace, of various widths, from 3-8 to 8-4. It resembles in its texture the plainer kinds of pillow-made lace. The threads are entwined together, so as to form perfectly regular six-sided meshes. The wood-cut, *fig.* 788, exhibits, on a magnified scale, the disposition of the threads, which results from the crossing and intertwisting of three, one of which proceeds from above, downward, in a winding direction, as the warp; the two others in a zigzag direction, crossing each other.

The beauty of bobbin net lace depends not only on the quality of the thread, but principally upon the perfectly hexagonal shape of the meshes. This elegant texture possesses all the beauty and regularity of the old Buckingham pillow lace. It is sometimes wrought with a thick thread among the meshes, in various patterns, representing sprigs, flowers, scrolls, wreaths, &c. Since the discovery of a new mode of finishing this lace, it has been made to resemble the most delicate specimens of Mechlin. It is used for veils, borders, edgings, trimmings, &c., and is sold at prices which appear excessively low when compared with its delicate fineness and seemingly elaborate workmanship.

Tatlings and pearls are narrow edging made to sew on to the piece net; the former from a quarter of an inch down to a sixteenth, and the latter from a sixteenth to the narrowest width possible.

Sect. IV.—Gold Lace.

5753. *Gold lace is formed of threads, made by covering yellow silk thread with flattened gold wire;* this thread is covered, being afterward woven into lace or cloth. The gold wire is seldom made entirely of gold, but is, in fact, only silver wire gilt, and the manufacture of it exhibits a striking instance of the ductility of gold, and the extreme thinness to which it can be reduced. To form it, a cylindrical ingot of silver is superficially gilt, and is afterward drawn into wire by passing it through a succession of holes in a steel plate, each one smaller than the other. The fine wire so produced is then flattened by a flatting-mill.

The gold with which the ingot is covered at first is not above the $\frac{1}{400}$ or $\frac{1}{500}$th of an inch, and sometimes not the $\frac{1}{1000}$th of an inch, being thin gold leaf burnished on to the silver. When the ingot has passed through the several holes required to form it into fine wire, Dr. Halley calculated that the thickness of the gold was only the $\frac{1}{134500}$th part of an inch; but by flatting, its surface is much increased, and consequently the gold is still thinner. Reaumur's calculation made its thickness still less, only $\frac{1}{350000}$th part of an inch and yet the gilding is entire; the best microscope does not show the least break.

The flattened gold wire so formed is twisted round a silk thread by means of a curious, complex machine, which causes several of the wires to go round the silk at once so that each wire shall just touch another, the whole forming a complete covering of gold.

CHAPTER VIII.

ELASTIC FABRICS AND WATER-PROOF CLOTH.

5754. *Elastic fabrics* being required for various purposes, such as braces, bandages, &c., several methods have been contrived to produce the quality of elasticity. Certain substances, as coils and springs of steel wire, are of themselves more or less elastic; and modes of weaving have been tried which have produced elasticity to a considerable degree, as may be observed in the stocking manufacture, and particularly the ribbed stockings.

5755. *The most perfectly elastic fabrics* are made by means of India rubber, or caoutchouc. The very great elasticity of this substance, with its other properties, suggested the idea that if it could be liquefied, and formed into threads possessing the same elasticity as at first, it would become a valuable material for elastic cloth; but, as we have stated, in the section on "Materials for Furniture," no means could be devised for some time for effecting this purpose. At length a method was discovered, by a major in the Austrian service, of producing threads from caoutchouc, and weaving them into cloth, without dissolving it. This material is softened by hot water, and pressed into thin laminæ, which are cut by a machine into very thin strips. These strips are then extended till they attain the required degree of slenderness; and they are kept stretched for some days in a cold apartment, till they lose their elasticity and become fixed. The threads are then put into a braiding machine, and covered with another thread of cotton, silk, or worsted, which is wound round them entirely, and afterward they are woven into cloth. When this cloth is finished, it is laid upon a table, and a hot smoothing-iron is passed over it, which restores the elasticity to the caoutchouc. It is necessary, by stretching the threads, to deprive them of their elasticity; for, if they were woven in their elastic state, the cloth would become puckered. When elastic bands, garters, or braces are made, the warp only is made of India rubber. These fabrics were first made at Vienna, whence the inventor removed to Paris, and erected a great factory for them at St. Denys. They are now also made in this country. Of the same material are made elastic belts, elastic stockings for varicose veins, knee-caps for weak knees, bands for sprained ankles or wrists, and other surgical bandages.

Water-proof Cloth.

5756. The inconveniences arising from our clothes being wetted by the rain are so universally felt, that numerous attempts have been made to render cloth impervious to water, or, as it is called, "water-proof." Some fabrics are made of such materials, or of such a texture, that they have this desirable quality, either entirely or to a considerable degree, without any preparation. Skins of most kinds are impermeable to wet, and the real camlets, and even good Scotch plaids, keep out the wet for a long time; but none of the artificial fabrics can be considered as completely water-proof, and skins are not sufficiently pliable nor elegant to be generally used as clothing. The first sort of fabric invented for the purpose of affording a completely water-proof covering appears to have been linen or silk varnished over, and familiarly known by the name of *oil skin;* of this great coats and cloaks have been made, coverings for hats, and other articles of dress. These are efficacious to a certain degree, and are still in use; they are, however, liable to several objections. *Varnished linen,* improperly termed *oiled linen,* soon cracks in folding when much used, and allows the wet to get through. *Oiled silk* is much better, being more pliable, but it is likewise more expensive; cloaks have been made of this so light and thin as to go into the pocket, but their shining appearance is too remarkable, and they were never much used.

5757. *A method employed in France for rendering leather, canvass, linen, &c., water-proof,* deserves insertion, as it may be useful on particular occasions. One hundred gallons of linseed oil are boiled over a gentle fire; to this are added a pound and a half of sugar of lead, and half a pound of very finely-powdered pumice stone. The liquid should be kept boiling until it becomes of such a consistence that, after being mixed with a third part of its weight of pipe-clay, it should be of the thickness of molasses; the whole is then passed through a lawn sieve. Next, ten pounds of pipe-clay are ground in thin glue to the consistence of lard; and to this the above varnish is added gradually, taking care to stir it well all the while with a strong wooden spatula, until it be thoroughly incorporated. A pound and a half of burned umber is now added, together with a pound and a half of white lead ground in oil. To apply this composition, the linen, or other cloth, is stretched over a wooden frame, and the varnish is spread by means of a broad spatula; the frame is now reversed, and the other side covered in the same manner. After remaining a week to dry, the article is taken off for use. This was not intended for ordinary clothing, but for boat cloaks, awnings, covers for carriages, &c. If a very glossy varnish be required, five pounds of the above composition are added to an equal quantity of clear resin, which is heated over the fire until it is dissolved; to this is added two pounds of oil of turpentine, with which some colour has been ground to give it a desirable tint; the whole is then passed through a lawn sieve. This varnish is then laid on with a brush, and, when quite hard, is rubbed over with pumice stone and water, and afterward well washed. Two or three coats of this are applied, letting one dry before another is laid on.

5758. *Cloth lined with oiled silk* has also been tried; but though this is impervious to the wet, yet, as the cloth outside holds much water, this, by evaporation, produces considerable cold, while the varnished lining prevents the insensible perspiration from escaping. Such contrivances may, however, be occasionally useful.

What is most desirable is to give the cloth the same property which we find in the fur of several animals, as the otter, beaver, &c. By this repelling property, water, when thrown upon the animal, rolls off again in drops, without wetting it. The cloth would thus be pervious to the air, or to the perspirable matter; but this degree of perfection does not appear to have been yet completely attained, although the idea has occurred to many persons, and several endeavours have been made to invent a cloth of this kind.

5759. *Cloth and stuffs have been made, in a considerable degree, water-proof* by a wash of the following composition: Dissolve an ounce of isinglass in a pound of soft water, one ounce of alum in two pounds of water, and a quarter of an ounce of soap in one pound of water. When the three solutions are made and strained, mix them together, and simmer them for some time. Brush this mixture over the cloth while hot; when dry, brush it well and give it another coat, all on the reverse side. In two or three days the cloth will be fit for use. Cloth prepared in this way does not prevent the air from penetrating, like India rubber; for lighter fabrics glue and gum arabic are added, and sometimes the stuff is dipped, instead of being brushed over.

5760. *The most complete water-proof cloths* are those made so by means of India rubber, which is extremely elastic, insoluble in water, and impervious to water or air. (See description of caoutchouc, in Book V., Chap. V., "Materials for Furniture.")

5761. *In South America* they take advantage of these properties to make water-proof *ponchos*, or cloaks. The cloth is stretched on a frame, and a layer of the liquid juice, fresh from the tree, is spread upon it, which becomes in a few minutes thick enough to have another cloth applied. Both these cloths are then pressed together, and are thus firmly united, the whole being perfectly impenetrable by water. But although this process is extremely easy in the native country of the caoutchouc plants, where only the juice can be procured in a liquid state, it is but of late that means have been discovered for rendering this material available here for the same purpose.

5762. In 1797, Mr. Johnson took out a patent for rendering cloth water-proof by covering one side with a varnish made by dissolving India rubber in equal quantities of oil of turpentine and spirits of wine. To conceal the varnish, which was laid on the wrong side of the cloth, some substance was sifted over it, such as silk, wool, or flock. The articles made in this manner were called *hydrolaines;* but they do not appear to have answered, as they never came much into use.

5763. *The water-proof cloth* which is most perfect in excluding the wet is that which is prepared according to the process for which Mr. Mackintosh had a patent, now expired, and which was mentioned when describing caoutchouc as a material used in manufactures. In this process the India rubber is dissolved by means of the liquid called naphtha, obtained from coal, and the solution is put between two folds of cloth, as in the ponchos of South America, just mentioned; the cloths are then pressed together, and hung up till this varnish becomes sufficiently solid. This method fully answers the intended purpose, and such cloth is not only used for cloaks and shooting jackets, but for a variety of other purposes, as Dr. Arnott's water beds, nursery aprons, and many other articles to be seen in the shops. Even boats, so light as to be easily carried over land, have been made by stretching this cloth over a wicker-frame; and, as the cloth is impervious to air as well as water, a cushion very convenient for travellers, from its elasticity, is made by blowing up a bag made of it, to which a stop-cock is attached. It may be observed that this cloth can be scoured with a brush and soap and water when it is soiled. Another method of using the India rubber for the same purpose has lately been tried, founded upon the pressing this material into very thin sheets. These are fixed between two thicknesses of cloth, or only on one side.

5764. *All water-proof cloth hitherto made* by varnishing over, or by any other process by which they are rendered impervious to the air as well as to the wet, have the disadvantage of confining the insensible perspiration, the consequence of which is that they soon feel intolerably hot to the wearer, and are, on that account, not only unpleasant, but unhealthy, except worn in such a way as to allow of the external air having free access to the rest of the dress. Such water-proof clothes, therefore, should not be made to fasten close round any part of the body, but be as loose and open as possible when it does not rain: that being attended to, they are found extremely useful in travelling.

5765. *Several cloths, said to be water-proof,* yet pervious to air, have been advertised of late; but as the processes are kept secret, we are not able to pass any opinion on them. One of them is said to be prepared with the powder of Lycopodium, which perhaps may be effectual.

CHAPTER IX.

FURS.

5766. *The term fur includes* the skins of all animals that are covered with an exceedingly soft and fine hair, except those which come under the class of wool. In the northern regions, furs have always been highly esteemed on account of the warmth which they afford as articles of dress; but the most valuable kinds have been chiefly employed to ornament the robes of persons of high rank, and vestiges of their application to this latter purpose are still visible in England, in the state robes of the king, the nobility, judges, &c., which are decorated with the fur of the ermine. This is also traceable in the bordering and other forms belonging to emblazonry in armorial bearings. The fur of the black fox is a princely ornament in the north. It does not appear, however, that furs constituted any part of the distinctive dress worn by the patrician orders of Greece and Rome, and the custom of wearing fur as an ornament is probably derived from the northern parts of Asia and Europe.

5767. *It is remarked in natural history* that the colder the country the finer and warmer are the furs of animals, it being wisely provided in the economy of nature that their clothing should be adapted to the rigours of their situations. The finest furs are, therefore, brought from the colder regions; those of high latitudes are better in quality than those of more temperate climates; thus, the produce of Siberia is superior to that of Russia, and the imports from Canada are preferable to those from the United States. Even during winter the furs of most animals improve both in quality and colour. The principal countries for furs are the solitary wilds of Siberia, and the immeasurable forests of North America: they form the riches of those dreary wastes, which produce nothing else for human use; and their value has tempted men to expose themselves to the utmost hardships of cold and hunger while pursuing the chase amid perpetual frost and snow.

5768. *At present furs are esteemed and worn,* not only in those countries where they are useful as a defence against the severity of the seasons, but as ornaments of dress, according to the caprice of fashion, by the inhabitants of milder climates, as the Southern Russians, Poles, Chinese, Persians, Turks, &c. All these nations, being of Tartar or Sclavonian descent, are said to inherit from their ancestors an attachment to fur clothing. Even under the burning suns of Syria and Egypt, and the mild climes of Bucharia and Independent Tartary, there is also a constant demand for furs, although there exists no physical necessity for them. With us they are used partly for the warmth they afford, as well as for ornament.

5769. Previously to the discovery of the New World, the furs in general demand throughout Europe were procured from the north and north-eastern parts of the Russian empire. The colonization of the countries bordering on Hudson's Bay gave a new turn to the trade in furs, and the cession of Canada by the French occasioned an immense importation of this article; in consequence of which, muffs, tippets, and furred garments, which formerly were only worn by people of quality, or the upper classes of gentry, now adorn the dress of females in a sphere of life which, at no remote period, usually displayed more homely attire.

5770. From the eagerness with which the fur trade has been pursued for many years, and the vast destruction of fur-bearing animals, this material has necessarily become more scarce. The advanced state of geographical science shows that few new countries remain to be explored; and from the indiscriminate slaughter practised by the hunters of Asia and America, and the appropriation to the uses of man of those forests and rivers which have afforded them food and protection, they must continue to decrease, although a supply may long remain in the mountains and uncultivated tracts.

5771. *When skins are merely dried*, being in other respects just as they were taken from the animal, they are denominated *peltries;* and they are properly called *furs* after they have undergone an aluminous process, by which the skin has been converted into a kind of leather. The principal animals from which fur is procured, are the ermine, sable, fox, bear, beaver, martin, otter, squirrel, cat, hare, and rabbit; but there are many other animals more rare which afford a fine fur. That of various amphibious animals, as the seal and beaver, is protected by a coating of long, coarse hair; and when this hair is removed, the short fur appears, which is shaved off for the purpose of covering hats.

5772. *The fur of the ermine* is the most valuable of any, and is well known as forming the lining to the state robes of royalty. This little animal is of the genus mustela (weasel), and resembles the common weasel in its form; it is in length from fourteen to sixteen inches, from the tip of the nose to the end of the tail; the body is from ten to twelve inches long. The change of colour which the ermine experiences in winter in northern climates is a matter of much interest to the physiologist, and of profit in a commercial point of view. In summer its fur is brown, and it is only in winter that this becomes of that softness and snowy whiteness which occasions so high a price to be set upon it. This is effected, not by the loss of the summer coat and the substitution of a new one for the winter, but by the actual change of colour in the existing fur. The extremity of the tail, however, undergoes no change, but remains permanently of a brilliant shining black, the under parts retaining a slight yellowish tinge. When the white fur is made up into dress, the tails are inserted, one to each skin, at regular distances, in *quicunx* order, and the pure white of the skin is thus relieved and set off by the rich black of the tail. The early employment of the fur for such uses occasioned its introduction among the colours of heraldry, where it appears either as the ground of the shield, or in the bearings. The fur is found of the best quality only in the cold regions of Europe and Asia, and the animal lives in hollow trees, river banks, and especially in beech forests; it preys on small birds, is very shy, sleeping during the day, and employing the night in search of food. It is taken by snares and traps, and sometimes shot with blunt arrows. The fur of the old animals is preferred to that of the younger. It is seen, though rarely, in Scotland and in the north of England, where it is called the *white stoat*, but its fur is very inferior to the foreign.

5773. *The fur of the sable* is also very highly prized; it is brownish black, and the darker the more desirable it is. It is finer, softer, and more glossy than that of any other quadruped, except the ermine. The sable is a native of Northern Europe and Siberia, and is also of the genus *mustela.* In the northern parts of Asiatic Russia it is found of the richest quality and darkest colour. In its habits it resembles the ermine, preying on small squirrels and birds, sleeping during the day, and prowling for food during the night. It varies in dimensions from eighteen to twenty inches. It is much used at present for making the well-known articles of dress called *boas.*

5774. *The fitchet weasel* yields a valuable fur, though inferior to the sable.

5775. *Fox-skins* furnish a considerable variety of furs. In the cold countries animals of this species are of all colours, white, gray, blue, iron gray, silver gray, red, variegated, and black. Of these the last is the most valuable, and the first the least; the hair of the white fox is apt to fall off. The blue fox-skins are sought for with avidity, owing to their scarcity, and the black fetch a high price, from their justly-acknowledged beauty, but the red fox of Asia is of a more brilliant colour, and its fur softer and finer, than any other; in China it is highly prized, and is variegated by adding spots of black fur. The silver fox is a rare animal, a native of the woody country below the falls of the Columbia River in North America. It has a long, deep, lead-coloured fur, interminged with long hairs, invariably white at the top, forming a bright, lustrous silver gray; by some it is considered as more beautiful than any other kind of fox.

5776. *A dog* is bred in Norway and Lapland for the sake of its skin, which is covered with a remarkably fine, soft, and glossy fur of a dark brown or black colour, and which is imported for muffs and tippets.

5777. *The martin* affords a valuable fur of various colours; but the part that extends along the spine, being of a deeper and richer brown than the rest, is most esteemed. The martins from Northern Asia and the mountains of Kamtschatka, are much superior to the American, although among the latter are some of great beauty. The fur is much employed in *boas*, and is often dyed for sables.

5778. *The sloth* has an extremely beautiful fur, possessing a high lustre.

5779. *The sea otter of North America* has a very fine, close, soft fur. It abounds in the rivers Columbia and Missouri, and also frequents, in great numbers, the Aleutian and Kurile Islands, between Asia and the northwest coast of America. This fur is jet black in winter, with a silken gloss, and that of the young animal is a beautiful brown. It bears a high price in China, where it was introduced in 1780, when furs had become so scarce in Siberia that the supply was insufficient for the demand in the Asiatic countries. It is not much employed in England, but chiefly exported to the north of Europe.

5780. *The fur seal* affords a skin for which the Chinese give great prices. Such numbers have been killed in the South Shetlands, that they have become almost extinct there.

5781. *The skin of the common seal* is made into leather by being tanned, or it is dressed with the fur on for caps and various articles of dress. Among the northern tribes, these skins afford excellent clothing and coverings for temporary habitations. Hundreds of thousands of these animals are killed every year for their skins and oil on the shores and ice-fields of Newfoundland.

5782. *Perhaps the softest and most delicate fur known* is that which clothes a little animal called the *chinchilla*, about the size of a small squirrel, which inhabits Peru and the northern parts of Chili. The fur was known as an article of commerce, and much prized, shortly after the conquest and occupation of Spanish America; and is mentioned by Father Acosta and Sir John Hawkins; but the habits and character of the animal have been known in this country only very lately. The chinchilla burrows in the ground; and Sir Francis Head, in his journey across the Pampas, found the numerous holes made by them dangerous in riding. Their flesh is remarkably fat, and is much relished by the people, who hunt them with dogs. There are two species; the *chinchilla lanigera*, the largest, is about nine inches in length, much resembling the rabbit; the fur is long, thick, close, woolly, somewhat crisped, grayish, or ash-coloured: the other species is described as smaller, only six inches long, and having the wool still softer. It feeds upon the roots of plants, is extremely gentle and docile, and may be easily tamed and kept in the house. Great numbers of these animals are caught in the countries adjoining the Andes, and sent to traders, who carry them to Buenos Ayres, or to Lima, whence they come to Europe. Captain Beechey lately presented a living specimen to the Zoological Society, and another has been added by Lady Knighton. An entire skin has been deposited in the British Museum.

5783. *The skins of several other animals* are employed as furs, and have various values; as those of the *wolverene*, *racoon*, *genet*, *wolf*, *badger*, *lynx*, *bear*, &c. The furs of the *beaver*, *otter*, *lynx*, and *racoon* are used principally for hats; and the *bear-skins*, among other uses, furnish an excellent material for cavalry caps and other military equipments. The skins of the *buffalo*, of the *Rocky Mountain sheep*, of *various deer*, and of the *antelope* are included in the fur trade. The white furs of the *arctic fox* and *polar bear* are sometimes brought from Greenland, but are not particularly valuable.

Among furs may be classed the *Russian*, *Bucharian*, and *Persian lamb-skins*, the soft, compact, and elastic wool of which is formed naturally into elegant curls or waves, as if pressed close to the skin by art; but when killed immediately after birth, or taken from the mother, they are still more beautiful, and often elegantly marbled with feathered waves, like silk damask. The most prized of the former are the blue, the black, and the silver gray; but of the *unborn* lamb-skins, as they are called, the fine black is the dearest and most esteemed. These are very generally used as an essential part of the dress of thousands among the lower classes in Persia, Russia, Poland, E. Prussia, Hungary, and Bohemia.

5784. *The skins of the rabbit and hare* are likewise dressed as furs, and the hair is employed in hats, &c. The supply would not be equal to the demand were our furriers dependant upon our country for them. Hundreds of thousands of rabbit-skins are annually imported here from Germany and other parts of the northern and middle districts of Europe, where myriads of rabbits are bred for this purpose. The fur of the *Angora rabbit* is excessively long. The prepared skins of the rabbit and hare being as warm as some furs, they are used as bosom comforters by those who are subject to diseases of the lungs.

5785. *The skin of the squirrel* has a delicate fur, which, though small, is sometimes joined together in useful articles.

5786. *As furs are used only in winter dresses, and are necessarily laid up during the summer months*, it becomes of importance to know by what means they may be defended from the ravages of the moth, to which they are particularly liable. The most efficacious preventive, it may be presumed, is that which is adopted by the traders and dealers in furs; and on inquiry being made of several, the answer obtained is, that no dependance is had on any of the strongly-scented substances, as camphor, commonly recommended for effecting the purpose in question. The precaution generally practised is daily to take out and open the furs; and while they are extended to beat the back part or skin very gently with a slender cane or stick; after which the fibres are carefully combed out with a comb adapted to this use. Thus the moths that may have obtained access to the furs are expelled, together with any eggs or larvæ that may have been deposited. The furs also, by this daily exposure to the air, are prevented from contracting any disagreeable musty smell, and are kept clean and sweet. To this we may add that, immediately on leaving them off as a wear, they should be put into boxes or drawers, so perfectly tight that no moths can have access to them, in which case they will be perfectly safe; for it is a vulgar error to suppose that moths or any other insects can come without being bred by others. The place where they are kept should be perfectly dry, and they should be aired frequently, to prevent mildew. Bags of brown paper, or strong linen, perfectly well closed, or even for valuable furs tin cases or boxes, will keep them from moths. Some recommend washing the skin with a solution of corrosive sublimate in spirits of wine; but as this is a strong poison, being a preparation of mercury, its use may be hazardous, although it is employed successfully to keep away insects in collections of butterflies and other objects of natural history.

CHAPTER X.

BLEACHING.

5787. *By bleaching, in general, is understood* the freeing cloths of their natural brown or otherwise coloured tinge, and rendering them perfectly white after coming out of the weaver's hands. Also linen, and other articles already in use, when they have lost much of their original whiteness, and become of a bad colour, are sometimes restored to their purity by bleaching.

SECT. I.—BLEACHING OF LINEN.

5788. The most ancient mode of performing this process, and, indeed, the only one formerly known, consisted in exposing the linen cloth on the grass, where it was subjected to the combined action of frequent wetting, of the air, and the rays of the sun.

5789. *Grass bleaching*, that is, bleaching by the influence of water, air, and sunshine, is now seldom practised in regular bleach-fields, having been superseded by an improved method, to be afterward described; but it is used in some parts, and, indeed, is the most common in many civilized countries. It is supposed to be the least injurious to the texture of cloth; and it is that which at present we are most interested in explaining. The details of the process vary in some respects, according to the nature of the cloth to be bleached; and we shall first describe the mode of bleaching linen.

5790. *Linen, as it comes from the loom,* is charged with the weaver's dressing, which is a paste of flour and water brushed into the yarn, to render the stretching of the warp more easy. To discharge this paste, the web must be steeped in cold water for forty-eight hours, till the paste is decomposed by fermentation, which does not extend to the linen itself. Boiling the linen in water will not answer, since paste is not soluble in boiling water. When the linen is well washed and rinsed after this, it is of a grayish-white colour, although the fibres of which it is composed are naturally very white. To separate the matter that discolours the linen is properly the business of bleaching. This colouring matter is of a resinous nature, insoluble in water, and, from its intimate union or dissemination through the very fibres of the flax, is difficult of separation, even by those substances which have a solvent power over it. *Alkaline lyes*, or solutions of alkali, rendered caustic, have the property of dissolving resins; hence they have been employed as menstrua for this purpose, but alone they are not sufficient. What appears to be a single ultimate fibre of flax in gray linen is composed of a bundle of minute filaments, closely cemented or agglutinated together by the resinous matter. By the application of the lye the potash first acts only upon the resin of the external coating of filaments, by which means they are loosened or separated, and exposed to the farther action of the air; a second boiling in the lye opens another layer, and thus successively, layer after layer, until the whole is divided or opened to the centre. Were the alkaline solution sufficiently strong to force its way at once to the centre, it would act upon the filaments themselves, and destroy the texture of the cloth. The lye, called the "bowking, or bucking," is prepared by dissolving potash in soft water, to which some soap is added. This liquor is heated to about 100°, and poured upon the linen. After the cloth is well down in the lye, it is drawn off, heated a little higher, and again poured upon the cloth. This operation is repeated at intervals, allowing the lye to remain longer each successive time, and moderately increasing the heat for five or six hours. The cloth is then left steeping for three or four hours, when it is taken out and well rinsed. But each filament, after the alkaline process, retains a certain impregnation of colouring matter so intimately united as to resist the farther action of it. This is removed by the slow and gradual influence of the atmosphere and the rays of the sun, which together decompose it.

It is necessary, therefore, to proceed in the following manner: The linen is carried to the field, where it is spread upon the grass, and secured by pins; water is sprinkled on it so as not to allow it to become dry for some hours. After it has lain about half a day, the watering is less frequent, and at night it is left to the full action of the air and dews. On the succeeding days it is watered three or four times a day, if the weather be dry, and it remains on the field till the air seems to have less effect in whitening. It is then brought back to the coppers, and bucked again with a lye somewhat stronger than the last, rinsed, and again spread out in the field, which is called *crofting*. It is thus bucked and watered ten or fifteen times, according to the weather, making the bucking stronger and stronger till about the middle, and then weaker and weaker till about the last.

It must now undergo the process of *souring*, or steeping in some acid liquor. The acid which had generally been used was formed by the fermentation of bran and water, or sometimes sour whey has been used. But sulphuric acid, very much diluted, has been found more convenient, shortening the process considerably, and being not more injurious. The cloths are kept in the souring for five or six days, and sometimes weeks, if it be formed of milk or bran; or only twenty-four hours if sulphuric acid has been used. The use of the acid liquor is to dissolve any earthy or metallic matter either inherent in the cloth, or accidentally communicated to it, or derived from the impurity of the alkaline salts in which it has been boiled. They are then rubbed with soap, more particularly the selvages, as these resist most the action of the air. The cloth is now again bucked, rinsed, watered, and exposed to the air, and these processes are repeated successively till the linen has acquired the necessary whiteness.

5791. The art of bleaching was formerly so little understood in Great Britain, that nearly all the linen manufactured in Scotland was sent to Holland to be bleached; but it has been since practised here with perfect success, and the whole operation of grass bleaching generally requires six months. In India, where bleaching was practised from the earliest time, citric acid, diluted, was used in some places instead of sour milk; but this old method of bleaching required considerable time as well as labour; and the risk of damage and robbery, from the cloth lying so long exposed, demanded much watching, and, consequently, great expense was incurred. By the modern discoveries in chemistry, these inconveniences have been in a great degree obviated, and a new bleaching agent has been introduced, unknown to our forefathers, but capable of giving astonishing rapidity and perfection to this important art. This new agent is called *chlorine*, formerly named oxygenated muriatic acid gas, which possesses the singular property of destroying all vegetable colours.

5792. *Bleaching by Chlorine.*—The gas called chlorine was first discovered by Scheele, a Swedish chemist, in 1774. Its property of destroying colours may be easily exhibited by putting into a vial containing it several slips of wet printed cottons; after remaining a short time they will become entirely white. When this gas is absorbed by water, a liquid is produced, formerly called oxygenated muriatic acid, which possesses the same remarkable property, and this was first noticed by Scheele from its whitening the cork of the vial containing it; but it was Berthollet who suggested its application to the bleaching of cloths, for which it is found so useful, that it brought down the time required for this operation from months to days, and even to hours. Profiting by the suggestions of Berthollet, several scientific persons in England, among whom were Professor Copland, Mr. Watt, and Mr. Henry, made experiments and improvements upon this new agent. Chlorine gas, by itself, was first found extremely difficult to use, from its volatility and the suffocating nature of its odour. This gas was then condensed in water, and afterward potash was mixed with this, which had the effect, in a considerable degree, of lessening its deleterious action upon the lungs. This diminution of action on the lungs does not depend on the chlorine itself being changed, but on the slow extrication of it permitting the gas to be greatly diluted with atmospheric air. The latter process having been invented at Javelle, the liquid obtained the name of *liqueur de Javelle.*

5793. But a discovery made by Mr. Henry, at Manchester, and by Mr. Tennant, of Glasgow, has entirely obviated the inconveniences occasioned by the smell of chlorine, and rendered the process of bleaching scarcely, if at all, injurious to the workmen. In this new process the chlorine is combined with lime, forming *chloride of lime, which possesses the bleaching qualities, with much less of the noxious smell;* and cloths put into a solution of this, diluted in a proper manner, can be bleached with such rapidity, that it is said a bleacher in Lancashire received 1400 pieces of gray muslin on a Tuesday, which, on the Thursday immediately following, were returned bleached to the manufacturers, at the distance of sixteen miles, and they were packed up and sent off on that very day to a foreign market. It may be easily conceived what a saving of time and capital this must occasion. So greatly has bleaching been benefited by the discoveries of modern science, that all the processes are commonly performed in a few days, and at the trivial cost of a half penny per yard on the cloth bleached and finished. The chloride of lime, or *bleaching powder*, is now made for three pence a pound. In using it, the powder is mixed with a sufficient quantity of water, and immersion in a solution of it answers the same purpose as exposing the cloths on the grass and watering. The dry chloride is less liable to decomposition than the liquid, besides being more portable.

In this new process, therefore, the steeping in bleaching liquor is substituted for exposure on the grass, and the bowking in alkaline lye and steeping in a solution of chloride of lime are repeated several times, until the whiteness is sufficient; afterward the cloth is well washed, passed through sulphuric acid diluted, and washed again with soap; and, lastly, is finished by starching, blueing, and calendering.

5794. *The chloride of lime is made on a great scale*, in the north of England, in the following manner: Lime is spread upon the stone floor, or stone shelves, in a closed room, and the chlorine, in the state of gas, is conveyed into the room by a pipe, when a combination takes place between the chlorine and the lime. The chlorine gas is formed in a leaden vessel by mixing equal parts of black oxyde of manganese and salt, and pouring on an equal quantity of sulphuric acid with as much water; the chlorine gas disengages, and from the vessel a leaden pipe leads it to the lime room. In this case, the salt and the black oxyde of manganese are decomposed; the sodium is converted into soda by attracting oxygen from the oxyde of manganese, and that salt, combining with the sulphuric acid, forms sulphate of soda, while the chlorine passes off in the form of a gas.

5795. *Bleaching liquid* is then made by adding one pound of fresh chloride of lime to two gallons and a half of cold water, which probably does not cost the manufacturer above a farthing a gallon.

5796. *The mode in which this bleaching liquor acts* is the following: When water is added to it, this effects its partial decomposition, by lessening the affinity of the chlorine for the lime; hence one half the chlorine leaves the lime, and dissolves in the water; it is therefore ready to act upon the colouring matter of the stuff exposed to it; and, as we have shown that the effect of chlorine is to destroy colour, this is, accordingly, what happens when coloured cloth is immersed in the liquid.

To increase the bleaching power of this fluid, a little acid is sometimes added, which, uniting to the lime, detaches still more chlorine.

Sect. II.—Bleaching wool.

5797. *In the bleaching of wool*, it is necessary first to free it from the natural grease, called yolk, which it contains; and this is done by scouring it with water mixed with stale urine, the ammonia which this contains being sufficient to remove the grease. In the employment of alkaline lyes for this purpose, great caution must be used; for, though wool is insoluble in water, it is capable of being dissolved by a strong alkali. When the expense is not an objection, scouring with soap is practised as preferable. Sulphureous acid, or the vapour produced by burning sulphur, is likewise employed for whitening wool as well as exposure on the grass.

Sect. III.—Bleaching cotton.

5798. *The bleaching of cotton*, in the first instance, being always performed by the manufacturer, does not come within the scope of domestic economy, and therefore need not be treated of here much in detail. When the cotton cloth comes from the loom it is covered with light, hairy filaments, which are singed off by passing the web over a heated copper cylinder. The fibres of cotton are covered with a resinous matter, and with a very small quantity of colouring matter, which are removed by an alkaline lye, or by exposure several times to steam and rinsing in water, previous to bleaching and dyeing. The weaver's dressing has also to be removed; and the bleaching is now generally performed by chloride of lime.

5799. After the bleaching of cotton cloth is completed, to improve its appearance it is usually passed through starch made of wheaten flour, mixed with porcelain clay and calcined gypsum or whiting, by which the cloth is made stiffer, and to exhibit greater substance, apparently, than it proves to have after being washed. The process was originally contrived for the purposes of fraud; and though now too generally understood to deceive many persons, yet the practice ought to be laid aside. The cloth is then dried on cylinders heated by steam, and afterward calendered, folded, and pressed. Dyeing and printing are subsequent processes.

Sect. IV.—Bleaching silk.

5800. *Silk, to be bleached*, must first be deprived of the natural varnish with which the filaments are coated, and to which is ascribed much of its stiffness and elasticity. This varnish is of a resinous nature, and is soluble in alkaline lyes. Soap generally removes it; but, as the matter separated is very fetid, putrid fermentation will take place and injure the silk, if it be not well rinsed in water. Steam is employed in France for this purpose; and, to give silk its complete splendid whiteness, it is necessary also to expose it to the fumes of burning sulphur, to destroy a substance of a yellowish colour with which the European silk is impregnated. The silk intended to be white requires to be more completely scoured than that which is to be dyed.

Sect. V.—Various facts respecting bleaching.

5801. *When linen or calico is discoloured by town washing, by age, or lying out of use*, the best method of restoring the whiteness is by bleaching it in the open air, and exposure on the grass to the dews and winds. There may occur cases, however, where this may be difficult to accomplish, and where a quicker process may be desirable. Here the art of chemistry may assist, and the following directions have been given by an eminent practical chemist. The linen must first be laid for twelve hours in a lye formed of one pound of soda to a gallon of boiling hot soft water; it must then be boiled for half an hour in the same liquid. A mixture must now be made of chloride of lime with eight times its quantity of water, which must be well shaken in a stone jar for three days; then allowed to settle, and, being drawn off clear, the linen must be steeped in it for six and thirty hours, and then washed out in the ordinary manner. This will remove all discoloration.

5802. *To expedite the whitening of linen in ordinary cases*, a little of the same solution of chloride of lime may be put into the water in which the clothes are steeped; but it must be evident that so powerful an agent must be employed with great caution, otherwise it may injure the linen.

5803. *Steam has been employed in bleaching* linen with great success in France. The process was brought from the Levant, and Chaptal first made it known to the public. In the old processes the close texture of linen resists the action of the heat of a common lye, and hence a long succession of lyes, and exposure on the grass, and considerable time were necessary to penetrate the fibres of the linen from stratum to stratum, as we have already shown. In the process of bleaching by steam these difficulties are removed. The high temperature of the steam swells up the fibres of the cloth, and then the alkali used with it penetrates into the cloth and seizes on the colouring matter. But steam alone does not bleach. After the cloth has been some time exposed to its action, it is to be taken out and immersed in chloride of lime, and afterward exposed a few days on the grass, by which the oxygen of the atmosphere rapidly carries off the colouring matter. If a yellow tint still remain, a second vapour bath and a second immersion in the chloride of lime will be sufficient to give the necessary whiteness.

5804. *The horse-chestnut* has been employed in France and Switzerland for the purpose of bleaching yarn; and it is recommended in the Mem. of the Soc. of Berne, vol. ii., p. 2, as capable of extensive use in whitening not only flax and hemp, but silk and wool. It contains an astringent saponaceous juice, which is obtained by peeling the nuts, and grinding or rasping them. They are then mixed with hot rain or running water, in the proportion of twenty nuts to ten or twelve quarts of water. Wove caps and stockings were milled in this water, and took the dip extremely well. It is supposed that if the meal of the chestnuts could be made into cakes or balls, it would answer the purpose of soap in washing and fulling. The sediment, after infusion, loses its bitter taste, and becomes good food for fowls, mixed with bran.

CHAPTER XI.

DYEING.

SECT. I.—GENERAL AND HISTORICAL REMARKS.

5805. The art of dyeing, though now seldom much practised in domestic economy, is too intimately connected with clothing and dress to be omitted. We shall, therefore, explain its general principles, and give directions for what is likely to be attempted by individuals not professed dyers; at the same time, we may observe that, in London and other places where there are professed dyers, it is better to employ them for valuable articles of dress or furniture, as it is not worth while to risk spoiling them. Their charge depends partly upon the colour, some colours being more expensive than others.

5806. *In all ages brilliant colours have excited admiration*; and even the uncultivated savage has evinced a passion for the beautiful and bright hues to be found in the feathers of birds and other natural objects. The origin of dyeing, or producing colours by artificial means, is of great antiquity; for Moses speaks of stuffs dyed blue, and purple, and scarlet, and of sheep-skins dyed red. Among the Greeks, dyeing appears not to have been much practised; the woollen clothes usually worn by them were of the natural colour of the sheep; but the wealthy preferred coloured dresses, of which scarlet was much esteemed; still more highly valued was purple, which was the distinguishing mark of the greatest dignities, being reserved for princes only. The most famous of their purple dyes was that called Tyrian, which is said to have been drawn from a certain shell-fish, a species of murex, common on the shores of the Mediterranean; but the quantity of purple juice afforded by this animal is exceedingly small, and, consequently, garments stained with it were of great price. The Romans were equally severe in restricting the use of purple to the highest rank; and it does not appear that the number of their dyes and dyed colours was considerable, although coloured dresses were not rare among them.

5807. The art of dyeing slowly improved in modern times, until the application of chemistry, by throwing on it peculiar light, has of late advanced it to a degree of perfection formerly unknown.

SECT. II.—THEORY OF DYEING.

5808. *Among the various substances capable of communicating colours to cloths of different kinds, very few have so strong an affinity for them as to answer of themselves the purposes of dyeing.* When we except indigo, the dyer is scarcely possessed of a dye-stuff that yields of itself a good colour sufficiently permanent to deserve the name of a dye, as they are almost all capable of being discharged by washing the cloth in water. This difficulty, which at first sight might appear insurmountable, has been obviated by a very ingenious contrivance. It has been found that, by first immersing the material to be dyed in certain substances, dyes, that without this preparation would be fugitive, become permanent, and cannot be discharged by washing. These substances, therefore, become a bond of union between the cloth and the dye-stuff, and have received the name of *mordants.* The principle appears not to be altogether of modern invention, but to have been known to the Egyptians and other nations of antiquity.

5809. *The nature of mordants is thus explained* by Dr. Thomson of Glasgow:

"The term mordant is applied by dyers to certain substances with which the cloth to be dyed must be impregnated, otherwise the colouring matters would not adhere to the cloth, but would be removed by washing. Thus, the red colour given to cotton by madder would not be fixed, unless the cloth was previously steeped in a solution of salt of alumina. It has been ascertained that the cloth has the property of decomposing the salt of alumina, and of combining with, and retaining, a portion of alumina. The red colouring principle of the madder has an affinity for this alumina, and combines with it; the consequence is, that the alumina, being firmly retained by the cloth, and the colouring matter by the alumina, the dye becomes fast, or cannot be removed by washing the cloth with water, even by the assistance of soap, though simple water is sufficient to remove the red colouring matter from the cloth, unless the alum mordant has been previously applied. The term *mordant* (from the Latin word *mordere*, 'to bite') was applied to these substances by the old French writers on dyeing, from a notion entertained by them that the action of the mordants was mechanical; that they were of a corrosive or biting nature, and served merely to open pores in the fibres of the cloth, into which the colouring matter might insinuate itself; and after the inaccuracy of this notion was discovered, and the real use of mordants ascertained, the term was still continued, as sufficiently appropriate, or, rather, as a proper name, without any allusion to its original signification."

5810. *Mordants not only render the dye permanent, but they have also a considerable influence on the colour.* The same colouring matter produces very different dyes, according as the mordant is changed. Suppose, for instance, that the colouring matter is cochineal; if we use the aluminous mordant, the cloth will acquire a crimson colour; but the oxyde of iron produces with it a black. In dyeing, it is not only necessary to procure a mordant that has a sufficiently strong affinity for the colouring matter and the cloth, and a dyeing substance which possesses the wished-for colour in perfection, but we must procure a mordant and a colouring matter of such natures that, when combined together, they shall form the desired colour. It is therefore evident that we can produce several colours with one dye-stuff, provided we can have a sufficient number of mordants; hence the selection and management of mordants are the chief arts of the dyer.

5811. *Mordants are generally composed of* earths, metallic oxydes, tannic acid, or all of these. Of earthy mordants, the most important and generally used is alumina, either in the state of common alum, or of acetate of alumina. Alum is a triple salt, composed of sulphuric acid, alumina, and potash; acetate of alumina consists of the acetic acid and alumina, and answers better than alum for a mordant. Almost all the metallic oxydes have an affinity for cloth, but only two of them are much used as mordants, viz., the oxydes of tin and of iron. The oxyde of tin is employed in the state of nitro-muriate (now called proto-chloride) and acetate of tin; it is a very valuable mordant, which enables the moderns greatly to surpass the ancients in the lustre of their colours; by its means alone, scarlet, the brightest of all colours, is produced. Tannic acid has also a strong affinity for cloth, and is principally obtained from nut galls and sumach. Oil is sometimes used as a mordant in dyeing cotton and linen.

5812. *Acetate of alumina is made* by a double decomposition of alum and sugar of lead (acetate of lead), but the proportions of each vary much, according to circumstances, and probably to the fancy of the colour mixer.

It is more particularly important that cloth of any kind that is to be dyed should first be rendered white, otherwise the colour of the fabric will interfere with that of the dyeing materials, and the result will be uncertain.

Sect. III.—PRACTICE OF DYEING.

Subsect. 1.—*General Observations.*

5813. *Colours may be divided into simple and compound.* The simple colours are blue, red, and yellow, and cannot be produced by the mixing together of different colours. Compound colours may be produced by the mixing together various colours, in different proportions. Thus, purple is formed by mixing red and blue; green, by mixing blue and yellow; orange, by mixing red and yellow; and the various shades of these depend upon the proportions of the colours so mixed. Some of the compound colours are produced most conveniently by the use of a single dye, yet most of them may likewise be formed by mixing several.

5814. *What is termed giving a ground in dyeing*, is communicating one colour to a stuff, with the intention of applying another upon it, and thus producing a compound colour. When it is found necessary to pass stuffs several times through the same liquor, each particular operation is called a *dip.*

It is important in dyeing that the water should be pure. The earthy salts existing in some water, and rendering it hard, are very liable to affect the colours, and prevent them from combining with the cloth. Water that is muddy, or that contains putrid substances, is also unfit: in short, water that possesses any qualities that can be distinguished by the taste should not be used.

5815. *The substances commonly dyed* are either animal, as wool, silk, hair, leather, and skins; or vegetable, as cotton, flax, or hemp. Great differences exist between the affinities for colouring matter possessed by these different substances, so that a process which succeeds perfectly in dyeing wool may fail when applied to cotton. Wool has generally the strongest affinity for colour; silk and other animal substances come next, cotton next, and hemp and flax last.

SUBSECT. 2.—*Dyeing Wool.*

5816. *Wool, previous to being dyed,* requires to be cleansed by scouring; it is dyed either in the fleece, or after it is spun into thread or worsted, or when it is manufactured into cloth. For forming cloths of mixed colours the wool is dyed before it is spun. It takes up more colouring matter in the state of the fleece than when made into thread, and less when woven into cloth; but the latter varies in this respect, according to its quality.

SUBSECT. 3.—*Dyeing Silk.*

5817. The raw silk of Europe is found to combine more readily with the colouring matter, and to receive a more permanent colour, when dyed in its natural state with its resinous varnish on, than after it has been deprived of it by scouring and whitening: the white China silk has a lustre superior to the European, and is therefore preferred for dyeing. The preparation by aluming, as a mordant, is very important in dyeing silk: the solution of alum must be cold; if the liquor is employed hot, the lustre is apt to be impaired. The colours used in dyeing silk are very delicate; they must therefore be dried quickly, and not be long exposed to the action of the air, that there may be no risk of change; on this account, drying stoves are used.

SUBSECT. 4.—*Dyeing Cotton.*

5818. *Cotton, before it is dyed,* requires to be well scoured by an alkaline lye, and afterward washed in a stream of water, and dried; but in some cases, as in dyeing Turkey red, the unbleached cotton is preferred, as producing a more permanent colour. Aluming and galling are the next preliminary processes in the dyeing of cotton stuffs; after which it is dipped in the dye.

SUBSECT. 5.—*Dyeing Blue Colours.*

5819. The only colouring matters employed in dyeing blue are woad and indigo. *Woad* is a plant cultivated in this kingdom, and even grows wild in some parts of England. *Indigo* is a blue powder extracted from a species of plant which is cultivated for that purpose in the East and West Indies. The indigo plant contains a green fecula, which, while in the green state, is soluble in water; but it attracts oxygen greedily from the atmosphere, in consequence of which it assumes a blue colour, and then becomes insoluble. The use of indigo as a dye appears to have been long known in India, from whence it was first brought to Europe by the Dutch. It is an extremely valuable material for this art, as it has a strong affinity for wool, silk, cotton, and linen; and every kind of cloth may be dyed with it without the assistance of any mordant whatever, the colour thus induced being, at the same time, very permanent. There are two methods of applying indigo in dyeing; one is in a state of solution in sulphuric acid, or sulphate of indigo. With this wool and silk are often dyed blue, but it can scarcely be applied to cotton and linen, because the affinity of these substances for it is not great enough to enable them readily to decompose the sulphate. The colour given by sulphate of indigo is exceedingly beautiful, and is known by the name of *Saxon blue.* One part of indigo is dissolved in four parts of concentrated sulphuric acid; to the solution is added one part of dry carbonate of potash, and then this is diluted with eight times its weight of water. The cloth must be boiled in a solution containing five parts of alum and three of tartar for every thirty-two parts of cloth. It is then thrown into a water bath containing a greater or smaller portion of the diluted sulphate of indigo, according to the shade which the cloth is intended to receive. In this bath it must boil till it has acquired the desired colour. The alum and tartar do not act as mordants, but facilitate the decomposition of the sulphate of indigo.

5820. *The other method of using indigo* is to deprive it of oxygen, to which it owes its blue colour, and thus reduce it to the state of green fecula, and then to dissolve it in water by means of alkalies or alkaline earths, which, in that state, act upon it very readily. If, therefore, indigo, lime, and green sulphate of iron be mixed together in water, the indigo gradually loses its blue colour, becomes green, and is dissolved. This solution is used for dyeing cotton and linen. Another method is to mix the indigo in water, with certain vegetable substances, which readily undergo fermentation; during which the indigo is deprived of its oxygen, and dissolved by means of quicklime or alkali. This process is employed in dyeing wool and silk.

5821. *In dyeing wool blue,* woad and bran are used as vegetable ferments, and lime as the solvent of the green base of the indigo. Woad contains a colouring matter precisely similar to that of indigo, only in smaller quantity. When the cloth is taken out of the vat it is of a green colour; but it soon becomes blue by absorbing oxygen. It is then carefully washed.

5822. *Silk is dyed light blue* by a ferment of six parts of indigo, six of potash, and one of madder. To dye it dark blue, it must previously receive a ground colour; *archil* is used for this purpose.

Cotton and linen are dyed blue by a solution of one part indigo, one part green sulphate of iron, and two parts of quicklime.

Subsect. 6.—*Dyeing Yellow Colours.*

5823. *The principal colouring matters for dyeing yellow* are weld, fustic, quercitron bark, and anatto. *Weld* (*Resiola luteola*) is a plant that grows commonly in this country. *Fustic* is the wood of a large tree that grows in the West Indies. *Quercitron* is a tree of North America, the bark of which contains colouring matter. *Anatto* is a kind of paste made from the berries of a plant that grows in America. Yellow colouring matters have too weak an affinity for cloth to produce permanent colours without the use of mordants. The mordant most usually employed for this purpose is alum, or acetate of alumina. Where very fine yellows are wanted, oxyde of tin is used. The yellow dyed by fustic is more permanent, but not so beautiful as that given by weld or quercitron. A good drab colour is given by fustic, when the mordant is oxyde of iron. Weld and quercitron bark give nearly the same colour, and the latter is the cheapest.

5824. *Wool may be dyed yellow* as follows: Boil it for an hour or more with about one sixth its weight of alum; then, without rinsing it, plunge it into a bath of warm water containing as much quercitron bark as equals the weight of alum employed as a mordant. The cloth is to be repeatedly turned in the boiling liquid, till it has acquired the intended colour. To deepen the colour, a quantity of clean, powdered chalk, equal to the hundredth part of the weight of the cloth, is to be stirred in, and the boiling to be continued for eight or ten minutes longer. For very bright golden yellows the oxyde of tin must be used as a mordant. If a greenish yellow is wished for, some tartar may be added to the dye. The addition of a little cochineal will give an orange.

5825. *Silk may be dyed yellow* by weld or quercitron bark. The proportion should be from one to two parts of bark to twelve parts of silk, according to the shade wanted. The bark, tied up in a bag, should be put into the water cold, and the temperature then raised to 100°, when the silk, previously alumed, should be dipped in, and continued till it has acquired the proper colour. Chalk or pearlash will deepen the tint.

5826. *Cotton and linen are dyed yellow* by a mordant of acetate of alumina, prepared by dissolving one part of acetate of lead and three parts alum in a sufficient quantity of water. The cloth is to be soaked for two hours in this solution, heated to 100°, wrung out and dried, and the soaking and drying may be repeated; it is then barely wetted with lime-water, and dried. If the colour is wished to be very bright and durable, the soaking and wetting with lime-water should be repeated several times; the lime makes the dye more permanent. The dyeing bath is prepared by putting quercitron bark into cold water with the cloth, then bringing this gradually to a boiling heat; but after this the cloth must only remain a few minutes, lest the colour should acquire a shade of brown.

5827. *Nankeen yellow* is dyed by a solution of red sulphate of iron, which is combined with the cloth by carbonate of potash.

Subsect. 7.—*Dyeing Red Colours.*

5828. The colouring matters employed for dyeing red are, kermes, cochineal, archil, madder, carthamus, Brazil wood, lac, and logwood. *Kermes* is a species of insect, but it does not afford so fine a colour as cochineal, another insect: both are from America *Cochineal* is the most precious of all our dyeing drugs, affording the scarlet crimson, and from it the finest carmine is obtained. It was found in use among the Mexicans, on the discovery of America; and it was the beauty of its colour, as displayed in their furniture, ornaments, and cotton cloth, which attracted attention. At first it was supposed to be the seed of a plant, appearing in the form of small shrivelled grains; but it was afterward ascertained to be a species of insect, called *Coccus cacti*, from its feeding on the *Cactus opientia*, or prickly pear. The best cochineal is still produced in Mexico, though it is now also brought from India and other tropical countries. There are varieties of the insect, affording dyes of different qualities; the dye from the wild insect is inferior to what is produced from those kept in gardens. Lately it has been introduced into Cadiz, where it is reared in a botanic garden, and promises to succeed in that climate. *Archil* is a paste made by pounding a species of lichen (*Rocella tinctoria*) with stale urine. *Madder* is the root of a well-known plant. *Carthamus* is a flower cultivated in Spain and the Levant. It contains two colouring matters; one yellow, which is soluble in water; the other red, which is insoluble in water, but soluble in alkaline carbonates, as carbonate of soda. *Brazil wood* is the wood of a tree growing in America and the West Indies: its decoction is a fine red colour. *Lac* is the production of an Indian insect. The decoction of it gives a fine deep crimson. *Logwood*, called also Campeachy wood, grows in the Bay of Campeachy and Jamaica. It gives out a colour to alcohol, but sparingly to water. None of the red colouring matters have so strong an affinity for cloth as to form a dye without a mordant.

5829. *Wool may be dyed red* by any of these, according to the shade required. Cochineal gives the brightest crimson; the best mordant is nitro-muriate of tin (chloride of tin). Scarlet is a compound of crimson and yellow; and, to produce a bright scarlet, the cloth must first be dyed yellow by means of any of the yellow dyes, and then plunged into a bath of cochineal with tartar and nitro-muriate of tin (chloride of tin). For common crimsons, alum is used as a mordant, and the dye cochineal; or, if pale crimson, a little madder may be added to some cochineal.

5830. *Silk is dyed red* with cochineal, carthamus, or Brazil wood; madder is not bright enough. Archil is used when the colour is to be lilac. Silk cannot be dyed a full scarlet; but a colour approaching to it may be given by first impregnating the silk with murio-sulphate of tin, and afterward dyeing it in a bath composed of four parts cochineal and four of quercitron. Crimson may be given by cochineal alone; and poppy and rose by an alkaline solution of carthamus, to which lemon juice has been added.

5831. *Cotton and linen are dyed red* with madder. The colour is called Turkey red, because first brought from the Levant. It was introduced into Glasgow in 1810, by a Frenchman, M. Papillon, and that city has ever since been famous for dyeing that colour. The cloth is first impregnated with oil, then with galls, and, lastly, with alum; it is then boiled for an hour in a decoction of madder, and plunged into a lye of soda to heighten the colour. The application of the mordant is difficult, but the colour produced is permanent. Cotton may be dyed scarlet by means of murio-sulphate of tin, cochineal, and quercitron bark, but the colour is fading.

SUBSECT. 8.—*Dyeing Black Colours.*

5832. *The substances employed to give a black colour to cloth* are red oxyde of iron and tan, which have a strong affinity for each other. Logwood is used as an auxiliary, as it adds to the fulness of the black. Cloth, before it receives a black colour, is usually dyed blue, to render the black more agreeable. If the cloth be coarse, sometimes a brown from walnut peels is substituted.

5833. *Wool is dyed black* as follows: It is boiled for two hours in a decoction of nut galls, and afterward kept for two hours in a bath of logwood and sulphate of iron, at a scalding, but not a boiling heat. During the operation it must be frequently exposed to the air, because the protoxyde of iron, of which the sulphate is composed, must be converted into sesqui-oxyde, by absorbing oxygen, before the cloth can acquire a proper colour. The common proportions are five parts of galls, five of sulphate of iron, and thirty of logwood, for every hundred of cloth.

5834. *Silk is dyed black* in the same manner.

5835. *Cotton and linen* are not easily dyed a full black. The cloth dyed blue is steeped for twenty-four hours in a decoction of nut galls, and then put into a bath prepared of acetate of iron, wrung out and dried, and the process is continued till the colour is deep enough.

SUBSECT. 9.—*Dyeing Brown Colours.*

5836. *Brown is, in fact, a compound colour*, although it may be given by a single process, by means of several dye-stuffs, as walnut peels, the root of the walnut tree, birch bark, sumach, &c. These substances, containing tannin, which is a mordant as well as colouring matter, produce a permanent dye by simply boiling the cloth with them.

SUBSECT. 10.—*Dyeing Compound Colours.*

5837. *Compound colours, as green, purple, orange*, and an infinity of shades and mixtures of these, some of which have received particular names, are produced by dyeing the cloth first one colour, and then another, to produce the required tint.

5838. *Green*, being composed of blue and yellow, the wool, silk, or linen is first dyed blue, and then yellow, by any of the processes described above. When sulphate of indigo is used, all the ingredients are mixed together, which produces *Saxon green*. Other shades, as *pea green, grass green, sea green*, &c., are produced by employing various proportions of yellow and blue dyes, according to the experience and taste of the dyer.

5839. *Purple* is blue and red, and comprises lilac and violet, which are different shades of it. Wool is first dyed blue, and then scarlet, in the usual manner. By mixing cochineal with sulphate of indigo, the process may be performed at once. Silk is dyed first crimson by means of cochineal, and then dipped into the indigo bath. Cotton and linen are first dyed blue, then galled, and dyed by oxyde of iron.

5840. *Orange*, consisting of red and yellow, is produced by a scarlet or a crimson, and then dyeing yellow. Carthamus gives to silk an orange.

5841. *Olive* is obtained by adding blue to the above, or by a blue, yellow, and madder bath.

5842. *Cinnamon colour* is given by dyeing with slight madder colour before the orange. Silk receives this colour by logwood, Brazil wood, and fustic, mixed; cotton and linen by weld and madder.

5843. *Grays, drabs*, and *browns*, of various shades, are produced by dyeing with oxyde of iron, and then yellow with quercitron or sumach.

CHAPTER XII.

CALICO PRINTING.

5844. *Historical Remarks.*—Cotton cloths are seldom dyed of one uniform colour, except for linings; but when used in dresses for the female sex, drapery of beds and windows, the coverings of furniture, and similar purposes, they are ornamented with figures of various kinds printed in colours; and the endless variety of patterns which are printed on white cotton and muslin give to these fabrics a rich and elegant effect. The natives of India, as they were the first manufacturers of cotton cloth, so they were the first who stained or painted them with various ornaments. Herodotus speaks of a nation on the borders of the Caspian who painted figures of animals on their linen garments with a vegetable dye, which were so durable that they would not wash out; and Strabo speaks in praise of the beautiful flowered cottons of India, which, from the stationary condition of the people of that country for thousands of years, were probably nearly the same as what are made use of there at present. From Pliny's description of the mode in which the Egyptians practised the art of staining their linen cloths by the use of mordants, it is evident that an art analogous to calico printing was well known to the ancients, although less perfect than it has become since by the application of modern chemistry.

5845. Calico printing by means of blocks has long been practised in Asia Minor, Turkey, and all over the East. It is said to have commenced in London in 1676, and was much encouraged and improved in consequence of the government having prohibited, in 1700, the importation of the cheap and beautiful prints of India, Persia, and China, with the view of protecting the woollen and silk manufactures. In order to procure an imitation of the Indian chintses, plain calico was brought over, and printed in England. Parliament then passed a law, in 1701, prohibiting the wear of any printed or dyed calicoes; this confined the printers to the printing of linen, and put a stop to calico printing for ten years. Afterward the printing of cloths made of cotton and linen together was permitted, on paying a duty of sixpence a yard; and subsequently these prohibitions were entirely removed. Calico printing has since been moved from the vicinity of London to Lancashire, where the greatest improvements have been made.

5846. *As the art of calico printing depends, in a great measure, upon that of dyeing*, we must refer the reader to our chapter on that subject; but we shall at present say a few words that may assist in connecting these sister arts. We stated that certain substances will of themselves, when applied to cloth of any kind, produce a permanent colour, or dye, such as will bear washing without being removed; but these substances are few in number. The majority of dyeing materials require, to render them fixed, that the cloth shall first be imbued with some other material that has an affinity both for the cloth and for the dye-stuff. This is called the *mordant*, which acts as a bond of union between the cloth and the dye. The first kind of colours is sometimes termed *substantive* colours, and the latter *adjective*.

5847. *Calico printing consists* in impregnating those parts only of the cloth which are to receive the colour with a mordant, and then dyeing it as usual with some dye-stuff. The dye attaches itself firmly only to that part of the cloth which has received the mordant. The whole surface of the cotton is, indeed, more or less tinged, but by washing and bleaching it, all the unmordanted parts lose their colour, while those which have received the mordant retain it. Let us suppose that a piece of white cotton is to receive red stripes; all the parts where the stripes are to appear are pencilled, or otherwise marked with a solution of acetate of alumina; after that the cloth is dyed in the usual manner with madder. When taken out of the dyeing vessel it is all of a red colour, but by washing and bleaching the madder disappears, leaving every part of the cloth white, except where the stripes were impregnated with the acetate of alumina, which remains red. In the same manner may yellow stripes be given to cloth, by substituting quercitron bark, weld, &c., for madder.

5848. *A few examples of the manner in which various colours are given to calicoes* may be mentioned. 1. One of the most common colours on cotton prints is a kind of nankeen yellow, of various shades, down to a deep yellowish brown, or drab: to produce it, the pattern is printed with acetate of iron, the cloth is then plunged into the potash lye. 2. For yellow, the block is covered with acetate of alumina, and the cloth dyed with quercitron bark. 3. Red is communicated by the same mordant, the dye being madder. 4. Lilac brown and blackish brown have a mordant of acetate of iron, and a dye of madder. 5. Dove colour and drab are done with acetate of iron and quercitron bark. When several colours are to appear in the same print, methods like the following are used: If cloth is dyed with quercitron bark, and then printed with several blocks, that which has acetate of alumina will give a yellow, the block which has acetate of iron will give olive or drab, and that which has a mixture of these two mordants will give olive green.

If the cloth be dyed with madder, the block with acetate of alumina will give red, acetate of iron will give brown or black, and the mixture of these will give purple. Indigo, as in dyeing, is the only colour that can be applied at present, so as to be permanent, without a mordant.

5849. *The mordants are applied to the cloth* either by a pencil, or more frequently by means of wooden blocks, on which the pattern is cut in such a manner as to project in relief. When these blocks are applied, care must be taken that no part of the mordant with which they are covered spread to that part of the cloth which is to be left white, otherwise all the distinctness and elegance of the print will be destroyed. It is necessary, therefore, that the mordants should be of such a degree of consistence that they will not spread to those parts of the cloth beyond the intended pattern on the surface of the block; this is effected by thickening them with starch or gum before they are put upon the block. It is usual to mix some colouring matter with the mordant, in order to render the impression visible; but it must be some substance that may be removed by the same process as the mordant itself. Sometimes two mordants are mixed together, and much of the science and skill of the calico printer depends upon his knowledge of the properties of the various mordants and their action upon colouring matters, so as to render the latter fixed and beautiful.

5850. *Few dye-stuffs are used by calico printers,* and they are chiefly indigo, madder, and quercitron bark, or weld; various tints being produced by the mixture of these and the use of the various mordants.

5851. *Previous to the printing, the cloth as it comes from the loom is prepared* by dressing, which consists in passing the cloth very rapidly over a cylinder of copper heated intensely, or over a broad flame of gas. It is next steeped for twenty-four hours in a weak alkaline lye, and then boiled in a solution of potash, which is termed *ashing*, and afterward well washed. It is next subjected to the process called *souring*, which consists in immersing the cloth in water containing a twenty-fifth part of sulphuric acid. Singeing and calendering are rendered particularly necessary where the printing is by blocks, in order to render the surface smooth to receive a good impression.

5852. *Inventing and drawing patterns for calico printing* employ artists of a peculiar class, who are continually engaged in this business, and the variety produced is immense, to satisfy the perpetual changes produced by fashion. Hitherto our artists have been inferior to those of France and Germany, where the arts of ornamental design have been paid more attention to; but now that there is a national establishment for teaching design as applied to manufactures, it is to be hoped that we will no longer be reproached with inferiority. The designs, when finished, are cut on wooden blocks, or engraved on copper, according to the kind of printing.

5853. *The blocks by which the mordants are applied* are usually made of wood, but sometimes the pattern is cut out of thick plates of brass or copper, fixed firmly to the wood. The printer takes the block into his hand, and presses it down firmly upon the cloth, taking care to be very accurate, applying it regularly, and to keep the pattern uniform and properly joined. Sometimes, instead of printing from the wooden blocks, stereotype casts are made from the blocks, and these are used for printing. When several colours are required, so many blocks are prepared, each to print the separate colours; when a small quantity of one colour is introduced, that is often added by a hair pencil.

5854. *What is called resist work* is another mode of conducting the process, the reverse of what has been described. The pattern is then printed on the cloth with a paste which *resists* the dye colour, when the goods are immersed in the dye vat, so that the grounds only are dyed, the pattern remaining white. This process is practised in cases where the ground is intended to be blue.

5855. *Discharge work* is another variety of calico printing. Here the cloth is first dyed uniformly with some vegetable colour, as Brazil wood; it is next dyed black with an iron colour. The cloth is then washed and calendered, when it will appear uniformly black; but, in order to produce a pattern, this is printed with a peculiar solution of tin, which has the effect of discharging the iron black dye, and rendering the crimson colour of the Brazil wood visible.

5856. *Another method consists* in printing upon Turkey red, or any dyed colour, some powerful acid, and then immersing the cloth in a solution of chloride of lime. Neither of these agents, singly, affects the colour; but those parts which have received the acid, on being plunged in chloride of lime, are speedily deprived of their dye, and made white by the acid of the liberated chlorine. An addition to this invention was made by Mr. James Thomson, near Clitheroe: the acid was combined with some mordant, or metallic oxyde, capable, after the dyed colour was removed, of having imparted to it some other colour. This laid the foundation of that series of processes in which the chromic acid and its combinations have since been employed with such great success.

We have mentioned the original method of printing calicoes by means of blocks, which is still practised to a certain extent; but of late many great improvements have been made in all parts of the processes, and particularly in that of printing.

5857. *To produce more delicate patterns than could be produced by wooden blocks,* copper plates were engraved, and calicoes printed by the usual process of copper-plate printing; but the mode of printing by these was tedious, as well as that by block; in each the patterns had to be applied 448 times in a single piece of calico that was twenty-eight yards in length.

5858. *The grand improvement in the art was the invention of cylinder printing*, in 1785. In this the pattern is engraved upon the surface of cylinder, which is covered with the proper colours, is rolled over the cloth, producing an impression in a rapid manner, and much more accurately than by blocks or plates. The detailed description of this process we extract from Mr. Baines's excellent work "On the Cotton Manufacture." A polished copper cylinder, several feet in length (according to the width of the piece to be printed), is engraved with a pattern round its whole circumference, and from end to end. It is then placed horizontally in a press, and, as it revolves, the lower part of the circumference passes through the colouring matter, which is again removed from the surface of the cylinder, except the engraved pattern, by an elastic steel blade, placed in contact with the cylinder, and reduced to so fine and straight an edge as to take off the colour without scratching the copper. The colour being thus left only in the engraved pattern, the piece of calico or muslin is drawn tightly over the cylinder, which revolves in the same direction, and prints the cloth. After the piece is printed, it passes over several metallic boxes, heated by steam, which dry it. A piece of cloth may thus be printed and dried in one or two minutes, which, by the old method, would have required the application of the blocks 448 times: nor is this all; two, three, four, and even five cylinders may be used at the same time in one press, each cylinder having engraved upon it a different portion of the pattern, and being supplied with a different colour. The piece passes over them successively, and receives the entire pattern almost in the same moment. To produce the same effect by hand-block printing would have required 896, 1344, 1792, and 2240 applications of the blocks, according as two, three, four, or five cylinders may have been employed. The saving of labour, therefore, is immense; one of the cylinder printing machines, attended by a man and a boy, is actually capable of producing as much work as could be turned out by one hundred block printers and as many boys. In consequence of the wonderful facility given to the operation, three fourths of all the prints executed in this country are printed by the cylinder machine. But the course of improvement did not stop here. These cylinders can be multiplied to an extraordinary degree by the process for multiplying copper plates for printing, an invention usually ascribed to Mr. Perkins, but which, Mr. Baines states, had been practised in Manchester some years before he came from America.

5859. *Another kind of cylinders for calico printing consists of* cylinders of wood, which have pieces of brass let into the wood, and projecting above the surface an eighth of an inch.

5860. *Calico printing requires* that the conductors should be acquainted with chemistry, since many of the processes depend essentially upon chemical laws, and the knowledge of these leads to improvements in this complicated art. In large establishments, therefore, there are always some persons who have studied this branch of science.

5861. *The large print-works of Lancashire* are among the most interesting manufactories that can be visited. The bleaching, the block printing, the cylinder printing, the dyeing, the designs of patterns, the engraving of blocks and cylinders, and the preparation of colours frequently all go on within the same enclosure, and form a splendid exhibition of the application of science and mechanics to the arts. Some of these print-works employ some thousands of work-people, while the order and cleanliness of the works impress the visiters with agreeable surprise.

5862. *Linen is seldom printed like calico*, because the latter is cheaper, and printed linens are not so beautiful, the material possessing less affinity for colouring matters.

5863. *The printing of silks, fine woollen stuffs*, such as merinoes, mousseline de laine, &c., or stuffs of silk and wool, is conducted upon the same general principles as the printing of cottons; but all the former require very different and complicated processes.

CHAPTER XIII.

CALENDERING.

5864. Calendering is a process by which all accidental wrinkles and creases are removed from various kinds of silks, stuffs, calicoes, and linens, and their surfaces rendered smooth and uniform. Calicoes are always calendered previous to printing, to make the threads flat. The high polish which certain goods require was formerly effected by rubbing the cloth with a smooth flint stone, but it is now performed by calendering, or passing the cloth between two rollers, one of which is made to move slower than the other. Some of these rollers are made of cast iron, and hollow, so that heaters can be introduced, which are useful in some kinds of goods. Calendering is also used for pressing certain stuffs previous to packing. It is likewise used by the scourers and dyers after their several operations; but calendering is a particular branch of business, and this process is seldom, if ever, performed in private families.

5865. *A glazing* upon some articles is sometimes produced by the old process of rubbing a smooth, hard substance on them, as a polished flint, and, to render the gloss more complete, a little bleached wax is rubbed on the cloth previously.

BOOK XVIII.

DETAILS RESPECTING VARIOUS ARTICLES OF DRESS.

CHAPTER I.

TAILOR, MANTUA-MAKER, AND MILLINER.

5866. These are the persons to whose taste and judgment the fashion or cut of most dresses are intrusted, and, therefore, of whose importance it would be absurd to entertain any doubt. But we have already stated that we do not intend to touch upon the subject of costume, or the forms of dress, which, indeed, among us, are continually varying; and the few observations we have to make upon the details of dress will be confined to those which concern convenience or economy.

5867. Less than a century ago, it was a usual custom for gentlemen to purchase their cloths and velvets, and to employ a tailor to make them into clothes; and at that time much more practical knowledge of the material must have been necessary than at present, when a partial union has taken place between the trades of the tailor and the woollen draper. The present usual practice is to place confidence in the former, that he will employ only good materials. Putting the whole into his hands has, however, the bad effect that it has become extremely difficult to judge of the correctness of his charges, or the extent of his profits. Without proposing to alter the system of executing this business, we may observe that some acquaintance with the manufacturer's qualities and prices of materials may form some check on exorbitant charges, and serve at once the cause of economy and morality. The same remarks may be applied to the dresses of ladies; but ladies have some advantage over men, in being more generally familiar with the details of dress; nevertheless, where fashionable dress-makers are employed, there is likewise some reason for looking into the details of their accounts, and the qualities of the materials. The subject of dress, therefore, with respect to economy, though not considered as of a high class, is deserving of attention, and ought not to be altogether neglected in our work.

5868. *With respect to the tailor*, the principal difficulty is to find out those who can cause their clothes to fit well; and the cutting out of the cloth is one of the great secrets of their trade. Their frequent failure is chiefly owing to the unscientific manner in which their measures are taken, and their not knowing how to make the necessary allowances for the peculiar make of each individual. We would suggest, as an improvement, that they should learn to take measures upon various plaster casts or models of the human figure; and although many may wonder of what use practical geometry can be to a tailor, yet we could easily point out the way in which he would be benefited by some knowledge of that, as well as of drawing and sculpture. We believe the superiority frequently perceived in France among those who are concerned in dress is owing to the general taste for the fine arts, which has descended to a lower grade in the population than in this country.

For those to whom the ordinary expense of clothes is not felt as an object worth much consideration, the most convenient way is that which is most usual, namely, to order them of a respectable tailor, leaving him to state the price, and having one agreed upon. This will generally ensure the best materials and the most fashionable cut. But there are some other modes of proceeding where great economy in dress is aimed at. The cloth may be purchased of a respectable woollen draper, who will generally recommend a tailor to make it up; the difficulty in this case is to get a tailor who can make it fashionable and a good fit, for the tailors who work in this manner are generally persons of inferior skill.

A still cheaper way is to purchase clothes ready made in the shops; but this is one of the worst modes, as there is often some kind of imposition practised, besides the great uncertainty of finding clothes that fit well. Some tailors advertise to make a complete suit of clothes at a very low price, even for three guineas and a half, scarcely the price which others charge for a coat; and although it can scarcely be expected that these can be of the best quality, yet, by a little caution in choosing the cloth, and attending to the tailor's fitting, this is worth attending to where great economy is required in clothes for ordinary wear.

CHAPTER II.

HATS, CAPS, AND OTHER COVERINGS FOR THE HEAD.

5869. Almost infinitely diversified have been the contrivances for protecting the head from the violent effects of the sun, from wet, and from cold; and most nations in the least removed from barbarism have adopted some dress for this purpose. This custom, however, has not been universal. It is said that the ancient Egyptians, in general, went without any covering on their heads. Many of the celebrated warriors of antiquity appear to have followed the same practice. The negroes of Africa, and other savage tribes, go bareheaded; and this was an old Saxon fashion, the remains of which, perhaps, may still be seen in Christ's Hospital boys, who do not suffer from it. It was an ancient maxim to "keep the head cool and the feet warm;" and in dry and temperate climes there probably would be no danger in young people going bareheaded, even if they were much in the open air; but with our artificial habits this could not be generally practised by adults.

The turban is the general covering used by several Asiatic nations, and by the Turks, who came originally from Asia. It is generally composed of a number of folds of cotton or muslin cloth, and is well calculated for defence against the rays of the sun, which are often so violent there as to occasion death. It is the custom, however, in those countries to wear turbans without intermission, in the house as well as out of doors, which makes the head tender, and is unfavourable to strength.

5870. *The woollen bonnet, or cap,* in some form or other, was the most usual covering for the head among the European nations before the invention of hats; and they are still much worn. One of the most simple, and, perhaps, oldest forms, is the common bonnet of the Scotch Highland peasants; but it has a mean look, and its chief recommendation is its cheapness. The Highland military bonnet, sometimes ornamented with feathers, is a degree smarter.

5871. *Various caps of fur* are worn in Holland, Poland, and Germany, and in other countries of Europe. Caps are also made of the skins of young lambs, the wool of which is curled by a peculiar process.

5872. *Caps of leather, sometimes varnished,* are in a great variety of forms, and of late years have been much worn in England by mechanics and young people.

5873. *Travelling caps* are made in a similar way, and are either to keep off the wet entirely, or for sleeping in, where hats would be inconvenient. These are too well known to require enumeration.

5874. *Hats* are not modern, as they were used by some of the ancient Greeks. They are now, and have been for many years, by far the most general article for covering the head in Europe and America, and are probably the best contrivance; they are made of various materials, as felt, straw, chip, willow, whalebone, silk, &c. When the felting of wool and hair for hats was first invented does not appear. The Tartars employ this process of felting in making a kind of covering for their tents; and, although we do not find it mentioned among the arts of the Greeks and Romans, it was known to our Saxon ancestors, though felted hats were not common among them. They seem to have been made in Flanders earlier than in Britain, for in Chaucer's "Canterbury Tales" the merchant wears "on his head a Flaundrish beaver hat."

5875. *A late paper in the "Archæologia" supplies us with the following curious information respecting hats in this country:* The Chronicles of Froissart mention the hats of the time of Edward III. and Richard II., and white hats seem then to have been worn at Ghent as the badge of a political party. But they were by no means common, and were confined to the wealthy till the reign of Henry VIII. Stowe informs us that "the English used to ride, and go in winter and summer in knit caps, cloth hoods, and the better sort in silk-thrummed" hats. In the time of Queen Elizabeth, high crowns came in fashion, and they were often pointed and conical. At that time hats were restricted by act of Parliament to the upper classes of society; the middle and lower being confined, under a penalty, to the use of knit caps. This act, however, was soon repealed, and felt hats came into general use. In 1638, King Charles prohibited the importation of beaver hats, and from this period may be dated the increase in the value of beaver fur.

During the Commonwealth, and subsequently, broad brims were much used, and the Quaker's hat is a diminished remnant of that period. These being often inconvenient, it was the custom occasionally to turn up one or two sides, which led to the three-cocked hat in the time of Queen Anne. About 1750, round hats became very prevalent among the lower orders, and the cocked hat was the distinction of a gentleman. About 1790, cocked hats were laid aside, and ever since round hats have been the universal wear. The various forms of these are too well known to require enumeration; the chief varieties are the high and low crowned. The former are to keep the head cool by the air in the upper part; the low crowned are generally broad brimmed, the better to shade the face in summer.

5876. Plumes of feathers, and the single feather of the peacock, or common fowl, have been worn in the hat in very ancient times. In China, they are a mark of dignity. In modern times feathers have been confined to military men. Particular vegetables have been worn in the hat as badges of party or family; thus, the Welsh wear leeks, and the Irish the shamrock, in certain festivals; and oak leaves have been worn in memory of Charles II. sheltering himself in an oak Cockades have been also used as ornaments. White was the colour of the Stuarts and Bourbons; a black cockade is the family badge of the Elector of Hanover. Large white cockades, called *favours*, are now worn by servants at weddings. It was the fashion to wear large jewels in the hat as ornaments, and hat-bands, with loops and bindings of gold and silver lace, were esteemed as the marks of wealth and dignity; all these have given place to a taste for greater simplicity in dress; and for many years we have had no ornament in the hat beyond a simple narrow black band.

Uncovering the head, or taking off the hat, is a mark of respect almost peculiar to Europeans; in Persia it is considered indecorous.

5877. *Felted hats are made*, in the first place, of a thick close felt of wool mixed with some kind of hair; this is called the foundation; and on the outside of the hat a finer kind of hair is worked in, which, in the best hats, consists of the fur of the beaver, whence the term beaver hats. Some hats appear formerly to have been made entirely of beaver; but this is never done now, on account of the scarcity of the material. There are a great many qualities of hats, from the various kinds of hair made use of either in the foundation or in the covering. Our object is not to go into all the minutiæ of hat-making as a trade, which would extend far beyond our limits, but only to convey a general idea of the mode in which these articles are formed.

5878. *The process of hat-making* begins with felting, which consists in a method of working up wool or hair into a species of cloth, independently of either spinning or weaving, and the mechanism of the process depends in a great measure upon the conformation of all animal hairs and wool, which disposes them to unite by pressure and heat, so as to produce a compact and firm substance. The first process in hat felting is to obtain the most complete separation of the fibres, and to dispose a layer of them in every possible direction with regard to each other. For this purpose, a quantity of the hair or wool is laid upon a platform of wood about four feet wide, and struck repeatedly by means of a bow and string. The workman, holding the bow in his left hand, and placing the bow-string near to the material, plucks it towards him by a pin; the string, in flying back, is made to strike into the wool or other material, and scatters a portion of it to a considerable distance, occasioning it to fall down in a regular layer. By repeated strokes of the bow-string, the whole heap is at last thoroughly loosened, and spread over a part of the platform in an even layer; this is then brought together by the hand into some regular form, according to the kind of hat to be made, and folded up in a wet cloth; it is then laid upon a warm iron plate, and the process of felting is carried on by pressing it by the hands in various directions, and sprinkling with water, by which the mass acquires a certain degree of consistency from the fibres of the hair or wool entangling together. Before the felting is completed, a quantity of fine fur, either of the beaver, or some other animal, as the rabbit, camel, &c., is laid on the outside of the felt, in such a manner as that the ends of the hairs point one way, as on the animal; these are worked in so as to be fixed in the felt, and completely to cover it; and upon the goodness of this fur will, in a great measure, be the quality of the hat. The hats are at first made into a conical form; and, to render them still firmer, they are now boiled with some alkali, and felted again with hot water, and the conical cap is by various processes put upon a block of the desired shape, and worked on till it fits. The edge or rim is now worked out, and cut into the proper shape. The hat is next dried; and its nap is raised or loosened by rubbing it with a brush of wire, and sometimes it is pumiced, to take off the coarser hairs, and afterward smoothed with seal-skin. It is then tied securely upon its block, and dyed black in the usual manner. After being dyed, it is stiffened; this is done by various substances. The most common hats are stiffened with glue, or with gum Senegal; but beer grounds are first applied to the inside as a cheap mucilage, to prevent the glue from coming through to the surface. If the hats are to be water-proof, some substance is used that will not be softened by rain. For this purpose, a varnish is used composed of shell-lac, sanderach, mastic, and other resins dissolved in alcohol or naphtha; some use a solution of India rubber. The finishing of the hats is produced by softening them a little by exposure to steam, and brushing and ironing them till the required gloss is produced. Lining and binding complete the process.

5879. *The materials made use of for felted hats* are chiefly the fur of the beaver, rabbit, and hare, sheep's wool, camel's and goat's hair, cotton, and silk; the first is by far the most esteemed, on account of its silky softness. The furs of the hare, the rabbit, and the beaver, being naturally straight, cannot be felted by themselves till they have acquired a curling property at their points; this is given by the application of nitrate of mercury, an artifice called *secretage*. *Neustria* is an article lately introduced into the manufacture of hats; it is the fur of an animal of that name, a species of water-rat, resembling the otter, and is as fine as the fur of the beaver. Within these fifteen or twenty years, it has been largely imported from South America, to the amount of 800,000 skins annually.

5880. *The colours of felted hats* are black, white, and drab; the first are, of course, dyed. White hats are worn only by ladies, and have a nap of rabbits' fur, selected from the white skins. Drab hats for men are made of stuff of the natural colour, assorted on purpose; they are used for summer wear, absorbing the sun's rays less than black, and being consequently cooler; they are likewise proper for the seaside, the spray of the salt water injuring the colour of black hats.

5881. *Silk hats* are made by fixing a kind of plush with a long nap of silk upon a body of felt, chip, straw plat, or some other material; they have lately come much into use, from their cheapness, and keeping their colour. Several improvements have lately been made in silk hats. When they were first manufactured, they were liable to two objections: the body was hard, consisting of pasteboard, and was apt to hurt the head, from want of elasticity; and the edge of the crown, being much exposed to wear, the silk nap soon got abraded, so as to lay bare the cotton foundation, whence the hat assumed a shabby appearance. Afterward the body was made of felted wool, and the joining of the side with the crown was not made at the edge, but in the crown itself. The plush or velvet employed in covering these hats was, at first, made upon a cotton foundation, which cannot receive the same brilliant black dye as the silk; the best silk hats are now covered with a plush made wholly of silk. It is said that the French make a better silk material for covering hats than we can, and their material is imported by us and put on beaver bodies, which are then called *Paris hats;* this material has a shorter nap, and looks smoother and more glossy than ours. Silk hats are also frequently made upon a very light body, as willow, covered with a plush of floss silk, and sold under the name of *gossamer hats*, which serve very well for summer wear, but which are not calculated for bad weather; some of these are sold so low as five or six shillings, and really, while in good condition, look very well. A fabric has also been woven from threads cut from whalebone, which is extremely elastic and durable; this serves for the body of the hat, and, being stiffened with resinous varnish, the silk is applied on the outside.

5882. *Water-proof hats*, made so by a stiffening applied within of shell-lac, or India rubber, have the inconvenience of preventing the perspiration of the head from escaping, and are, therefore, disagreeably hot, particularly in summer.

5883. *When a beaver or silk hat has been wetted with rain*, on coming into the house it should be wiped dry and brushed, to lay the nap smooth. If put away and suffered to dry without that precaution, the nap will be rough, and brushing will not lay it smooth and restore its gloss.

5884. *Much more attention and care are bestowed upon the hat in England than on the Continent;* here every person of any respectability takes care to appear in public in a good hat. Foreigners are less solicitous about this part of dress.

5885. *Travelling cases are made for hats;* those who wish to preserve this article perfect make use of a travelling cap, and send the hat in its case as part of the luggage.

5886. *Straw hats* are in very general wear for women, and also occasionally for men; they are not a modern invention, the neighbourhood of Dunstable having been celebrated for a century and a half as the principal seat of the manufacture, which employs a great many persons.

5887. *Dunstable hats* are made of whole straw platted in long, narrow strips, or ribands, which are afterward sewed together in the form of a hat or bonnet. The weight and clumsy appearance of these bonnets first suggested the idea of dividing the straw into strips; but it was a considerable time before a method was invented of performing this in a perfect manner.

5888. *Split straw* is an elegant manufacture, brought into use about forty years ago, and has now become very general for women's bonnets. The straw of wheat or of rye is cut at the joints, and the outer skin being removed, it is sorted into small bundles, and is next split by means of a very simple instrument, and delivered to be platted. The plat is sold by the score yards, and about three score and a half will make an ordinary sized bonnet. It is sewed by the bonnet-makers, and then blocked, which is a laborious process; and, after being pressed, wired, and lined, it is ready for sale. There are markets in the plat districts for the sale of straw, plat, and bonnets; the best market for the latter is at St. Alban's. The various forms of bonnets into which the straw plat is worked up, varying continually with fashion, baffles all description, and is a subject well understood.

5889. *Straw is bleached and straw hats cleaned* by putting them into a cask into which a few brimstone matches are placed, lighted. The fumes of the sulphur have the effect of destroying the colour, or whitening the straw. The same effect may be produced by dipping the straw into the chloride of lime dissolved in water, an article which may now be procured at any large chemist's. Of the straw hats, the *Leghorn* are the most highly prized, as the finest in the world; these are made in the neighbourhood of Florence, Pisa, the district of Sienna, and the upper part of the Vale of the Arno, and are exported from Leghorn. The straw is produced from a small kind of wheat cultivated on a poor soil, and bleached like flax; it is remarkable for its strength and whiteness; the plat is extremely regular, and the straw is not split. Attempts have been made to grow this kind of wheat in England, but they have not succeeded.

5890. *White linings to hats or bonnets*, particularly when they are glazed or shining, as some silks, are hurtful to the eyes, in consequence of their reflecting a great deal of light, and are somewhat similar in their effects to snow, which is known to be extremely injurious to the sight. These linings ought to be of dark colours, gray or green, and should not be of glossy materials.

5891. *Various other materials besides straw are used for making light hats.* Several grasses have been tried, but none have been found to equal wheat straw. *Chip*, which is the thin strips of wood made by a plane, is employed; the *willow* is found to answer well, and these strips are woven by a loom into a kind of twill, or diamond tissue, and afterward bleached like straw. A hat made of two folds of this has a considerable resemblance to Leghorn.

CHAPTER III.

SHOES AND BOOTS.

5892. *Historical Remarks.*—The antiquity of these articles of dress is, no doubt, as early as the civilization of mankind. We find that they were worn by the ancient Egyptians; several of their actual shoes, having been preserved to the present day, may be seen in the British Museum; they are formed of matting, the bark of the papyrus, leather, and other materials. Shoes were also used by the Greeks and Romans, though they generally wore sandals, which were merely soles tied on the feet with thongs. It would be endless to mention the variety of shoes that have been in use at different times, and among various nations. The most simple kind of shoes appears to have been merely a piece of leather bound round the foot, and such are still used in remote places in the Highlands of Scotland, where they are called *brogues.* In the reign of Edward IV., shoes were pointed at the toes, and had long beaks of four or five inches, turned up and fastened to the knee by a chain. Afterward we find them quite round at the toes, and ornamented with slashes. In the time of Charles I., the toes were made quite square; and the boots came only half up to the knee, with wide tops turned down. Neither these nor the shoes appear then to have been blacked. Blacking is a very late fashion.

5893. *The shoe consists of* the sole and the upper leather. The part which covers the upper part of the foot is called the *vamp*, and the part which surrounds the heel forms the two quarters; these last are sewed together at the heel, and to the vamp at about the middle of the foot. The sole is composed of the real or lower sole, and the welt, the heel, and the inner or upper sole. Boots and shoes, for comfort and durability, should have upper leathers of fine-grained, well-seasoned *calf leather*, and the soles of stout and well-hammered *neats' leather.* The seams should be wrought with well-waxed thread, in stitches as fine as the nature of the substance will permit.

5894. *Various other kinds of leather* are occasionally used for shoes, though none is equal to that of the calf for wear and keeping out the wet; these are from the skins of goats, horses, dogs, and seals; they are lighter leathers, and sometimes made into dress shoes. Doe-skin leather is extremely elastic, but does not keep out the wet unless prepared by some water-proof process. For the mode of preparing leather, see "Materials of Furniture," Book V., Chap. V.

5895. *There are few parts of our dress in which fashion is so mischievous as in our shoes;* instead of forming them, as they should be, to the shape of the human foot, it would seem as if the latter was to be regulated by the taste of the shoemaker. If we wish to know what is the natural form of the foot, we should observe those who have never been accustomed to wear shoes, and we shall find that all the toes, the little ones included, have their full play, and can be moved about, like fingers, in every direction. The Greeks, who seldom wore shoes, and, consequently, had their toes unfettered, conceived and executed their fine statues according to this perfect form; the little toes are never bent in under the rest, as is almost universally the case in this country, where the feet are often enclosed in tight shoes from infancy; and where shoes do occur in Greek and Roman sculpture, they are always round at the toes. Pointed shoes are not only extremely injurious to the feet, bringing on corns and other inconveniences, but they are really, however the contrary may be supposed, in bad taste, although all-powerful fashion has given them an imaginary elegance.

5896. *The best method of having boots and shoes well fitted* is, after having procured some to fit accurately, to get possession of the lasts on which they were made, and to have in future all new ones made upon them. Some take the trouble of having a plaster cast taken of their foot, and of having a last made from it. The erroneous idea that a very small foot is handsome has crippled many; whereas good taste demands that the foot should have a certain proportion to the rest of the body. The present custom of making shoes to fit each foot, right and left, is much to be commended, and is a great improvement.

5897. *Various leathers besides those of calves* are used in making thin shoes, particularly for dress, where appearance more than strength is the chief quality. Leathers for this purpose are made of the skins of the horse, dog, seal, &c. *Ladies' walking shoes* are also made of some of these thin leathers. The bright, shining varnish now common on dress shoes is called *enamelling.*

5898. *The best boots and shoes are town made,* and to order; but now a very great quantity of both are manufactured in the country, and sent up to London, and it is with these that the sale shops in London are filled. These are much cheaper than what are made in town; but they are likewise inferior in all good qualities, and cannot be depended on; but the convenience of getting them ready made is sometimes an object. Many of these sale shops take orders, but, instead of getting the articles made at home, send into the country for them.

5899 *On the subject of shoes, Dr. Arnott remarks:* "In a graceful human step the heel is always raised before the foot is lifted from the ground, as if the foot were part of a wheel rolling forward; and the weight of the body, supported by the muscles of the calf of the leg, rests for the time on the forepart of the foot and toes. There is at that time a bending of the foot in a certain degree; but where strong wooden shoes are used, or any shoe so stiff that it will not yield and allow this bending of the foot, the heel is not raised at all until the whole boot rises with it, so that the muscles of the calf are scarcely used, and, in consequence, soon dwindle in size, and almost disappear. Many of the English farm servants wear heavy, stiff shoes, and in London may be constantly seen as the drivers of country wagons, with fine, robust body and arms, but with legs which are fleshless and spindles, producing a gait most awkward and unmanly. The brothers of these men, otherwise employed, are not so misshapen; and even they themselves, when they choose to become soldiers, and are trained in military exercises, lose their peculiarity. What a pity that, for the sake of a trifling saving, graceful nature should be so deformed. An example of an opposite kind is seen in Paris, where, as the streets have no side pavements, and the ladies are obliged, consequently, to walk almost constantly on tiptoe, the great action of the muscles of the calf has given a conformation of the leg and foot, to match which the Parisian belles proudly challenge all the world—not aware, probably, that it is a defect of their city to which the boasted peculiarity is mainly due." It may be observed, also, that dancers have always large calves to their legs.

5900. *A machine was invented by Mr. Brunel* for making shoes by uniting the soles to the upper leathers by means of rivets instead of sewing. The leather is likewise cut out by stamps, and the whole of the process being effected by mechanism, very strong shoes are made with great expedition. The army is supplied from a manufactory in which the only workmen employed are the invalid soldiers of Chelsea Hospital.

5901. *The sedentary posture* in which shoemakers generally work being very unhealthy, several inventions have been made for enabling them to follow their trade in a standing position, and are described in the "Transactions of the Society of Arts."

5902. Among the varieties of shoes, we may enumerate

Gentlemen's dress shoes, made of Spanish leather.	Gentlemen's strong walking.	Ladies' double and single soled.
" pumps.	" light walking.	" kid, Spanish, and patent leather.
" dancing.	" shooting.	" satin.
	" Bluchers.	" prunella

5903. *Boots* are not modern. They were worn in the Roman army both by cavalry and infantry. They have undergone as much change of fashion as any other part of dress. The varieties at present in use are,

Top or jockey boots, used for riding.
Wellington boots, which come up nearly to the knee, without tops.
Half, or Hessian, now little used.
Military boots.
Fishing boots, water-proof, or of India rubber.
Hunting boots.
Bluchers, only coming over the ankle.
Oxonian, differ from the last in being tied at the side.
Dress boot shoe, for dinner, but not ball-room dress; useful for saving time in dressing.

5904. *Shoes and boots made completely water-proof* are useful for occasional shooting or fishing, but are unwholesome for common wear, from their confining the insensible perspiration. Leather, when made in the most perfect manner, is impermeable to water under ordinary circumstances, but does not prevent the passage of the perspirable matter. Various preparations have been made to brush over leather and render it water-proof; these are generally composed of mixtures of oil, turpentine, rosin, and wax; in short, any bituminous, resinous, or adhesive matter that will resist acids, alkalies, and water, and will unite with drying oils, provided, when mixed in proper proportions, they do not render the leather hard, or make it crack, or otherwise disagreeable. *A few receipts for this purpose* may be given.

1. Take six gallons of linseed oil, one pound and a half of resin, and four pounds and a half of red litharge, or any other substance known as dryers; boil them together till they acquire sufficient consistance to adhere to the fingers, and draw out into strings, when cooled, upon a piece of glass. It is then to be removed from the fire, and when sufficiently cool it is to be thinned to about the consistence of sweet oil by adding spirits of turpentine to it, which will generally require about six gallons. It is then left to settle for a day or two, after which it is to be carefully poured off from the grounds; about one pound and a half of ivory or lamp black, and some Prussian blue ground in linseed oil, is added and intimately mixed with it. To apply this varnish, lay it on with a brush until it lies upon the surface of the leather with an even gloss; then hang up the article operated upon until the next day, when the application may be repeated, and each successive day as often as is necessary.

2. In six ounces of oil of turpentine dissolve, by gentle heat, three drachms of India rubber, and mix this with eight ounces of linseed oil. Apply it as above.

3. Melt in an earthen vessel, over a slow fire, half a pint of drying oil (boiled linseed oil), one ounce of bees' wax, one ounce of oil of turpentine, and half an ounce of Burgundy pitch, or rosin. If new boots or shoes are saturated with this composition, and left to hang in a warm place for a week or ten days, they will be impervious to wet, and likewise soft and pliable. This composition is used by the fishermen of New-England.

Effectually to prevent the wet from coming through the soles of shoes, some have put a sheet of some impermeable substance between the two soles. Thin sheet copper has been employed, but that is not sufficiently pliable; oil-skin, or a thin sheet of India rubber, will answer. Cork soles put inside boots or shoes are very useful.

5905. *Goloshes* are a kind of wide shoe to put on over the foot of shoes or boots, and they are generally made water-proof. They are now made very perfect of India rubber.

5906. *Clogs* are easier to walk in than pattens, but they throw up more dirt. They consist of a thick sole of wood or leather, worn over the ordinary boots or shoes. Jointed French clogs combine both patten and clog, having the cleanness of the one and the firmness of the other, with flexibility.

CHAPTER IV.

GLOVES.

5907. Gloves are not a modern invention, although they are much more used at present than in former times. Xenophon describes the ancient Persians as wearing gloves, and Varro informs us that they were of long standing among the Romans. But they were often worn only as a protection of the hand in particular cases; in warm climates they were not thought very necessary, and it was only in cold countries that their use became general. Gloves were, in the early ages of Christianity, introduced as a part of monastic costume, and in later periods formed an essential part of the episcopal habit. The glove was employed by princes as a token of investiture; and to deprive a person of his gloves was a mark of divesting him of his office. Throwing down a glove constituted a challenge, which he accepted who took it up, a custom which was continued down to the reign of Queen Elizabeth; and this ceremony was performed, perhaps, for the last time, at the coronation of George IV., when his majesty's champion entered Westminster Hall, completely armed and mounted, and, throwing down his glove, challenged any one to dispute the right of his sovereign to the crown. Gloves were particularly used in hawking; and the custom of presenting them at weddings and funerals is still general. They were formerly considered as a valuable new-year's gift, when they were richly worked and embroidered.

5908. *Gloves are made of various materials*; leather, silk, linen thread, cotton thread, cotton cloths, and worsted. The good qualities of gloves are strength, warmth in winter, coolness in summer, elasticity in fitting well, and to be well sewed in the seams. There is a distinction, also, between those which will bear washing and such as will not; likewise in the manner of sewing.

Of leather gloves there are a great many kinds, according to the quality of the material, or the uses for which they are required. Of these the principal are:

Kid gloves, the most beautiful, from their softness, thinness, and elasticity, fitting the hand almost like a second skin. They are white, and dyed of all colours, but white kid is always worn in full dress. Those of French manufacture are certainly superior to ours in the neatness of the workmanship, and for elasticity they are highly prized. This superiority has occasioned many imitations in this country, and it is said that most of what are sold here for French are, in fact, home-made, from French or Italian skins. We have few goats in England; therefore our kid leather is chiefly imported from Switzerland and Tuscany, whence it comes by way of Leghorn. Most of the lower-priced gloves sold for kid are made of lamb-skin, which is thicker; a vast many are made in Worcestershire.

It used formerly to be the custom in the southwest of Ireland to slaughter many cows while in calf. The skins of these unborn calves were of extraordinary fineness and delicacy, and from such was prepared the leather of which the celebrated *Limeric gloves* were made. This practice, however, is now almost discontinued; and whatever merit the Limeric gloves may still possess is owing to the skill of the manufacturer, and not to the superiority of his raw material, which is generally kid leather. *Beaver gloves* are among the most common of the cheap leather gloves, manufactured chiefly at Hereford; they are dyed of many colours, but they do not wash. *Woodstock* gloves are a superior kind of soft leather, made of lamb-skins, which have the advantage of bearing washing; they are manufactured chiefly at Woodstock, in Oxfordshire, which has been celebrated for them ever since the time of Queen Elizabeth. *Buck-skin* is the strongest kind of leather gloves, and washes well. It may be had white, and of various colours. *Doe-skins* are of a thick, strong, and soft leather; bear washing. *Tan leather* is the name of a very serviceable, strong, and cheap glove for riding, driving, or gardening; its colour is that of bark or tan, and it is either common or York tan. *Sheep-skin* is not much used, except in the army; it is generally white. Leather gloves are likewise sometimes *lined* with fleecy hosiery or fur for winter, and are sometimes *cuffed*.

5909. *Machines have been lately invented for sewing* leather gloves, by which the process is performed more accurately, and which reduces the price. The principal leather glove manufactories in England are at Worcester, Woodstock, Yeovil, Leominster, Ludlow, and London.

5910. *Thread gloves* are either of linen or cotton thread; but it is the former only that are *properly* known in the shops by the name of thread gloves, though it is now a common practice to pass off cotton thread for linen thread. They are a remarkably cool wear in summer, and bear washing perfectly; they are sometimes of unbleached yarn.

5911. *Cotton gloves* are the cheapest of all, and are dyed of various colours; being warm, they are much in use for common wear. Many are imported from Germany of a very low price. *Berlin gloves* are strong, and of white cotton; they were originally imported from the Continent, but are now made in great numbers in Nottingham and Leicester. These, and the other cotton gloves, have almost driven away the common beaver.

5912. *Jean, satteen, and cambric* gloves are cut out of the cotton cloth of these names, and sewed together their use is confined to women. The first are strong, but the cambric gloves are bought merely for their cheapness, having nothing else to recommend them.

5913. *Mittens* are gloves made of various materials, of which the tips of the fingers are wanting, and are used in work that requires the points of the fingers to be uncovered.

5914. *Silk gloves*; these are of various qualities, determined by their weight and the neatness of workmanship. The French white are the best: they are also black, and coloured. A figured silk net glove has lately come much into use among ladies; it is extremely elegant, and cool in summer. Gloves are now also made remarkably cheap of spun silk.

5915. *Worsted gloves* are of many kinds. *Lambs' wool* and *Shetland* are extremely soft and warm. *Dutch knit*, plain and lined, are strong and warm: *German worsted* are the cheapest. Worsted gloves, though not so elegant as others, have a great advantage in their real warmth in cold weather.

The above gloves, of silk, cotton, and worsted, and thread, are now generally woven in the loom; knit gloves, formerly so common, being seldom to be met with. Several other names of gloves may be found in shop lists, and every winter produces something new: gloves of various kinds of *cloth* sewed are now introduced; they are warm, and fit well. Elastic wristbands to gloves are a late improvement.

CHAPTER V.

STOCKINGS.

5916. These, as now made, are comparatively a modern invention. The art of knitting them by hand, with long wire needles, is supposed by some to have come originally from Spain, although it is not ascertained that it was invented in that country. A company of stocking knitters was established in Paris in 1527.

5917. Previously to the time of Henry VII., knitted silk stockings were unknown in England; and Stowe observes, in his Chronicle, "for you shall understand that King Henry VIII. did wear only cloath hose, or hose cut out of ell broad taffata; or that by great chance there came a pair of Spanish silke stockings from Spaine." Thus, although silk stockings had been brought into England prior to the reign of Edward VI., yet we find Stowe commemorating as "a great present" a "payre of long Spanish silke stockings" that Sir Thomas Gresham presented to that king. Thus they were articles of great rarity and value in the time of Queen Elizabeth, for we are informed by Stowe, "in 1560 her silk woman, Mistris Mountague, presented her majestie with a payre of blacke knit silk stockings, for a new-year's gift; the which, after a few days' wearing, pleased her highnesse so well, that shee sent for Mistris Mountague and asked her where shee had them, and if shee could help her to any more; who answered, saying, 'I have made them very carefully on purpose, only for your majestie; and seeing those please you so well, I will presently set more in hand.' 'Do so,' quoth the queen, 'for indeed I like silke stockings so well, because they are pleasant, fine, and delicate, that henceforth I will weare no more cloth stockings.'"

5918. Stockings continued long to be knit by hand in the various countries of Europe, and the machine at present used for weaving them, called the stocking loom, was invented in 1589, by Mr. William Lee, a native of Woodborough, near Nottingham. This machine, to any one who attentively considers its complex operations, and the elegant sleight with which it forms its successive rows of loops or stitches, will appear to be one of the most remarkable strides ever made in mechanical invention. Notwithstanding, Lee met with no encouragement in England: Queen Elizabeth, the patroness of art, was then in her decline; and her successor, James, did not perceive the value of an important manufacture. The encouragement refused by King James was offered by Henry IV. of France, and his sagacious minister, Sully. Under their patronage, Lee settled at Rouen, where he established his manufacture; but being envied by the inhabitants of that place, whose genius he had eclipsed, he was proscribed as a Protestant; and, concealed in Paris, he ended his days in secret grief and disappointment. Some of his workmen made their escape to England, and restored the invention to its native country. It was in Leicestershire, and the neighbouring counties of Nottingham and Derby, that the first manufactories were established, and laid the foundation of the hosiery trade of that district.

5919. The invention of the stocking frame by Lee enabled the English manufacturers to export vast quantities of silk hose to Italy, where they retained their superiority for a long time; for Keysler, in his travels through Europe, so late as 1730, remarks that "at Naples, when a tradesman would highly recommend his silk stockings, he protests they are right English."

5920. In 1758, Jedidiah Strutt, of Becher, near Derby, invented a machine for making ribbed stockings; and the spinning machine of Arkwright was successfully applied to the manufacture of cotton stockings. The factory at Becher is at present the most extensive in the world for stocking making. It employs about 400 silk stocking frames, which produce 200 dozen pairs of hose weekly, and 2500 cotton hose frames, each turning off on an average nine pairs weekly, the whole amounting to little less than 100,000 dozen in the year. The stocking frame so multiplies the article, that stockings which could not be knit in a week are now sold at 9*d.* or 1*s.* the pair.

5921. The yarn for the stocking frame is required to be particularly smooth and equal, and it is therefore spun in a manner different from other yarn, two rows being united to form a thread; on this account, it is called double spun twist.

5922. *Stocking knitting or weaving is a distinct art* from cloth weaving, the manner of combining the thread being essentially different in the two. In the stocking fabric, instead of two threads, the warp and woof, as in cloth, the whole piece consists of one continuous thread, which is formed into a series of loops in successive rows, and the loops of each row are drawn through those of a former row.

Besides stockings, there are woven of the same manufacture a great variety of articles, as under waistcoats, nightcaps, drawers, petticoats, cuffs, gloves, &c., all of which belong to the branch of *hosiery*, a name which comes from the Saxon *hosa*, hose or stockings.

5923. Although the stocking loom has, in a great measure, superseded the use of the knitting needles, the latter are not entirely laid aside; and stockings knitted by hand, though generally less beautiful in appearance, can be more depended upon for durability as well as for accurate fitting. Knitting also furnishes a useful occupation to many persons in situations where it would be difficult to find other employment, and is even at present used as a resource. It is still a common employment among the German ladies.

The manufacture of knitted worsted stockings has existed for several centuries in the Pyrenees. In the valley of Carrol they make annually at present upward of 30,000 dozen pairs, which are exported to Bordeaux, Toulouse, and all parts of France. They are made of Spanish wool, and cost from ten to forty sous a pair. The French government does not permit machines for stocking weaving to be erected there, lest they should injure the employment of the inhabitants.

5924. *All hosiery is to be judged of* by the fineness of the thread and the closeness of the texture, which, in the case of stockings especially, may be partly appreciated by weighing, as it were, the articles in the hand. In ribbed stockings a deception is sometimes practised, against which it is necessary to guard. The spaces between the ribs, which ought to be formed by an inversion of the stitch, contains no stitch at all, but an open range of threads, pervious to weather, and utterly destitute of durability. As the ribs of stockings exposed to sale are necessarily almost in contact, the fault cannot be detected without introducing the hand and opening the tissue, when it will be instantly apparent, and, indeed, will exactly resemble the flaw caused by a dropped stitch in a stocking in wear. In cheap cotton stockings the feet are often cut out and sewed together; but these seams invariably hurt the foot.

5925. *The usual varieties of stockings* to be found at the hosiers' are,

Silk—white, black, coloured, both English and French.
Ditto, with cotton feet.
Spun silk, ditto.
Silk socks—black, gray, gray and white
Cotton—white, black, coloured.
Cotton socks, same colours, and unbleached.
Worsted—white, black, coloured, speckled.
Lambs' wool—white, black, coloured.
Shetland stockings—very fine and soft.
Lambs' wool and yarn mixed.
Angola and *Vignonia*—white, black, coloured.
Woollen socks of the same kinds as stockings.
Fleecy hosiery; an extremely warm fabric, having the outside smooth and the inside covered with a fleecy nap; highly valuable for invalids.
Gauze hose; remarkably thin, worn under silk stockings; they are of cotton and worsted.

5926. Stockings are kept only of a few fixed sizes, which causes some inconvenience in getting well fitted The usual sizes are called

Children's,	Women's full size,	Youths',	Men's out size,
Girls',	Ditto, large size,	Men's,	Gouty hose,
Maids',	Boys',	Slender men's,	Fishermen's hose.
Slender women's,			

Where stocking frames are at hand, stockings can be got made to any size.

CHAPTER VI.

SHIRTS.

5927. Shirts are made of linen of various qualities; of cotton cloth or calico of different kinds, and of checked and striped cloth. Their varieties are too well known to require any description; and they are either made up on purpose, or bought ready made of a great variety of prices. Breasts of finer materials, and false collars, are likewise conveniences universally known.

5928. *Stocks and handkerchiefs for the neck* are parts of dress respecting which we need not give any details, as every one is familiar with them.

CHAPTER VII.

POCKET HANDKERCHIEFS.

5929. These are made of silk, cotton, or linen. India silk is the most durable, and preferred for common wear. They are sometimes imported plain, and printed here, because our colours are brighter and better; still, the India pattern is preserved. *Bandanas* are a kind of silk handkerchiefs manufactured in the East Indies, the patterns of which generally consist of square or circular spots, variously arranged upon a red, blue, or yellow ground. They have been imitated here in cotton, by first dyeing fine calico a brilliant Turkey red, and afterward discharging the colour from those parts which in the pattern are white, by means of liquid chlorine, which is made by adding sulphuric acid to the solution of chloride of lime. An immense number of these are manufactured by Messrs. Monteith and Co., Glasgow, who have a patent for the method of producing the spots, which is done with extraordinary expedition. Twelve or fourteen webs of dyed calico are stretched over each other, and a leaden plate, perforated with holes of the form of the spots, is fixed upon them by a powerful press; the discharging liquor is then admitted into these holes and forced through all the thicknesses of calico. After the chlorine has performed its office, water is passed through to wash it quite away; and then the cloth is bleached, to produce a clear white in the spots. In this process only about en minutes are employed, in which time, by a sufficient number of perforated plates, 224 handkerchiefs are discharged; and 19,200 yards are converted into bandanas in the space of ten hours by the labour of four workmen.

The *Balasore* handkerchiefs, made about Preston and Chorley, and *Pullicats*, made at Glasgow, are other imitations of Indian manufactures. Besides these, cotton handkerchiefs of an infinite variety of English patterns are daily making their appearance.

5930. *White pocket handkerchiefs* are made of lawn or cambric. French cambric is considered the best; some of them have borders, and even fringes. Scotch cambric is not made of flax, but cotton. In this country these are usually worn plain; but in some countries, particularly in the East, they are elegantly embroidered, and are carried much in the hand by ladies.

CHAPTER VIII.

BUTTONS.

5931. Diversified as have been the forms and sizes of this useful article, they yet scarcely exceed the variety of the materials of which buttons have been made. Almost every substance capable of being used in their manufacture has been tried, under the influence of fashion or ingenuity. Among them are, gold, silver, plated copper, pinchbeck, steel, mother-of-pearl, ivory, bone, horn, tortoise-shell, jet, cannel coal, paper, leather, glass, &c.; besides these, there are buttons which consist of a wooden or bone mould covered with silk, mohair cloth, or some similar substance. It will be only possible for us to point out the most remarkable varieties.

5932. It would appear that the most ancient buttons were not circular, as at present, but simply short cylinders sewed on by the middle. The remains of these may be traced in the Hungarian coats, sometimes imitated among us in ornamental dresses.

5933. Buttons may be divided into two general classes: those with shanks, or loops, of metal, and those without. Buttons with shanks are chiefly made of metal. The blanks of the buttons are either cast or stamped out of a sheet of metal; in the former, the shanks are inserted while the metal is in fusion; in the second, they are soldered on. Metal buttons are turned round in a lathe, and the ornaments are executed in a variety of ways, either stamped or cut with various tools, among which are some of great ingenuity.

5934. *Gilt buttons* are made of a mixture of copper with a small portion of zinc, or brass mixed with copper common brass being unfit for gilding. They are cut out of sheets of this metal, and the shanks are affixed by solder. The gilding is performed by means of an amalgam of quicksilver and gold. An amalgam is made by putting leaf or grain gold in quicksilver, dissolving this in nitric acid, and applying the solution to the surface of the buttons, on which a deposition takes place of the metallic portion of the ingredients. The quicksilver being driven off by heat, the gold remains on the buttons, which derive their fine lustre from being afterward burnished. The quantity of gold on gilt buttons is fixed by act of Parliament to be five grains of gold to a gross of buttons, or ten grains of gold to the surface of a circle of twelve inches diameter. The better sort undergo the process twice, and are called *double gilt*.

5935. *Brass buttons* are simply stamped out of sheet brass, and ornaments are struck by a die.

5936. *Plated buttons* are made out of copper plated with silver, and are chiefly used in liveries. The figures or devices upon them are formed by stamping with dies.

5937. *The commonest kind of metal buttons* are those which are stamped in pewter, and chiefly used in the trimming of military jackets; they are of course very soft; but not being intended to bear any stress, but merely to exhibit the number of the regiment, or some such other figure, and to be stitched close to the cloth, they answer well enough.

5938. *White metal buttons* are cast of a composition consisting of brass with a portion of tin, so as to form a kind of bell metal; they afterward are turned in a lathe, then whitened by boiling with grain tin and crude tartar, and polished by a buff, and crocus martis. The shanks are let into the metal when casting.

5939. *Cup buttons* are made of two pieces, either plated or gilt; one is flat, like a common button with a shank; the other is a hemisphere fixed on, which has been punched by a fly press.

5940. *In mother-of-pearl buttons*, where the shanks cannot be soldered, they are inserted in a very ingenious manner. The hole is drilled in the mother-of-pearl, and undercut, so as to be larger at the bottom than at the top; and the shank being driven in by a steady stroke, the elasticity of the mother-of-pearl allows it to go in, but closes afterward, to prevent its coming out.

5941. *Buttons without shanks* are of two kinds. The first are simply disks of turned horn or bone, with four holes drilled through the face for the purpose of sewing them on the dress, and the surface is made concave, to preserve the thread by which they are sewed. The horn buttons are made of cow-hoofs softened in boiling water; and they acquire their form by being afterward pressed into heated moulds. The second kind are circular disks made of horn, bone, or wood, which are afterward covered with cloth or thread of some kind; and, though certainly gilt and other metal buttons have a rich appearance, yet taste has lately demanded that they should give way to those covered with some material.

5942. Formerly button moulds were usually covered with threads of gold, silver, silk, and other costly materials, wound over the mould in a peculiar and ornamental way; this employed a great many hands, and when the present method of covering them with cloth or mohair was introduced, a great outcry was raised, on account of the number of persons which it threw out of employment; and it is not generally known that a penalty of from 40*s*. to £5 per dozen attached to any person who shall cover button moulds with the same cloth as the coat.

5943. Custom alone has made us consider the number of buttons with which our coats are studded as ornamental; but they are on many accounts inconvenient, particularly in brushing the clothes. Formerly, when metal buttons were generally worn, their manufacture, particularly at Birmingham, was immense: of the various kinds in use, it is still very considerable, but extremely variable from the inconstancy of fashion.

CHAPTER IX.

VARIOUS OTHER ARTICLES CONNECTED WITH DRESS.

5944. *Sewing Needles.*—History is silent with respect to the invention of that useful implement, the needle; but it is said that those used at present, made of steel, at first called Spanish needles, were introduced in the reign of Queen Elizabeth. Whitechapel, in London, Redditch, in Gloucestershire, and Hatherage, in Derbyshire, are the places most noted for their manufacture; and, considering the excellence of their workmanship, the small price at which they are sold is truly surprising.

5945. *Needles are made* of steel wire: a coil of such wire, in its soft state, is cut by a large pair of shears into lengths of four or five inches. The bundles of lengths are first to be made quite straight; which is done by putting a ring over each end, laying the bundle on an iron table, and rolling it backward and forward by a flat piece of iron placed upon it. The pieces, cut into the proper lengths for needles, are next to be pointed: this operation is performed by the workman holding two or three dozen at a time upon a dry grinding stone, each wire revolving while in contact with the stone. In consequence of the minute particles of steel which are evolved in a cloud during this operation, and which are necessarily inhaled by the workmen, needle grinding is found to be an employment extremely prejudicial to health. Of late years, several contrivances have been resorted to in order to remedy this evil; but it is said that it is difficult to persuade the sufferers themselves to use them. The eye of the needle is generally perforated by women: the end of the wire is flattened by the blow of a hammer, and the perforation is made by a steel punch, the groove where the eye is placed being made by a particular file. The needles, now perforated, again require straightening by a process similar to what was described at the commencement. They are next to be hardened, as hitherto the steel has been in the soft state. For this purpose, several thousands of them are placed in a cast iron receptacle, in which they are covered with ashes to prevent oxydization, heated to a cherry red, and afterward tempered to a blue colour. Again they require straightening, and then are scoured bright; this is performed by collecting them in regular tiers in a strong cloth, each tier being separated by some fine emery, oil, and soft soap. The parcel, being then tied round with strings, is placed under a loaded box like a common mangle, by the motion of which backward and forward, for two or three days, the needles are rubbed against one another, and the whole come out clean and bright. Lastly, they are picked and sorted, the heads all one way, ready for sale.

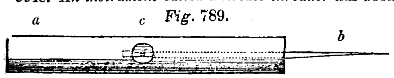
5946. Needles called gold-eyed, silver-eyed, and drilled-eyed, are recommended, as not being so liable to cut the thread. The first are gilt by dipping the heads and eyes in an ethereal solution of gold. The so-called silver-eyed have not a particle of silver, but have their peculiar appearance from a particular kind of polish. The drilled-eyed alone constitute a real improvement, as the sides of the eyes are smoothed after punching, and these are really less liable to cut the thread: the eye is circular, instead of being rectangular as in common needles. The exquisite polish and sharpness of points which the best needles possess is the consequence of a still more careful operation, by polishing them upon a fine stone.

The cheapness of the common sort of needles has often excited surprise, particularly when we consider the excellence of their workmanship; but this is a striking instance of the advantage of a subdivision of labour, every sewing needle passing through the hands of 120 different operatives, during its manufacture, before it is ready for sale; whereas if each needle was begun and finished by the same person, the price of these useful articles would be immensely greater.

5947. The principal varieties of needles are, *crown* or *common; Whitechapel; royal improved; best London; best Chapple; best sorted Chapple; blunts*, used by glovers and tailors; *yarn, looping*, and *knitting needles; Williams's, Davis's, Sheppard's*, and *Boulton's* (these are sold in papers containing 25 each); *worsted darners*, stouter and longer, and the eye larger than the cotton; *packing needles.*

5948. *An instrument called a needle threader* has been lately invented, which is found to be extremely useful to those whose sight is not very good. A small hole is bored longitudinally in a piece of wood or metal of the size of a thick black-lead pencil (*a, fig.* 789), into which the needle, *b*, to be threaded is placed with its eye downward; a hole, *c*, is made in the side of the threader just opposite the place where the eye of the needle will reach to; and this hole is made conical, spreading outward. Although it might be difficult to see the eye of the needle itself out of the threader, yet there can be no difficulty in seeing this conical aperture, and to direct the thread into it; but as soon as the point of the thread is pushed into it, it cannot fail to pass through the eye of the needle, which may then be drawn out threaded. It is obvious that a single threader can only suit one size of needle. This ingenious instrument is sold by Wilks, 186 Regent-street, London; price two shillings.

Fig. 789.



5949. *Pins, such as we now use*, seem to have been unknown in England till about the middle of the fifteenth century. Previous to that time pins were made of ivory, bone, box-wood, and a few of silver, and they were necessarily of large size; and brooches and hooks and eyes were much employed for holding together the parts of dress. In 1543 the manufacture of modern pins had become so considerable as to claim the atten tention of the Legislature; and in 1626 it was introduced into Gloucestershire, which is at present noted for it.

5950. *The process of pin-making*, as it has been usually practised, is the following: The brass wire of which pins are made is purchased by the manufacturer in coils of about 22 inches in diameter; and the first operation, after drawing it to the proper thickness, is to render the wire thoroughly straight, and it is then cut into lengths of five or six inches; and the operation of pointing is similar to what we have described in making needles. It used to be a very unhealthy employment, from inhaling the brass dust; but, by particular contrivances lately introduced, this evil is obviated. A lad twelve years of age will point 16,000 in an hour. When the pointing is finished, the pieces are put into gauges, and the pins cut off to the proper length; and the process is repeated upon the remainder of the pieces of wire. The next process is making and putting on the heads. The head of a pin is made of a piece of smaller wire, twisted about the end and riveted on. The first thing is to convert a piece of small wire into a spiral by wrapping it round another piece of wire the thickness of the pin; and that having been done, the workman divides this spiral with a pair of shears into pieces of two turns each with surprising dexterity, letting them fall into a basin. Fixing these on the pins is performed by women and children. Dipping the pointed end of the pin into the basin containing the prepared heads, they get one of them on, and move it along to the other end where it is to be fixed. Each operator sits before a steel stake having a small cavity, into which one half of the new head will fit; immediately above is a steel die, having a corresponding cavity for the other half of the head; this latter die can be raised by a pedal moved by the foot, and it falls through a very small space, perhaps from one to two inches, the weight being from seven to ten pounds. There is a cavity in the centre of these dies, to admit the body of the pin, and to prevent its being injured by the blow of the die, which is produced by raising it and letting it fall upon the head, for the purpose of tightening it. A single person will head from 10,000 to 15,000 pins in a day.

The pins are now ready to be whitened, or tinned. To remove any grease or dirt which may adhere to their surface, and also to make them a little rough, which facilitates the adherence of the tin with which they are to be covered, they are placed in a boiler with a pickle consisting of water and cream of tartar; after this they are kept for an hour in a boiling, strong solution of tartar, in which grain tin is put, an operation which is repeated once or twice. By an exchange of chemical affinities, the tin is transferred to the surface of the brass pins, which are then removed to a tub of water into which some bran has been put, in order to wash off the acid liquor. The pins, though tinned, are not yet bright; and they are next put into bowls, with hot, dry bran, and well shaken; by this they are thoroughly cleaned and dried, and also polished. The bran is separated by winnowing, and the pins remaining in the bowls are ready for papering. This last process is performed by women and children. The papers are channelled by a sort of crimping iron, and the pins, taken from the bowls by means of a comb which places all the heads in one direction, are pushed through the paper with great expedition, a little iron lever being used for that purpose.

All the processes employed in the art of pin-making, if added together for one pin, would occupy rather more than seven hours and a half of time; yet, by the division of labour, and by making so many at the same time, it is possible to manufacture them with profit for the small price at which they are sold.

The most ingenious machinery for the manufacture of pins is that patented by Mr. Wright, of Wellclose-square, London: by this the whole of the above processes are performed without the assistance of any manual labour; and it has been stated that, if all the establishment were at full work, it could supply the consumption of the whole kingdom, estimated at 16,000,000 pins per day.

5951. *The various sizes of common pins*, as they are found at the haberdashers', are, *Lillskins, short whites, gilt short whites, gilt middlings, gilt corkings*. These are made up in papers. *Pound pins* are sold by weight, in sorted sizes or not. *Lace pins* are very long and slender, for fixing anything on to lace. *Black pins*, and white pins with black heads, are of various sizes. *A new pin* has lately been patented by Taylor and Co., which has the head made out of the same wire as the body of the pin; not put on, as is the case with common pins. *The patent pins*, made by Durnford and Co., are much superior to the common pins, being of stiffer wire, and having the heads flat and better fixed on; their stiffness makes them much more agreeable to use: they are not retailed in less than sixpenny papers.

Thimbles are well-known guards for the tip of the finger in sewing, and to push the needle readily through; they have either a closed end, pitted, or they are without one, and called the *open thimble*, used by needle-men, as tailors and upholsterers. They are made of brass, silver, and steel, or gold and steel.

5952. *Thread.*—It is the usual custom with many haberdashers to describe by the term thread only that which is made of flax, or linen thread; and young shopmen have often no idea that anything else is entitled to this name; whereas it is proper to know that every small line made of fibres of any kind for the purpose of sewing with, or for the rudiments of cloth of any sort, is *a thread*, whatever may be the material; thus, properly, there is not only linen thread, but woollen or worsted thread, silk thread, cotton thread, and even gold and silver thread. In some countries thread is made of a great many other materials, as of the fibres of various plants, and the sinews of animals. Although we have observed that linen thread is the usual distinctive term for that which is made of flax, yet the term *flax thread* would be more appropriate, though this is not in use, since linen is the cloth made from flax, and not the material of thread. When thread is spun for weaving, it is termed *yarn;* when two of these are twisted together for sewing, it is called *sewing thread*, or *twist*, as it is twisted less or more.

5953. *Thread made of Flax, or Linen Thread.*—Much of this was formerly imported from the Netherlands, as Bruges thread, Lisle thread, &c., used for sewing cambric; but these are now superseded by our own manufactures. The greatest quantity of sewing thread is made in Scotland. *White* or *stitching thread* is used for sewing white articles where great strength is required; but, in general, sewing cotton is now so well made that it is very generally employed instead of thread of flax. *Wire thread* is a kind much twisted, used by bonnet-makers. *Patent* or *Shrewsbury thread* is of various colours, and sold in pound papers for sewing strong, coarse articles. *Scotch thread* is of all colours and thicknesses. *Lace thread* is for mending lace.

5954. *The different kinds of cotton thread* are chiefly divided into twist, yarn, and sewing thread. The first is either water twist or mule twist.

Water twist, which we have mentioned in describing the manufacture of cotton, is so named because chiefly made by water mills, and is used for weaving calicoes; it is spun hard with a great deal of twist.

Mule twist is made by steam-engines for weaving muslins and the finest cotton goods, and is somewhat softer than the former.

Stocking yarn, for stocking weaving, is spun softer than twist, and two threads are afterward doubled together, and then slightly twisted round each other.

5955. *Cotton sewing thread*, usually called *sewing cotton*, has of late been made so beautiful by machinery, and its utility and cheapness are so well known, that it has, in a measure, superseded the use of linen thread formerly used. It is used in every house, and in the making of almost every kind of clothing.

5956. *White ball cotton* is of various sizes, distinguished from each other by numbers, or by letters; there is also coloured ball cotton. *Reel cotton* is a superior kind. These are now extensively used for sewing instead of the linen thread employed before the cotton was brought to such perfection; but the latter is not nearly so strong, nor so durable for many purposes, as flax thread. To free cotton thread from its divergent fibres, it is passed rapidly through the flame of coal gas, by which it acquires a more smooth and even appearance. *Mending cotton*, or *darning cotton*, is chiefly used for repairing cotton hose; it is white, black, and coloured, and is composed of two threads but little twisted. *Trafalgar cotton* and *Moravian cotton* are used for working muslins, nets, cambrics, &c., and are quite soft. *Knitting cotton* is for knitting gloves, socks, fringes, &c.; it is twisted hard, but not so hard as sewing cotton. *Marking cotton* is in small balls, and is dyed previously to being twisted, so as to render the colour immoveable. *Lace thread* is also made of cotton, for mending lace or bobbin net. *Gimp thread* is a soft thread used for embroidering on muslin. *Glazed cotton* is another variety for the same purpose.

5957. *Worsted*, or *worsted thread*, is made of wool of various degrees of fineness, and dyed of all colours, chiefly for darning, embroidery, and tapestry.

5958. *Silk Thread, or Sewing Silk.*—In describing the silk manufacture we explained the manner of converting the labours of the silk-worm into thread. What is prepared for sewing is, *fine white, or China silk; common sewing silk, black, and dyed of all colours; tailors' sewing silk; twist, or mohair, for tailors; floss silk*, for darning hose, &c.

5959. *The thread of the Laplanders* is of a very different nature from ours; they know nothing of flax or hemp, nor of any other plant whose stalks might supply the place of these in making thread, but theirs is made of the sinews of the reindeer. They beat these sinews well, after having steeped them long in water, and then they spin them out. The thread is made of any fineness they please, but cannot be longer than the sinews admit. This thread requires much more labour to make than ours; but it is much stronger, and therefore superior on many occasions. In fact, it is very similar to our own catgut, only finer; and with this they sew their clothes, gloves, &c.

Miscellaneous Articles.

5960. *Bindings* are fabrics woven of very narrow widths for sewing on the edges of various cloths, and ties for various purposes. They are made of worsted, cotton, hemp, and flax. *Carpet binding* is of worsted, about two inches and a quarter wide, made very strong; and there is a kind of linen and worsted. Worsted binding is about one inch and a half wide, and is either *common London*, or *double London quality*. *Shoe binding*, narrow, for binding shoes. *Venetian binding* is a finer kind of worsted of various widths, proper for Venetian blinds. Chints binding is for white dimity and printed furniture. *Blue and white bindings* are for mattresses and bed-ticks. *Flannel bindings* of silk and cotton.

5961. *Ferrets* are narrower than bindings; they are of worsted, cotton, or silk.

5962. *Tapes* are the narrowest fabrics of this kind, and are either plain or twilled. *Holland tape* is a white tape of linen, of various widths, described by numbers, as Nos. 13, 14, &c. *Dutch tape* is a finer kind of the same. *Dutch diaper*, or herring-bone tape, is white, of linen, soft and strong. *Pink, red, or lawyers' tape*, of linen. Blue and black tape. There are also cotton tapes of various kinds.

5963. *Webs* are strong fabrics from two to three inches wide, for supporting the seats of sofas, and similar uses. They are made of hemp.

5964. *Fringes* are for furniture or for ladies' dresses. The first are from two inches and a half to four inches deep, and are of three varieties; *plain head, plain head and bullion, gimp head.* Those for dresses are called *fancy fringes*, and are made of worsted or silk, from half an inch in width to two or three inches.

5965. *Laces* are of silk, cotton, or linen; and are made flat, oval, and round. *Stay laces* and *upholsterers' cord* are made of a number of threads from three to twenty, knitted together in a braiding machine.

5966. *Combs* are well-known instruments for disentangling and adjusting hair. They are made of various forms and materials, according to the uses to which they are applied; but we shall confine ourselves at present to those which are employed in dress. Combs are manufactured of all prices, from a few pence to any sum, and sometimes they are set with brilliant stones, pearls, and even diamonds; but those which are most in use are of tortoise-shell and horn, these substances uniting the qualities of strength, elasticity, lightness, and an agreeable colour, suitable to that of the hair. The pieces of tortoise-shell in its natural state are never quite flat; but they are steeped in boiling water for a considerable time to soften them, and are then pressed into the desired forms between iron plates; the teeth are cut with saws, and they are finished with rasps, files, and polishing powders. Horn combs are made of bullocks' horns: after the solid tips are sawn off, the horn is heated over a fire, by which it becomes nearly as soft as leather, and the horns are slit open on one side and pressed flat; they are then plunged into cold water to harden them. The mode of finishing is the same as for tortoise-shell. Lately combs have appeared made of iron japanned.

5967. *The fan* is a very ancient apparatus, having been used by the ladies of Egypt and India, as well as those of modern times, for cooling the face by agitating the air: they were originally made of feathers bound together, like the tail of a peacock when spread out, whence the French name *éventail.* The present usual form is Chinese, and consists of a semicircular piece of paper double, and enclosing slender slips of wood, ivory, or tortoise-shell, susceptible of folding in or expanding at pleasure. Fans, about fifty or sixty years ago, were in high fashion here; at present they are seldom used. Great elegance is displayed in the carved work of some fans, and particularly the Chinese ivory fan-sticks. Those now used are small.

5968. *Braces* are a useful modern invention for suspending the pantaloons or trousers, superseding the necessity of girding the body, as was the case in former times, and which was an injurious practice. They are made of leather, cotton girth, or elastic fabric, by means of India rubber woven in the cloth. The last are the most pleasant wear.

5969. *Veils worn by ladies* are considered prejudicial to the eyes by some oculists; on account of their continually interrupting the view of objects, they render their images upon the retina confused, distracting and weakening that organ. White is the most prejudicial colour.

5970. *Umbrellas.*—The Chinese have used them from time immemorial; and they may be seen sculptured on the ruined buildings of Persepolis, the capital of ancient Persia.

Our umbrellas used formerly to be covered with oiled cotton or linen, or oiled silk; but it is found that these materials, when stretched as the umbrella is opened, keep out the rain sufficiently without varnish. The best sticks are of whalebone; some are of cane, which are very inferior. The lightness of an umbrella is a good quality, and for this purpose the stem or handle is best of bamboo or other cane, which unites strength with lightness. It is very important that the circular wire by which the sticks are connected with the stem should be strong, since it is apt to give way, a circumstance very annoying, as it generally happens when the umbrella is in use. Indeed, we would recommend all travellers to have an umbrella extra strong, and the wire is best of stout copper. *Parasols* are on the same principle as umbrellas, only smaller and made more elegant.

5971. *Artificial Flowers.*—These are beautiful ornaments, and sometimes made with a degree of perfection, as imitations of nature, that is truly surprising. The Italians appear to have been the first people in Europe who excelled in this art, but of late years the French have borne away the palm. Silk was the first substance used; feathers had been employed by the natives of South America with great success, but there is great difficulty in dyeing them. The finest cambric is employed at present in France, taffeta also, and very thin shavings of whalebone. We employ here the same materials, and also stiffened muslin. For the leaves of ordinary flowers there are metal stamps sold in the shops; unusual or fancy flowers are cut out with the scissors; the muslin is generally dyed by the florist. The petals, or leaves, when formed, are fixed on to stems of wire covered with silk, by means of a paste composed of gum Arabic and flour, and made secure by tying. After separate flowers have been thus made, they are formed into groups, and tied together. Much taste is required in arranging the flowers into groups, and fixing them together so as to have a natural play. Artificial flowers are made of various degrees of excellence and price, according to whether they are intended merely to decorate apartments, or to wear in the dresses of ladies. Some are made of an inferior kind, and sold extremely cheap. A great many are made in this country, but it is admitted that we do not equal the French in their best flowers.

Flowers made of thin leaves of coloured wax excel, perhaps, all others in appearance; but they are only fit for ornaments to be kept under glass, and cannot be worn in articles of dress.

5972. *Walking-canes* are made of a great variety of substances. The proper cane is a species of calamus, or reed, which grows in India, and is remarkable for its glossy smoothness; the external thin covering being actual siliceous matter.

Beads.

5973. These well-known ornamental articles have been in general estimation at all times, and in all countries, and are made of a great number of substances.

5974. *Those of glass* are by far the most general, and are of great antiquity, being found not uncommonly in the ruins of ancient Egypt. The principal manufacture of glass beads of all colours and sizes is at Murano, near Venice, and is thus described: Tubes of coloured glass are drawn out into lengths in the glass-houses, in the same way as our thermometer tubes; these are cut into very short lengths, each sufficient for a single bead, by laying them upon the edge of a fixed chisel, and striking them with a blow; the pieces so formed are then put into a vessel containing fine sand and wood ashes, and shaken about until their bores get filled with wood ashes; they are in that state transferred to an iron pan suspended over a fire, and stirred about as before, by which their sharp angles get fused, and each piece assumes the form of a round bead. When this process is perfected, the whole is taken out, and the ashes cleaned from the bores by washing, when they are ready for use. Prodigious quantities are manufactured in this place, at a cheap rate, and are packed up in casks to be sent all over the world.

5975. Beads made of *coral, jet*, and other substances not fusible, are made by turning. Those of *satin spar* are extremely beautiful; and it is proper to know that beads are also made of *fibrous gypsum* that are so like those of satin spar as often to deceive purchasers, but which are extremely soft, and very easily scratched. Beads of *pearl* are well known; good imitations of these are made by filling hollow glass balls with scales of a fresh-water fish ground up with gum. Some of the gems are occasionally employed as beads.

BOOK XIX.

THE TOILET, AND SUBJECTS CONNECTED WITH IT.

5976. *The ordinary business of the toilet is too well known* to require that we should go into all the details respecting it; nor shall we attempt to unveil all the profound mysteries of the cosmetic art, by which almost miraculous effects are daily promised, but seldom performed. Our object is chiefly to point out some circumstances that concern the preservation of health or convenience.

5977. *The term toilet* is originally French (*toilette*), and is derived from *toile*, any thin stuff. It appears to have been first applied to a fine covering of linen, silk, or tapestry spread over a table in a bed-chamber, or dressing-room, to place the dressing things upon, such as dressing-boxes, mirrors, perfumes, combs, pincushions, brushes, razors, &c. Several dressing or toilet tables are described under "Furniture," Book V.

5978. *Dressing-cases* are so infinitely varied, that any description of them, or even enumeration of their varieties, would be an arduous task; and they can only be judged of by inspection and trial, according to the wants of each individual.

5979. *One of the chief objects of attraction in the affairs of the toilet is the care of the skin*, the keeping of which in a condition to perform its important functions has been shown to be essential to health by numerous medical writers. The principal means by which it is effected are the use of the bath, and frequent ablution; but as these will be treated of at length in Book XXVI., on "Health and Sickness," we shall refer to that portion of the work. We propose here to give a few hints respecting some subjects usually included under the head of toilet, such as the hair, the teeth, the ear, the eyes, the fingers and toes, cosmetics and perfumes.

CHAPTER I.

MANAGEMENT OF THE HAIR.

5980. Fine hair has been, in all ages, considered as a beautiful ornament, and the proper management of it is well deserving of attention: as this will be assisted somewhat by a knowledge of its structure and mode of growth, we shall first describe these.

5981. *Each hair* is a hollow tube attached to a root or bulb, which grows in the skin. The shaft of the hair is of a horny substance, but the bulb is furnished with vessels and nerves, as is evident from the pain which is felt in pulling the hair by the roots. When the roots are pulled out, the hair does not grow again. Although the hair is tubular, if it has never been cut it is closed at the points, which are sharp, as may be seen in the large hairs that form the whiskers of animals, and from the hair of which camel's hair pencils are made, which becomes useless if the points are cut off. There is probably a circulation of some fluids in hair, although, from its minute structure, this cannot be ascertained; but it may be inferred from the change that takes place in its colour. It is well known that the hair of the human head is almost always lighter, and sometimes of a different tint, in childhood than it becomes afterward; and as old age advances, it experiences, in most people who do not become bald, the remarkable change into gray. The time at which hair turns gray varies remarkably in different persons; and it is frequently accelerated by great anxiety of mind, of which singular instances have been recorded. The turning gray is very different from falling off; the latter appears the consequence of some decay at the roots, whereas they are only the most permanent hairs that ever become gray; the strongest and darkest coloured are the most liable to the change, and are longer in being shed than those which have preserved their colour. Hair, when gray, appears to be in some degree transparent, and has a remarkable silvery or glistening appearance.

The colour of hair is various, but limited within certain boundaries. It varies from very light flaxen to a deep raven black, and goes through the shades of yellow or golden, to reddish and red, auburn or light brown, and dark brown, and blackish brown.

5982. *The proper management of hair* is very simple. It should be kept as clean as possible, by daily brushing and removal of the scurf that forms upon the skin, and occasional washing with pure water, which will have no injurious effect on the health, providing the hair is not very long, so as to make drying it difficult. To assist in drying it thoroughly, souce the brush in a very little hair powder, and brush it out again; after that a little good perfumed pomatum may be brushed in; too much not only makes the hair greasy, but injures it. There is a natural oil secreted by the hair, which serves to keep it in good order; sometimes this is defective, and the hair becomes dry and harsh; it is then proper to supply the deficiency by a little pomatum or oil. The use of these gives to hair a fine gloss, just in the same way as a mahogany table is made to shine by rubbing it with wax, which fills up all the minute cavities with a smooth substance. A multitude of hair oils are sold by the perfumers under specious names, their compositions being kept secret; and each of them is said to have extraordinary qualities. Most of those which are advertised are expensive, and persons who have tried them agree that their pretended virtues are extravagantly overrated. The oil of *behn* is that which is best adapted for the purpose, having no odour of its own, and not being liable to become rancid.

5983. The oil of behn is used in perfumery as the basis for receiving the fragrant scents of various flowers, which yield little or no essential oil by distillation, but impart their fragrance to expressed oils. This oil is prepared in Egypt, Syria, and Italy, from the nut of *Guilandia moringa*. On standing some time, it separates into two parts; one forms the basis of the fragrant oils, and the other is valuable for the clock-maker, as it does not freeze in the severest cold. It is merely a very pure oil, and, when a little perfume of some kind is added, it forms the oils which are sold under the title of *huiles antiques*, scented with orange flowers, violets, jessamine, roses, bergamot, citron, rosemary, lavender, &c. Those who wish to be economical may substitute purified hogs' lard, in which a few drops of some essence, such as that of bergamot, has been added. Olive oil becomes rancid, and is improper. When hair is allowed to grow very long without cutting, it is observed that it splits at the points, which injures its growth; an inch or two should then be cut off. Curling is best effected in the usual way, by papering. Using hot irons is apt to injure the hair, and the *curling fluids* so confidently advertised have but a very temporary effect, and are injurious.

5984. When hair has become greasy from the too free use of oil or pomatum, it is proper to remove the unctuous matter by good brushing. Occasionally soap is resorted to, or even a weak alkaline lye; but these must be employed with caution, and sparingly; for soap used too often will change the colour of the hair; and as it is a well-known fact that a strong alkaline lye will actually dissolve hair and wool, the incautious use of it, therefore, must be very liable to produce some injurious effects. A little white soap dissolved in spirits of wine is most effectual, and less injurious than soap alone. After this the hair must be well washed with water.

5985. The plentiful growth and agreeable appearance of hair is usually promoted by general health and simple management; and more dependance may be placed on them than on any arts which the perfumer may pretend to.

5986. *The loss of hair which occasions baldness* is a usual effect of old age; but it takes place not unfrequently at earlier periods of life. Premature loss of hair is indicative of some derangement of the bodily system, by which the ordinary functions of the skin are in a defective state. The causes of this may be various, and are not easily investigated. It is a very common result of acute fevers, and even of strong mental excitement. Though the hair has begun to come off, this effect will sometimes cease with the return of perfect health; and whatever can restore the proper action of the skin will contribute most effectually to preserve the hair. But when baldness has actually taken place for some time, it may well be doubted whether any application can reproduce hair upon the part from which it has disappeared, particularly after the person has advanced to a certain time of life. This defect is almost peculiar to men; women at an advanced age, though their hair becomes white, are seldom affected with this disease. When the hair is observed beginning to come off, the defect is frequently owing to a dryness of the skin and some want of nourishment at the roots; in that case a little good pomatum or purified hogs' lard may check the evil, and prevent its extending.

5987. In the daily papers are seen numerous advertisements of preparations for restoring the hair which has fallen off; and we are confidently assured that, through their virtues, thousands of persons who had been bald are now adorned with luxuriant tresses. It is really amusing to observe how far impudence can go, and credulity can lead to being duped; and one would imagine that the extravagant style and gross ignorance displayed in these puffs would be sufficient to expose them. The best of these nostrums, that is, those which contain nothing deleterious, are little more than some of the ordinary fats or oils we have mentioned, coloured and perfumed, and which any persons may prepare for themselves at one twentieth of what they cost in the shops, to say nothing of the latter being totally useless as to the purpose for which they are recommended.

5988. Although there is a very general idea that the fat of the bear, or *bear's grease*, promotes the growth of hair more than any other material, in consequence of the extravagant puffs by which its sale is announced, yet it is, in fact, no more efficacious than common pomatum, which it much resembles. Indeed, it is more than probable that the greatest part of that which is sold for bear's grease never came from that animal. Rea' bear's grease has a very disagreeable smell; and this is imitated, it is said, by usin the fat of an old goat, or rancid hog's lard. The least evil is, that the weak and cre ulous will throw away their money; but there is the greater danger that they may b seriously injured by compounds made up by persons ignorant of the nature of the ingredients they put together, and totally unfit to be trusted when health is so much concerned. Among the substances said to make hair grow, we find also enumerated bees burned and pounded in oil of roses, decoction of box-wood, juice of cresses, onions, nettles, and sage; oil of chamomile and of Palma Christi, fox and goose grease, burned butter, honey water, ashes of rats, moles, hedgehogs, &c.! the efficacy of which we may be permitted to consider as extremely problematical.

Among the advertisements we have alluded to are sometimes the most absurd names, as *oil of talc*, talc being a substance from which no oil whatever can be extracted. *Blistering the bald part* has been lately announced as a sure method of making hair grow upon it; but until this has been confirmed by competent medical practitioners, we would not advise any one to make the experiment.

5989. *For dyeing the hair* various nostrums are sold. In most of these the composition is kept secret, and therefore they are not safe to use; but the basis of the black dyes formerly employed consisted of *nitrate of silver*, or lunar caustic, which, although it does turn the hair black, is at the same time injurious to it if used frequently, and, besides which, stains also the skin and the fingers. A dye is now used which is said to be free from these defects: it is composed of litharge, or vitrified oxyde of lead, with lime well powdered in a mortar, and mixed in water in the proportion of 85 parts by weight of the former to 15 parts of the latter. The manner of using it is the following: After the hair has been washed with warm water and soap to free it from grease, and afterward dried, it is to be well covered over with this mixture, of the consistence of cream, beginning with the roots. Four folds of soft brown paper are then to be placed over the whole, and secured by an oil-skin cap. The hair must remain in this condition from three to six or eight hours, according to the depth of shade required, and the cap may then be removed. Some of the dye will fall out, and the rest must be combed and brushed out when the hair is dry. Washing the hair with water should be avoided for three or four days, as that renders it brittle and irritates the skin; otherwise this dye does not injure the hair. But the safest mode is to purchase the dye of some chemist on whom dependance can be placed, as Mr. Garden, of Oxford-street, London. It is to be observed that, as the hair grows, the parts next the roots will be undyed; but, from the usual mode of wearing the hair, this is not seen immediately; but the dyeing, on this account, requires renewal every two or three months.

Powdered crude antimony (sulphuret of antimony) is employed by women in the East to stain their eyebrows black. The Persians are said to be very skilful in dyeing their hair a glossy black, and frequently practise it. A black-lead pencil is also often employed to colour the eyebrows; but this comes off by washing.

5990. *Depilatories are substances for removing superfluous hair;* but they are mostly unsafe to use, the general basis of them being either yellow orpiment, which is a preparation of arsenic, or caustic alkalies, and sulphate of barytes; all of which, in removing the hairs, injure the skin, and their absorption may be dangerous. The *Oriental rusma* is one of the most celebrated of these: it is composed of two ounces of quicklime, half an ounce of orpiment, and strong alkaline lye, of course extremely caustic. It is sometimes tempered by the addition of a little starch or soft soap, so as to form a pomade. By its use the hair is removed in a few minutes; but we cannot recommend it. Plucking out the hair by the roots, though more painful, is less dangerous.

5991. *False hair* is well known, and is useful. It is made up of every shade and quality. Hair which does not curl or buckle naturally is brought to this state by art, in the following manner: After having picked and sorted the hair, and disposed it in parcels, according to its lengths, they roll these up and tie them tight down upon little cylindrical instruments called pipes, of wood or earthen-ware; in this state they are put into a pot with water, over a fire, to boil for two hours. When taken out, they are dried and enclosed in brown paper, and baked in an oven.

5992. *Hair powder*, at one time universally worn, is now scarcely used, except for occasionally drying or cleaning the hair, and similar purposes. It is merely wheat starch powdered very fine. It was formerly made of various colours, and perfumed.

CHAPTER II.

THE TEETH.

5993. Without going into the description of the anatomical structure of the teeth, we may observe that they are composed of an internal part of *bone*, and an external coating of a harder substance, called *enamel*, which consists of phosphate and a little carbonate of lime, in a very dense form, without any gelatin. Each tooth has a root or fang, an artery, a vein, and a nerve; and it is the exposure of the latter to the air that frequently causes the toothache, when this is owing to what is termed a hollow tooth; in other words, when part of the substance of the tooth has been destroyed by caries.

Teeth are of three kinds: front teeth, or incisors, for cutting the food; eye teeth, for tearing; and molar, or double teeth, for masticating or grinding. When the teeth decay and are lost, the digestion suffers from the deficient mastication of our food; hence health, as well as comfort, depends much upon their preservation. When any are lost, it is advisable to have them replaced by artificial ones, which, if done well, will serve the purpose of mastication. If the caries is discovered at any time by observing a small hole in one of the teeth, it may be filled up or plugged, which generally prevents the decay from spreading farther. The good colour of the teeth gives an idea, not only of good health, but of a proper attention to cleanliness and good habits. They should be washed every morning and evening; but merely washing the mouth with water is not sufficient; it is necessary to use a brush, with or without tooth-powder.

If the teeth are neglected, they are apt to be covered partially by an incrustation of a hard, stony substance, called *tartar*, which tends to destroy them by injuring the gums. The formation of this substance is prevented by frequent cleaning and brushing: if it has taken place, it should be removed by the dentist, and not by acids, as some improperly recommend. Too frequent brushing, also, with rough tooth-powder will wear off the enamel, and produce the evil it was intended to avoid. Some receipts for proper tooth-powders will be given. Many of those advertised for sale are pernicious, as well as the tinctures.

5994. *Safe tooth-powders* may be had of respectable dentists; but the following is recommended by Mr. Brande: "Finely powdered charcoal forms an excellent powder; it cleans the mouth mechanically and chemically; but as alone it is dusty, and not easily miscible with water, it may, for this purpose, be mixed with an equal weight of prepared chalk; and, if requisite, scented with a drop or two of oil of cloves." Another tooth-powder consists of prepared chalk, with a little Peruvian bark, bole ammoniac, cream of tartar, and orris root; or charcoal made of burned bread pounded and sifted, a little salt, and orris root. It is to be observed that the cream of tartar is hurtful, owing to the excess of its acid.

5995. *The Breath.*—When this is of an unpleasant kind, the cause generally lies in the lungs or the teeth. The treatment of the former does not come within our limits; it is only for us to say that health must be sought for; no specific remedy will be of any avail as a permanent cure. When it is owing to the teeth, what we have already said may be sufficient. For other details respecting the teeth, the reader is referred to Book XXVI., on "Health and Sickness."

CHAPTER III.

THE EAR.

5996. This is a delicate organ, and must be treated with great caution. Almost the only thing that is safe is to wash it daily, externally and internally, with simple water as far as a towel with the finger can reach. The practice of using ear-pickers is scarcely safe, and has been known to produce deafness by injuring the ear. In case of incipient deafness of some duration, an experienced surgeon should be consulted: some of those persons who assume the title of *aurists* are not to be depended upon.

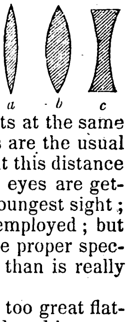
CHAPTER IV.

THE EYES.

5997. Every one must be aware of the value of preserving these unimpaired as long as possible, and also of knowing what remedy to apply when they become defective. For weak sight at an early age, being usually dependant on the state of health, a skilful physician is the best adviser; but there are defects of vision which can, fortunately, be corrected by spectacles, and it is the choice of these we wish to explain.

5998. As old age draws on, every one finds a difficulty in reading a book held at the usual distance, and feels the necessity of holding it farther off to see distinctly; this evil increases until distinct vision cannot be had but at a much greater distance, and, at last, this distance becomes so great that the apparent size of the letters is too much diminished to discern them. This defect, the natural consequence of old age, is owing to the convexity of the eye having diminished; and it is to be remedied by using spectacles, the glasses of which are what are termed by opticians *double convex*, of which *a* and *b*, *fig.* 790, are sections, showing that they are ground thicker in the middle than at the edges. When the defect is first perceived, glasses with a slight degree of convexity will do, as *a*, which opticians call the *first sight;* but after a few years, the eyes becoming still flatter, glasses more convex, as *b*, are necessary to enable one to see to read distinctly at the usual distance; and on every increase of a few years it will be required to have them more and more convex, or what are termed older sight. The more convex the glasses, the more they magnify, or the larger they make objects at the same distance appear. In general, when the eye is perfect, six or eight inches are the usual distance at which we hold small objects to view them, such as a book; but this distance is not exactly the same for all persons. To choose spectacles when the eyes are getting old, begin by trying glasses that magnify least, or what is called the youngest sight; if these enable one to read at the usual distance, they are the kind to be employed; but if vision is still indistinct, try a higher magnifying power, and so on until the proper spectacles are found; but be careful not to use a higher magnifying power than is really necessary, otherwise the evil of age will be brought on prematurely.

Fig. 790.



5999. *Persons are said to be long-sighted* when the defect is owing to the too great flatness of the eye, which is occasionally, but rarely, natural, as well as produced by age; the defect relates only to near objects, for they generally see objects at a distance as well as ever. It is proper to begin to use spectacles as soon as the eyes are discovered to be defective through age, and some injure their sight by avoiding to use glasses longer than is prudent. The first sight, or lowest magnifiers, are often called *preservers*.

Short-sighted persons are those whose eyes are naturally too convex, a defect which has existed from their childhood. The consequence of this defect, is, that objects at a distance cannot be perceived distinctly, although they see near objects perfectly well, and, indeed, better than other persons, for eyes of this kind are, in fact, of themselves magnifiers; but so deficient is their sight with respect to distant objects, that sometimes they can scarcely discern any thing clearly across a street, and some have been known never to have observed the horizon until they saw it through glasses. As we have observed that all eyes get naturally flatter by age, time will correct this defect, wholly or in part, by rendering the eyes less convex; but, in the mean time, to do the same by means of spectacles, their lenses must be ground very differently from magnifiers: they must be *concave glasses*, ground thinner in the middle than at the edges, as at *c*, and such glasses diminish objects instead of magnifying them. Short-sighted persons require these glasses most out of doors, for, without them, they can scarcely recognise their friends. Ordinary spectacles with two glasses are by much the most convenient and best for the eyes, whether convex or concave; but single lenses of either kind are occasionally useful, as they may be worn fastened to a riband, and may often be used more expeditiously than spectacles that require to be kept in a case; but the habit of using them in reading is said to injure the sight. Common cheap spectacles sometimes appear to answer as well as those which cost three or four times the money but very cheap glasses are not to be depended upon: they are sometimes ground irregularly and imperfectly, and then they injure the eyes. It is better, therefore, to have spectacles from a respectable optician, who has a character to maintain. Spectacles having lenses called *pebbles*, made of rock crystal, are not liable to be scratched like glass; but they are not in any degree better than those of glass for vision; and, if care be taken of the latter, they do just as well.

CHAPTER V.

HANDS AND FEET.

6000. So much care is now bestowed upon the hands by some persons, that it would seem as if it was not supposed they were made to be used; nevertheless, it is essential in good society to have them in the proper condition. When any sort of work is to be done that will injure them, it is best to wear gloves. Farther than that, and washing them frequently with soap and water, and a soft brush, much attention is, perhaps, not requisite. When they are chapped in winter, they may be covered with one of the pastes mentioned among the receipts for pomades, and cold cream is often an agreeable remedy. The nails require particular care, otherwise they are apt to become coarse and split. The skin at the root is disposed to grow too far down, and when it does it should be removed. Nails, when in their best state, have so much transparency that the colour of the flesh beneath is seen through, and they have a fine polish. Nothing is more unseemly than not to clean out below the nails regularly every morning, and they should be kept properly pared, neither too long nor too short.

The feet require equal care. They should be frequently washed, and, above all things, tight shoes should be avoided, if it be wished to keep away corns. When these or chilblains occur, the directions should be followed that are given in Book XXVI. The toe nails are best cut with scissors or nail-nippers: in paring them with a penknife elderly persons are apt to wound the flesh, which to them is sometimes dangerous, the circulation in the extremities being so feeble that mortification is occasionally the consequence of a slight wound.

CHAPTER VI.

SHAVING.

6001. Various have been, and still are, the customs respecting *the beard* among different nations. Ancient writers have made honourable mention of the fine beards of antiquity. Homer describes the white and flowing beards of Nestor and of Priam, and Strabo relates that the gymnosophists of India were solicitous to make the length of their beards an object of popular veneration. The Romans did not begin to shave till the year of Rome 454, when a number of barbers were brought into Italy. The custom, however, never became universal, and we find some of the Roman emperors with, and others without, this ornament. The ancient Germans and Franks generally wore only mustaches; but the Normans had a great aversion to any part of the beard, and William the Conqueror found some difficulty in compelling the English to follow their example in removing the whole of the beard. In the fourteenth century beards were again in fashion; but towards the close of the sixteenth they were reduced to mustaches, and, by degrees, afterward shaving the whole face became general. The Russians were long extremely tenacious of their beards, and among the Turks it is considered infamous to have it cut off. The Jews wear a beard on the chin, but not on the upper lip; and they, as well as the Turks, have been in the habit of anointing and perfuming it. Notwithstanding, however, the great fondness for, and respect very generally paid to, the beard, there are certainly numerous inconveniences in this male appendage, and modern cleanliness had banished it from the British Islands, though it seems inclined to reappear among us.

6002. Every one knows how desirable it is to shave with comfort, and, to do this, proper apparatus is essential. Previously to the operation of using the razor, the face should be washed with *tepid*, not warm, water, and a good lather laid on with a proper brush; some prefer cold water. The soap is to be rubbed to a lather in a soap-dish, or shaving-box; others prefer first wetting the beard, and rubbing the cake of soap on the face, and making the lather with the brush on the skin, which is the most effectual way when the beard is very strong. Instead of soap some use *shaving paste*, which may be made by melting together one drachm each of almond oil, white wax, and spermaceti; beat them up with rose water and a square of Windsor soap. *A liquid for shaving* may be made by dissolving eight ounces of Castile soap in a pint of spirits of wine.

After the operation the face ought to be washed with *cold* water, and the razor wiped dry either with a cloth or piece of wash leather: it is usually dipped into hot water prior to using it; a practice, however, not always necessary.

6003. *A good pair or set of razors* is essential, and the safest method is to procure them of a respectable cutler; not but that many common and cheap razors turn out very good, for the value of the material is little, and the steel made in the way of ordinary manufacture sometimes happens to be of very good quality, but this is an uncertainty.

6004. *A keen edge may be kept on the razor for some time by the use of the strop*, and some recommend stropping it every time after it has been use, and before it is put by. The reddish material with which one side of razor strops are covered is a preparation called *crocus martis*, an oxyde of iron, made into a paste with hogs' lard or spermaceti ointment; the other side of the strop is covered with fine black-lead and lard. There is some art in stropping a razor well; if done badly, the edge is apt to be rounded. It is convenient to keep some of the paste in a box, and to put occasionally a little upon the strop by spreading it with a knife before the fire. A cylindrical strop has lately come into use, and appears to be an improvement, as there are no edges. There is also a proper mode of using the razor, which is not intended to cut as a direct cutting instrument by a movement similar to scraping, but by the same movement as a mower uses in cutting hay with the scythe.

6005. *Setting a razor*, or giving it a keen edge, after having been dulled by use, and when the strop is found insufficient, is generally performed on a stone called a *hone;* but the exquisite edge given by cutlers can rarely be produced by those persons who are not in the habit of setting, from a want of skill and sleight of hand, which long and constant practice only can give in perfection. Various contrivances have been made to assist the inexperienced operator.

6006. *A hone has been invented by Mr. Fayrer, of Pentonville*, which is of a novel kind. It consists of a plate of brass about an inch wide, on which is put oil and some fine powder of oil-stone, or of water of Ayrstone. The hone is swung on pivots, in consequence of which the surface always applies itself evenly along the edge of the razor, in whatever direction the pressure of the hand is made that holds the tool.

6007. *The following contrivance for sharpening razors* is given in the Journal of the Royal Institution by Mr Knight, president of the Horticultural Society: "The instrument consists of a cylindrical bar of cast steel, three inches long without its handle, and about one third of an inch in diameter. It is rendered as smooth as it can readily be made with sand, or, more properly, glass paper, applied longitudinally, and it is then made perfectly hard. Before it is used, it must be well cleaned, but not brightly polished, and its surface must be smeared over with a mixture of oil and the charcoal of wheat straw, which necessarily contains much siliceous earth in a very finely-reduced state. In setting a razor (observes Mr. K.), it is my practice to bring its edge (which must not have been previously rounded by the operation of a strop) into contact with the surface of the bar at a greater or less, but always at a very acute, angle, by raising the back of the razor more or less, proportionate to the strength which I wish to give to the edge; and I move the razor in a succession of small circles from heel to point, and back again, without any more pressure than the weight of the blade gives, till my object is attained. If the razor has been properly ground and prepared, a very fine edge will be given in a few seconds; and it may be renewed again, during a very long period, wholly by the same means. I have had the same razor, by way of experiment, in constant use during more than two years and a half, and no visible portion of its metal has within that period been worn away, though the edge has remained as fine as I conceive possible, and I have never at any one time spent a quarter of a minute in setting it. The excessive smoothness of the edge of razors thus set led me to fear that it would be indolent, comparatively with the serrated edge given by the strop; but this has not in any degree occurred, and therefore I conceive it to be of a kind admirably adapted for surgical purposes, particularly as any degree of strength may be given with great precision. Before using a razor after it has been set, I simply clean it on the palm of my hand, and warm it by dipping it into salt water; but I think the instrument recommended operates best when the temperature of the blade has been previously raised by the aid of warm water." The handles of the best razors are made of ivory. The greatest number of common razors have their handles of horn, dyed black and pressed; others are mottled, to imitate tortoise-shell.

CHAPTER VII.

SOAPS FOR THE SKIN.

6008. For the general theory of the action of soap, and of the manufacture of the common kinds, we refer the reader to Book XXII., on "The Laundry." But it will be necessary here, in describing those kinds that are used for cleansing the skin, to point out the way in which that effect is produced; and for this purpose we cannot avoid repeating some facts that we have already mentioned. The union of alkali and oil forms soap; and though oil is not soluble in, or miscible with, water, soap is perfectly so. The skin is covered with an infinity of very minute pores, through which exudes constantly a perspirable matter, partly of an oily nature, and which keeps it in a soft state. To this matter the dusty particles with which we are constantly coming in contact adhere, and fill up the pores of the skin, or cover it partly with a coat of dirt. To remove this oily or greasy matter, we require only to add to it alkali, which would form a soap; and as we stated soap to be soluble, this newly-formed soap on the skin might be easily removed with the dirt adhering to it by washing with water alone. But alkali by itself, such as pearlash or soda, would, by its causticity, injure the texture of the skin, and, if employed frequently, would produce disease, such as red excoriations blotches, and eruptions. But in common soap the greater part of the alkali is already combined with oil, and therefore the only portion of it that can act upon the skin in the way we have described is that which the soap may possess more than is sufficient to neutralize the oil in it. From this it is evident that the more alkali soap has the stronger it will be, or the more detergent, but then, also, it will be the most apt to injure the skin.

It is of some importance, therefore, with a view to keep the hands in good order, that the proper sort of soap should be used. The hands of some persons are apt to be too dry, and require softening by the use of ointments or pastes, while others have their hands too moist. For these it is requisite to use soaps of different qualities. For the toilet soaps, some perfume is generally added; they are also frequently coloured in various ways.

6009. *The most beautiful soap* is the fine white soap prepared from olive oil and soda, extracted from the best barilla, which is manufactured largely in the countries where the olive grows, particularly the south of France, for which Marseilles is the most celebrated; also some parts of Italy and Tripoli. This soap is sometimes artificially marbled, or streaked with red and blue veins; and the marbled soap is harder than the white, requiring to be drier to take the marbling.

6010. *Windsor soap* is the kind most generally used by men for the toilet. The best is made of one part olive oil to every nine parts tallow, and the more common of tallow only; these are united to barilla, and scented by oil of caraway, oil of anise, or some other perfume. It is made white and brown.

Curd soap consists, according to Dr. Ure's analysis, of 52 parts fat, 6 soda, and 42 water, in 100 parts; nine tenths of the fat is tallow.

6011. An almost infinite variety of soaps have been made by perfumers, every one recommending his own; but the basis of them all is good soap of the ordinary kinds, either soft or hard, which they remelt and mix with various perfumes. The soaps are reduced to thin shavings, and these are put into a copper pan in a water-bath. If the soaps are new, they will melt on the application of heat; but if they are old, a little water is added. When the fusion is complete, some perfume, and, if required, some colour, is added, and the soap is poured into moulds. Formerly many foreign soaps were imported, and many counterfeit soaps were sold under their names, as Joppa soap, Smyrna, Jerusalem, Genoa, Venice, Marseilles, Gallipoli soaps. At present these have mostly given way to our English soaps. The following is the composition of some of the perfumed soaps:

Cinnamon Soap.—30 pounds of good tallow soap, 20 ditto of palm oil soap; perfumed with 7 ounces of essence of cinnamon, 1¼ ditto of sassafras, 1¼ ditto bergamot; colour, 1 pound yellow ochre.

Orange-flower Soap.—30 pounds good tallow soap, 20 ditto palm oil soap; perfumed with 7½ ounces essence of Portugal, 7½ ditto amber; colour, 9½ ounces of some yellow green pigment and red-lead.

Musk Soap.—30 pounds good tallow soap, 20 ditto palm oil soap; perfumed with 4½ ounces powder of cloves, pale roses, gilliflower, essence of bergamot, and essence of musk, each 3½ ounces; colour, Spanish brown.

Bitter Almond Soap.—50 pounds of best white soap, 10 ounces essence of bitter almonds.

Soap à la Rose.—30 pounds olive oil soap, 20 of good tallow soap; perfumed with 3 ounces essence of roses, 1 ditto cloves, 1 ditto cinnamon, 2½ ditto bergamot.

Soap au Bouquet.—30 pounds good tallow soap; perfumed with 4 ounces bergamot, 1 ounce each of oil of cloves, sassafras, thyme, and neroli; colour, brown ochre.

Naples soap is a strong soft soap, scented; it comes to us in pots.

The best Castile soap comes from Spain, and sometimes it is imported from Marseilles. It is used medicinally; but a great deal is made in this country by pouring the best white soap into moulds, and giving the marbled appearance by some solution of sulphate of iron in water.

Transparent soap is considered by some as an elegant variety: it is made by dissolving Windsor soap in spirits of wine, cutting the soap in slices, putting them into a large vial with a sufficient quantity of the spirit, and letting it remain before the fire till the whole is dissolved, using no more spirit than is just necessary. When this solution is poured into a mould, it becomes solid in cooling, and retains its transparency. There is no particular advantage in using it; on the contrary, it is seldom so good as ordinary soap, and is apt to spoil.

Palm soap is made with palm oil and soda: it has a smell peculiar to itself, which is not liked by every one.

Soap balls, or *wash balls*, for washing the hands, are made of various colours, by simply cutting white soap into small pieces, rolling them in vermilion, blue, or other colour, and squeezing them together into balls. They are scented with various perfumes; but they are at present little used.

Soft toilet soaps are generally made of hogs' lard and alkali, and are in great request for shaving.

Pearl soft soap is an elegant soap of this kind; it is also called *almond cream.*

6012. *Milk of roses* is a saponaceous liquid, formed by mixing the liquid obtained by exposing potash to the air with rose water, and then adding to this oil of almonds, till the mixture becomes milky without being greasy. It may be doubted whether any perfume or other addition to soap can improve it in its most important use. If there is too much alkali in the soap, that is, if it be too strong, it will make the skin rough. Perhaps nothing exceeds good Windsor soap.

Some prefer oatmeal to soap for washing the hands; it is certainly less likely to injure the skin.

6013. *Freckles and Pimples.*—We abstain from giving any of the very numerous receipts for removing these, although they are common in books that treat of cosmetics, because we consider many of the applications useless and absurd, and some highly dangerous. Freckles are the result when certain persons have been much exposed to the sun; there is generally a constitutional liability to this defect, for which the only safe and sure remedy is to guard the face by a veil or parasol: with respect to pimples, we consider that no applications should be made without medical advice, since incalculable mischief may be done by employing the nostrums that are usually recommended, some of which are dangerous, being repellents which drive inwardly what nature is endeavouring to throw out. We refer the reader to the medical part of this work, in Book XXVI., for advice on this subject.

CHAPTER VIII.

COSMETICS.

6014. *General Observations.*—The desire of being agreeable has, no doubt, led to the invention of cosmetics. Under this term are usually comprehended all the expedients invented to soften the skin, to maintain its transparency, lustre, and freshness, to give colour to the complexion, to prevent or efface wrinkles, to whiten and clean the teeth, to stain the hair and eyebrows, and, in short, to improve the appearance of the face and hands.

6015. The term is derived from the Greek *κοσμειν*, to adorn: the Greek ladies, we are told, studied much the use of cosmetics, as the women of the East do at the present day; hence, we see frequently advertised various nostrums under the title of *Circassian bloom*, &c. When we consider the anatomical structure of the skin, and how easily it absorbs substances applied to it, it is evident how careful we should be not to use any deleterious materials for the face and hands, and that we should know accurately the nature and composition of all substances recommended by perfumers. The intimate connexion between the functions of the skin and those of the stomach were not so well understood formerly as they are in the present day; and hence many practices were resorted to in the use of cosmetics that are now known to be very improper. Nevertheless, all cosmetics are not to be condemned equally; some are, perhaps, harmless, and others are occasionally useful. We shall illustrate this by a few general remarks. Of paints for the face, which are occasionally employed, some, as we shall show, are highly dangerous; and those which are not so have an injurious effect, if used constantly, in stopping up or clogging the pores of the skin. Those cosmetics which owe their efficacy to vinegar and alum, or any other acids and astringents, are often for a time efficacious, giving a firmness and lustre to the skin; but this effect is merely temporary, for they in time alter its texture, dry it, and produce premature wrinkles; they are, therefore, better avoided. Mucilaginous cosmetics, such as barley water, oatmeal, &c., have not this inconvenience; they render the skin more supple, softer, and more polished. Pastes and ointments sometimes produce good effects in certain states of the skin. They are generally laid on the face and hands, and remain on all night, contributing to restore the suppleness and elasticity of the skin; but the fatty substances that form their bases ought to be well purified. Some consider the wax that sometimes enters into the composition as too drying and irritating, and recommend fresh cream as better. As a general rule, it is prudent to avoid the use of all cosmetics the composition of which is a secret or unknown, which will, of course, exclude all those which are advertised with high-sounding names. Some of these produce astonishing effects at first, but ultimately ruin the skin, destroying its natural functions, and, consequently, seriously injuring health.

6016. *All medical men teach that the best way of improving the skin is to improve the health generally by temperate living and moderate exercise*, and this will be evident by considering its structure. It is well known that the skin consists of the *outer* or *scarf skin*, called by anatomists the *cuticle* or *epidermis*, and the *inner* or *true skin*, named *dermis*. *The first* is a very thin membrane, transparent, and without blood-vessels; it has no nerves, consequently no sensation, and may be pared or cut with a knife without any pain; it is that which rises in blisters. *The true skin* beneath is much thicker, and is entirely filled with nerves, and the extremities of an infinity of minute blood-vessels, by which the blood which comes from the heart to the skin returns back again, the turn in the circulation being at the surface. That these nerves and vessels are excessively numerous is shown by the prick of a needle in any part giving pain, and by the blood which issues from some very minute vessel having been pierced. The change in a large portion of the circulation taking place, as we have stated, in the skin, it is obvious that whatever impedes in any degree the healthy action of this organ must affect the whole system, as far as the circulation is concerned; and it is to preserve its most important functions that the use of the bath, friction, and similar processes are resorted to. These minute blood-vessels approach very near to the surface of the skin, and the cutis being transparent, they give the flesh colour, which is more ruddy in some places than others, as upon the cheeks, from their greater size or number in that part; and the want of healthy action in these vessels is indicated by the paleness of the complexion. In the skin there are, likewise, innumerable minute pores, by which the insensible perspiration exudes.

Paints for the Face.

6017. Since this species of decoration, once so general, is now almost out of fashion, it is unnecessary for us to inveigh against it; whether there are not cases where the practice may still be allowable, we shall not determine, but proceed to point out the materials that are usually employed, with cautions against such as are deleterious.

6018. *Pearl white* is a preparation of bismuth, which is sold under that name, but which is extremely injurious to the skin. It is also liable to turn black if exposed to the fumes of sulphur, or the sulphureted hydrogen of certain mineral waters, such as the Harrowgate. On this subject an anecdote is told. A lady thus painted was sitting in a lecture-room, where water impregnated with sulphuretted hydrogen was handed round for the examination of its odour. On smelling the liquid, the lady became *black in the face.* Every person was, of course, alarmed at the change, till the lecturer explained the cause of the accident. The lady received no serious injury, but had a salutary lesson.

6019. *Ceruse*, a white paint, was formerly much used, but now it is never employed, from its dangerous properties being known. It is a carbonate of lead, and the same as *flake white*, or the *white-lead* used by painters. It is poisonous, and extremely pernicious to health when put on the skin; it is also liable, when exposed to sulphuretted hydrogen, to turn black, and, of course, to produce lamentable accidents. It ought to be entirely excluded from the toilet. As an instance of ceruse turning black, as well as pearl white, may be mentioned that, in a receipt for changing the hair to black, it is directed to mix this with the pomatum.

6020. *Pearl powder* is the name of a cosmetic that was formerly much in request; and from its name it ought to consist of pearls ground to powder; but this would evidently be too expensive for common use. It is, we believe, made of briançon, or French chalk, powdered fine, and perhaps mixed with pearl white, or bismuth; and if the latter is added, it will be liable to turn black. (See "Pearl White.") The French chalk alone is harmless.

6021. *Carmine* is a well-known red paint, prepared by precipitating the colouring matter of cochineal upon alumina, and is perfectly harmless if genuine. Different qualities of carmine are sold in the shops, distinguished by numbers, and having various prices. As the manufacture is in few hands, it is kept secret, and it is not well known what are the causes of these differences of colour; but they are supposed to be owing either to the greater quantity of alumina, or an adulteration by vermilion. The latter is a poisonous substance, a preparation of mercury and sulphur, that ought in every form to be entirely excluded from the toilet.

6022. *Cochineal* is the red juice of an insect peculiar to Brazil, the *Caccus Cacti*, and carmine is prepared from it in the following manner: Boil 1 lb. of cochineal, powdered, and 6 oz. of alum in 40 lbs. of water; strain the decoction; add ℥ss. of chloride of tin, called dyers' spirit; and after the carmine has precipitated and settled, decant the liquid, and dry the carmine in a gentle heat.

6023. *Rouge* is a well-known red paint for the face, so named from the French word for red. There are several kinds of rouge, but they are all composed of some vegetable colour, and talc, or powdered French chalk. The most common kind of rouge is produced from the colouring matter of the safflower (*Carthamus tinctorius*). The flowers are digested in a weak solution of carbonate of soda, which extracts the colour; and to precipitate this in the form of a fine powder, lemon juice or pure vinegar is added; but, previously, some fine carded cotton wool is put into the vessel for the colour to be precipitated upon. The cotton is then washed in cold water, to separate some yellow colouring particles, and a fresh solution of carbonate of soda is poured upon it to take up the colour, now of a pure red. The colour is then precipitated again, by more acid, upon a layer of finely-powdered talc; and afterward it must be triturated with a few drops of olive oil, to give it smoothness and fatness. The fineness of the talc and the proportions of the colouring matter occasion the difference in the price of the article.

6024. *Another kind of rouge* is made by reducing French chalk to a fine powder, and triturating it in a mortar with carmine. As some makers of rouge sometimes add vermilion to the carmine by way of adulteration, it will be well to apply a chemical test for that, as it is dangerous: if there be any considerable quantity, the weight will discover the adulteration, vermilion being a very heavy substance. Those who wish to make their own rouge may easily rub the briançon, or French chalk, in a mortar with good carmine.

6025. An inferior rouge is made by employing the colouring matter of Brazil wood or sandal wood. It is difficult to distinguish these among the specimens kept in shops; and the venders themselves only know the articles by the beauty of the colour, and the prices. It requires different tints to suit different complexions; and trial alone can determine which ought to be preferred, if any should be used.

6026. *Portuguese dishes*, or *rouge dishes*, are small dishes containing paint of a very pale pink hue, said to be a beautiful application; but what is made in London is of a dirty colour. The genuine dishes are rough on the outside.

6027. *Chinese wool* contains a very lovely colour; but an inferior kind is generally mixed in a parcel with the best. The colour is very fugitive.

6028. *Spanish Wool.*—Of this there are several sorts. The best comes from Spain: an inferior kind is made here. The colour is from cochineal.

6029. *Chinese Boxes of Colours.*—Little japanned boxes are sometimes brought from China, containing materials for adorning the face—black for the eyebrows; red for the face; and a white powder, said to be real pearl powder.

6030. *With respect to red paints*, vegetable reds alone are safe to use; they are dyeing substances, and are harmless; such as those made from cochineal, safflower, carthamus, sandal wood, and Brazil wood; but the mineral reds, such as minium or red-lead, and vermilion or cinnabar (a sulphuret of mercury), are poisonous, and ought to be entirely excluded from the toilet, together with every composition into which they enter as an ingredient. All these metallic preparations, and also ceruse, or white-lead, destroy the texture of the skin, cause wrinkles, and compel those who begin their use to continue the practice, although dangerous. The consequence of this is nervous affections, and perhaps palsy.

CHAPTER IX.

SUBSTANCES USED AS PERFUMES.

6031. The use of perfumes is of Eastern origin. They were much used among the Hebrews and Persians, and likewise among the Greeks and Romans. In Eastern countries, at present, it is the custom to compliment distinguished guests by sprinkling them with rose and other sweet-scented waters; and to burn incense, aloes wood, and other perfumes in silver censers, or to throw them on a tripod with burning coals; and this is sometimes done as a sign that it is time for strangers to take leave.

As the nervous system is strongly affected by the volatile drugs made use of as perfumes, medical men now condemn their general use as prejudicial to health; and they are among us limited to particular occasions, or to be employed in dress.

6032. *The substances used as perfumes* consist of aromatic gums, resins, and balsams; aromatic leaves, flowers, fruits, and roots of plants, or woods; also, animal perfumes: and the art of the perfumer is the preparation of various products from them, as pomades, essential oils, or essences, distilled waters, pastes, pastils, &c. We shall first describe the substances themselves from which these are prepared.

Sect. I.—GUMS AND BALSAMS.

6033. *Frankincense*, sometimes called *olibanum*, though the last is somewhat different, is the *incense* used in Roman Catholic churches, and was used for the same purpose by the ancient Egyptians and Israelites. It is a gum-resin that distils from a tree, the *Junipera Lyciæ*. The best comes from Syria and Arabia. It is in pale, yellow drops, like mastic, and when laid upon coals, or red hot iron, it gives out a sweet-smelling odour. It is employed in pastils, but is very liable to be adulterated with turpentines.

6034. *Myrrh*, an ingredient in many tooth-powders, is a gum-resin that exudes from a small scrubby tree that grows in Arabia Felix, the *Balsamodendra myrrha*.

6035. *Gum benjamin*, or *benzoin*, is a resin extracted from a tree called *Styrax benzoin*, which grows in Siam and the Indian islands, Java, Sumatra, &c. It has an agreeable smell, somewhat like vanilla. It is much used in fumigating pastils, and in certain varnishes which exhale an agreeable odour when heated by the hand. It is the perfume used in court-plaster, and in perfumed sealing-wax.

6036. *Storax* is a gum-resin that exudes from a tree called *Styrax officinale*, that grows in countries bordering on the Mediterranean, and likewise in America and India. It is a valuable perfume for some purposes, resembling benzoin, of which it contains 1·4 per cent. Genuine storax is very difficult to procure; what is usually had is an inferior kind that comes from Holland.

6037. *Balsam of Peru* is a resin used in perfumery, and is obtained by making incisions in a tree which grows in Peru and Mexico (*Myroxylon ceriferum*), or by evaporating a decoction of its branches and bark. It is brown, and of the consistence of turpentine, has an acrid, bitter taste, but an agreeable colour. It is high priced, and, consequently, often adulterated. It contains a portion of benzoic acid.

6038. *Balsam of Gilead* is a turpentine, not a balsam; it is a perfume much esteemed by the Turkish ladies, but scarcely known here. It is obtained from a tree, the *Amyris Gileadensis*, a native of Abyssinia; but the balsam is generally procured from Gilead, in Judea, whence the name.

6039. *Gum elemi* is a gum-resin, procured by incision from *Amyris elemifera;* yields a sweet odour when burned.

6040. *Labdanum* is an unctuous resin, of an agreeable odour, found upon a plant (*Cystus creticus*) which grows in Candia and Syria. The genuine sort is rare, very heavy, and light brown; the impure kind is generally darker.

6041. *Dragon's blood* is used in tooth-powders. It is obtained by macerating and steaming the fruit of the *Calamus draco.* It is in round masses, of a brownish red.

6042. *Gum copal* is a resin which exudes from two trees, of which one grows in India and the other in America. It is used in pastils.

Sect. II.—aromatic leaves, flowers, roots, and woods.

6043. *Orange flowers* cannot be had in sufficient quantity in this country, but are abundant in the south of Europe, and are also procured in tolerable quantity in the vicinity of Paris, where they are collected every morning from private and public establishments. They should be made use of immediately they are gathered from the tree, as they very soon lose their fine odour.

6044. *Rose Leaves.*—The flowers of the damask and the red rose yield a strong perfume, either dried or by distillation. They should be gathered in dry weather; and if they are to be salted for winter use, this should be done as soon as possible after they are picked from the stalks.

6045. *Lavender Flowers.*—These are used for making oil of lavender, and lavender water. They should be gathered dry, and kept in paper bags; if put into boxes they are apt to heat and spoil. Their use, put among linen, is well known.

6046. *Jessamin flowers* are abundant only in warmer climates than ours; the odour of what grows here is sweet, but not powerful. They are so delicate that they will not bear the heat of distillation; and their perfume is collected by means of wool, in the manner described under "Still-room." They do not preserve their perfume long when dried.

6047. *Violet Flowers.*—The same observations apply to violets as to jessamin.

6048. *Rosemary.*—The leaves and flowers are used in making Hungary water and oil of rosemary. Young plants produce the best flowers.

6049. *Marjoram, lemon thyme,* and *basil* should be preserved as lavender.

6050. *Myrtle leaves and peach leaves* are used in herb snuff.

6051. *Tonka bean,* properly *Tonquin bean,* is used here to perfume snuff; but in the West Indies and America it is employed to put among clothes and to keep away moths. The aroma of the seed is owing to a volatile oil which it contains.

6052. *Orris* or *Iris root* comes chiefly from Florence. It is white, and has a fragrant smell, very like violets. It is used in various ways.

6053. *Calamus root* belongs to the *Acorus calamus,* or sweet flag. It grows in this country in ponds. The smell is powerful, but coarse.

6054. *Cyperus Root.*—The best kind comes from Florence; one kind, nearly equal to it, long-rooted cyperus, is found wild in this country. When first powdered, the scent is weak, but by keeping it becomes stronger. It is used in making the cyperus powder of the perfumers.

6055. *Cedar.*—This sweet-smelling wood is in great request for drawers for wearing apparel, and the shavings are used to keep away moths.

6056. *Rhodium wood* is said to be the wood of a Chinese rose tree; its perfume is similar to that of roses, and is sometimes used with orris root. If bought rasped, it is probably adulterated.

6057. *Yellow sanders wood* has a smell resembling that of a green citron; from it an oil is prepared having a powerful odour.

6058. *Cinnamon and cloves* may be reckoned among the perfumes.

6059. *Various mixed odoriferous substances powdered,* called *sachet powders,* are put as perfumes among linen and other articles of dress in wardrobes or drawers; one of them is the following: Take the dried leaves of roses, pinks, hyacinths, lavender, balm, stock, gilliflower, or any other sweet-smelling flowers; dry them in the shade; then powder them coarsely, and mix them with powdered nutmeg, mace, or a very little musk, and add to them some powdered sugar to preserve them. Put all this into bags of taffeta, and lay them among the wearing apparel, to give a perfume and to drive away moths.

Another.—Lavender, thyme, marjoram, sage, vervain, rosemary.

Sect. III.—animal perfumes.

6060. *Musk* is a concrete substance found in an animal having a near affinity to the deer tribe, the *Moschus moschiferus,* a native of Thibet, China, and Siberia. The musk-deer is a timid animal, and rarely appears during the day; consequently, the musk collectors watch and surprise it at night. The best musk comes from China; and, to have it genuine, it should be purchased in the natural bag, or pod, as it is very often adulterated. The Bengal musk is inferior, and that from Russia the worst of all. The hair on the pod of the best musk is a fawn colour, that on the inferior a dirty white. A variety of musk is found in the musk-rat of Canada, an animal about the size of a small rabbit. Musk is of a bitter taste, and of an odour more powerful than anything known; substances in its neighbourhood become strongly infected by it, and, when once perfumed with it, long retain the scent. It has been known to affect chests of tea placed at a considerable distance, even though both had been packed up in leaden boxes; for which reason, the East India Company gave an order not to import musk and tea in the same ships. Many persons dislike the odour. It has the property, when employed in very small quantities, of augmenting the scent of other substances without imparting its own.

6061. *Ambergris* is much used in the composition of perfumes; its origin is not yet satisfactorily ascertained, but is supposed to be a morbid concretion in the spermaceti whale. It is usually found floating on the sea or on the seacoast, and comes to us from the East and West Indies, but sometimes also from the northern seas. It is generally found in small pieces, but occasionally in masses of fifty or a hundred ounces. Ambergris has a good deal of resemblance to amber; but it is opaque, fatty, and inflammable, remarkably light, melts readily when heated, and is scarcely soluble in spirits of wine. There are several varieties; gray, and black, or dark brown; the former is the best, easy to break, and lightest; the latter is harder and heavier, and has very little smell. This substance is very liable to be adulterated by an admixture of wax, gum, storax, &c., by which the odour, which is agreeable, is impaired. It is generally joined with musk. Its odour is so strong, that if the box in which it is contained be left open for five minutes, it will perfume the whole chamber.

6062. *Civet* is a substance taken from the civet cat, and having a perfume approaching to that of musk and ambergris. Its consistence is like that of honey; it comes from the East and Africa, and is brought to us chiefly by the Dutch. It is very liable to adulteration by honey. It was chiefly used for perfuming wash-balls, &c., but it is little employed at present.

6063. *Spermaceti* is much used by the perfumer in making pomatum. cold cream, &c. When good, it has no rancid odour.

Sect. IV.—ESSENTIAL OILS, OR ESSENCES; PERFUMED SPIRITS AND WATERS.

6064. The nature of oils, or essences, has been already described in Book VII., Chap. VII., Sect. X. Some of what are called essences by perfumers are essential oils diluted with alcohol; or they are expressed oils impregnated with odorous essential oils.

Attar of roses, sometimes called improperly *otto of roses*, is the essential oil of the rose, and the most fragrant and precious of any known: it comes from India in small gilt bottles, each containing an ounce. The smallest drop on a pair of gloves will perfume them for a long time. An inferior kind comes from Barbary. The manner of preparing it is described in Book XX., Chap. III.

Oil of roses is made here, but this is merely spirit strongly impregnated with the essential oil of roses.

Oil of rhodium in fragrance resembles roses. It is prepared from rhodium wood *by distillation*, and comes chiefly from the Levant; it is of a pale brownish red colour. The oil of sandal wood is sometimes sold for it.

Oil of lavender is made in this country as well as in France, and it is said that our lavender is richer in perfume than the foreign. It is always best during the year in which it is made, and does not keep long.

Oil of rosemary comes chiefly from Italy; but the English is considered to be better. It is used in making Hungary water, and in scenting soaps.

Oil of cloves and oil of cinnamon are occasionally used by the perfumers; they are made in the Indian islands.

Oil of coriander is very fragrant, but scarce; it costs three guineas an ounce.

Essence of rondatella, much recommended for perfuming handkerchiefs, &c.; it retains its perfume for several days.

Essence of jessamin is a fixed oil saturated with the aroma of the flowers of jessamin. It is expensive, as it comes from India, and some from Italy; it is little known here. The best has a double impregnation of the flowers, and will keep several years; but that which has only a single impregnation will not keep above a year.

Essence or oil of orange flowers, called neroli, is made abroad, as it cannot be obtained but from the fresh flowers of the orange.

Essence of bergamot is prepared from a species of lemon, *Citrus limetta*. The essence is extracted by pressure from the rind of the fruit; it is extremely common, and is brought from Italy.

Oil of citrons and of lemons; oil pressed from the peel of the citron and lemon

Essence of Violets.—What is sold under this name is said to be from the root of the Florentine orris, and has an odour like violets.

Essence of jonquil, prepared from narcissus flowers.

6065. *The spirits of the perfumer* are odoriferous substances dissolved in spirits of wine, whether the essential oils of plants or other matters, or spirit of lavender, ambergris, &c. There is much confusion in the mode of designating these preparations, some calling them waters; thus, Hungary water and eau de Cologne, though named waters, are spirituous preparations. The manner of preparing these will be given in Book XX., "On the Still-room."

6066. *List of perfumed spirits :*

Spirit of bergamot.	Esprit de Venus.	Spirit of citron.
" lavender.	" millifleurs.	" cloves.
" ambergris.	Eau de Cologne.	" goujac.
" musk.	Hungary water.	" jonquil.
" roses.	Spirit of tuberose.	" pinks.
" jessamin.	" cassia.	" orange.
" mint.	" violets.	Eau de lis.
" benjamin.		

Some of these are used for perfuming wearing apparel, as handkerchiefs, shawls, &c.; others are partly remedial, and are employed by apothecaries.

Tincture of roses is easily made, by taking the leaves of the common rose and putting them, without pressing, into a bottle. Pour some good spirits of wine upon them; close the bottle, and let it stand until it is required for use. This will keep for years, and yields a perfume little inferior to attar of roses.

6067. *It is essential that the rectified spirit, or spirit of wine, used in making perfumes should be perfectly good.* To try its purity, rub a little in the palm of the hand very quickly, until it has completely dried away; if the smell it leaves be agreeable, it is good; but if it be empyreumatic and nauseous, the spirit is foul, and should not be used.

6068. *Perfumed or distilled waters* consist of water having dissolved in it a small quantity of odoriferous essential oils, and the manner of preparing them will be given in Book XX. As an example, we may give here honey water:

Honey Water.—Take two pounds of the best clarified honey; add a little water, and melt it in a water-bath; put in rose petals, orange flowers, the rind of two lemons, some coriander, vanilla, and cloves: add then a sufficient quantity of rectified spirit of wine; bruise the ingredients again, and add another pound of honey, and mix the whole well. Suffer this to infuse for eight days, and then distil with a water-bath.

Rose Water.—The manner of preparing this will be described in Book XX., "Still-room." That sold in the shops is chiefly made from rose petals preserved with salt.

6069. *List of perfumed waters :*

Lavender water.	Portugal water.	Jessamin water.
Rose water.	Eau de millifleurs.	Myrtle water.
Honey water.	Eau sans pareil.	Cordova water.
Hungary water.	Eau de Carmes.	Eau de mousseline.
Bergamot water.		

SECT. V.—PASTILS.

Pastils are small conical shapes made up chiefly out of aromatic resins, which, when set on fire, give an agreeable odour for the purpose of perfuming the apartment; and it is by some persons *erroneously* supposed to correct the bad air which it may contain. (See Book III., "On Ventilation.") They are made by mixing gum benjamin, storax, labdanum, frankincense, or any other similar odoriferous gums, finely powdered, into a paste with gum water, and powdered charcoal and saltpetre. When the paste is stiff enough, it may be rolled up into the conical shapes, about three quarters of an inch long, and dried.

6070. *Pastilles à la Rose.*—12 ounces of gum, 12 do. of olibanum in tears, 12 do. of storax, 8 do. of nitre, 16 do. of powder of pale roses, 3 pounds of charcoal powder, 1 ounce of essence of roses.

6071. *Pastils of Orange Flower.*—12 ounces of gum galbanum, 12 do. of olibanum in tears, 12 do. of storax 8 do. of nitre, 1 pound of pure orange powder, 3 pounds of charcoal powder, 1 ounce best oil of *neroli.*

6072. *A few drops of the oil of sandal wood,* dropped on a hot shovel, diffuses a most agreeable balsamic perfume throughout the atmosphere of sick-rooms, or other confined apartments. Frankincense may likewise be used to perfume an apartment. Pastils may be burned upon anything that will protect the table; but the most elegant mode is to place them in a pastil-stand sold for the purpose.

6073. *Highly-concentrated smelling salts* are, in some respects, preferable to pastils, where fumigation is required. It is sufficient to leave out the stopper of the bottle containing the salts for a short time, to perfume a chamber.

SECT. VI.—POMADES, OR POMATUMS.

6074. These are preparations for softening the skin and hair, and consist of fats or oils with the addition of some perfume. It is necessary to choose such fats as do not become rancid; the best are clarified *beef suet,* or *clarified beef marrow,* and *hogs' lard.*

6075. *Beef or mutton suet and hogs' lard are clarified* from the raw materials by chopping them fine, and rolling them out to break the cells in which the fat is lodged, then melting the fat in a water-bath, or other gentle heat, and straining it while warm; it is then put into bladders to keep it from the air. Or it may be made by boiling it in water, and skimming it off when cold; but by this method it contains water, and does not keep so well as when melted by itself.

6076. *Purified beef marrow* is preferred by some perfumers to hogs' lard. It is purified in the same manner as the last and is thought by some to make the hair grow.

6077. *Veal fat* is used by some perfumers, as it will keep long.

6078. *Oil of cacao* is much used as a pomade by the ladies of Mexico, and by many of the African tribes, and is highly spoken of. In England, from the coldness of the climate, it grows too hard to be used by itself, but may be softened by an admixture of some pure oil, as oil of behn, or cold-drawn oil of almonds.

6079. *The expressed oils used by perfumers are, olive oil, oil of almonds, trotter* (neats' foot) *oil*, chiefly used in making cold cream, and oil of behn, expressed from behn nuts; this last is imported from Italy, and has the valuable property of not becoming rancid.

6080. *Common soft pomatum* is made of equal parts of beef or mutton suet and hogs' lard melted together; while they are liquid, put to it a little bergamot, or any other perfume that may be agreeable, and beat the whole well together, and then pour the mixture into pots.

Another Receipt.—Soak in water for two or three days half a pound of clean beef marrow and a pound of fresh hogs' lard, changing and beating it every day. Put it into a sieve, and when dry into a jar, and the jar into a sauce-pan of water. When melted pour it into a basin, and beat it with two spoonfuls of brandy; drain off the brandy, and add bergamot, or any other perfume.

Another.—An ounce of hogs' lard, one of beef marrow, one of spermaceti, and a pint of almond oil, melted together; add oil of bergamot and oil of roses, or any other perfume.

Hogs' lard alone, perfumed, will serve for pomatum for ordinary purposes, if it be required very soft; and oil of almonds and spermaceti melted together form a useful unguent for the hair; a little bergamot may be added.

6081. *Hard pomatum* may be made by melting together equal quantities of beef and mutton suet, the former being in the largest proportion, and making it up into rolls with paper round them.

6082. The French make a great variety of pomades; above twenty are sold by the perfumers in Paris.

Pomade à la rose.	Pomade au graisse d'ours.	Pomade au neroli.
" à la jonquille.	" à la citrouille.	" à la fleur d'acacia
" au jasmin.	" en crême.	" au barjoin.
" à l'œillet.	" à la moëlle de bœuf.	" au narcisse.
" à la fleur d'oranger.	" au concombre.	" à la fluer de lavande.
" à la digitale.	" à la frangipane.	" aux limaçons.
" à l'heliotrope.	" au baume.	" au lilas.

Highly-scented pomades are often preferred to scented oils.

6083. *Some pomades are made by infusion* in those southern countries where odoriferous flowers are abundant. Beef suet and hogs' lard are melted together; to this the petals of roses, orange flowers, or other sweet-scented flowers are added. This remains at rest for twenty-four hours, and it is then remelted and well stirred. It is next put into canvass bags, and pressed, to separate the solid from the fluid part. This process is repeated with the same fat several (perhaps ten or twelve) times, till the pomade has enough perfume. In this process it requires 3000 lbs. of fresh rose petals to make 500 lbs. of good pomade.

6084. *Pomades are also made without infusion*, as those of jessamin, tuberose, jonquil, narcissus, and violet. A square frame, called *tiame*, is made of four pieces of wood, well joined together, two or three inches deep, into which a pane of glass is laid, resting upon inside ledges, even with the bottom. Upon the surface of the pane the simple pomade of hogs' lard and suet is spread with a pallet-knife; and into this pomade the sweet-scented flowers are stuck, fresh, in different points, each successive day during two or three months, till the pomade has acquired the desired richness of perfume. The above-described frames are piled closely over each other. Some establishments at *Grasse* possess from 3000 to 4000 of them.

6085. *An experienced perfumer* states that, notwithstanding it is the custom to employ the flowers themselves in making perfumed pomades in those countries where the flowers are abundant, yet they can be made equally well, and with much more expedition, with the essences of the flowers; and these have this advantage, that pomades can be made when the flowers cannot be procured; also, that the perfume can be communicated with more precision by means of the essence, since, in the other process, the mucilaginous portions of the flowers sometimes alter the odour.

6086. *Pomades are likewise made of compound perfumes;* as *Roman pomade*, or pomade à la vanille, which consists of twelve pounds of pomade à la rose; three pounds oil à la rose; one pound best vanilla; six ounces bergamot.

6087. *Pomade au Pot Pourri.*—This pomade is made by adding to a fatty basis the essences of several odoriferous substances, and may be varied at pleasure. It retains its odour very long.

6088. *An agreeable perfumed oil may be made thus:* Dip cotton wool in clear olive oil, and, having procured a tall glass vessel, lay the cotton alternately with jessamin flowers. In a few days the flowers will have imparted their perfume to the oil, which may then be squeezed out for use; and the cotton may be employed by laying in band-boxes or drawers where perfume is required.

6089. *Cold Cream.*—This *pomade en crême* is very useful for chapped hands or face, and softens the skin. Melt together in a water-bath eight ounces of fine neats' foot oil or almond oil, three ounces spermaceti, and one and a half white wax. When thoroughly melted, pour the whole into a pan, which in winter must be kept very warm by the fire. Then with a wooden spatula beat the whole constantly, until it becomes a very uniform white body; pour into it half a pint of rose or orange-flower water, with about a quarter of an ounce of spirit of ambergris, or bergamot, or any other perfume. Next beat the mixture well again, until the whole of the water and spirit is absorbed by the unctuous substances. It ought then to be as white as snow, whence the name cream. Pour it now into pots, and keep it cool. If made in cold weather, all the materials must be warmed as they are mixed, or the whole will be lumpy. A marble mortar, if at hand, is convenient to mix it in.

Another.—Melt together four ounces of spermaceti and one of lard; add bergamot and rose water.

Another.—Melt one drachm of white wax, one of spermaceti, and two ounces of olive oil; add two ounces of rose water, and half an ounce of orange-flower water.

Another.—Melt together equal parts of almond oil and white wax. Add to the mixture, put into a marble mortar or strong glass basin, a few drops of some perfumed water, as rose, orange, or elder-flower water, and rub them together with a pestle till they are thoroughly incorporated; then add more and more drops, rubbing all the while, till the mixture, when cold, is of the consistence of cream.

6090. *Lip Salve. Pomade pour les Lèvres.*—This is a preparation extremely useful as a remedy for chapped lips, by applying it pretty freely at bedtime. It is made of equal parts of almond or olive oil, and the best white wax. Melt the wax in a clean gallipot, set at the side of the fire, then add the oil. It is customary to colour the salve by adding a little alkanet root suspended in a piece of muslin, while the salve is hot, and melted, or a little carmine; but this colouring has frequently the inconvenience of reddening a cambric handkerchief if accidentally applied to the lips. Some perfume is also generally added, as bergamot, oil of lavender, oil of cinnamon, &c., but it is not essential.

Pastes.

6091. To soften and improve the skin of the hands and arms, some use pastes of various kinds.

6092. *Almond paste* is one of those most generally used; the oil of the almond has some effect in rendering the skin supple. One receipt is, beat in a mortar four pounds of sweet almonds, blanched and dried, with lavender or Hungary water. Add to this one pound of white drained honey, two ounces of oil of jessamin, half a pound of the best almond powder, and four ounces of orris powder; the whole to be well incorporated. This will keep, if no eggs or milk be added. Almond powder is made by extracting the oil from the almonds by pressure, then drying what remains, and grinding it.

Another Way.—Take one pound of sweet almonds, a quarter of a pound of crumb of bread, and the yolks of two eggs. Skin the almonds and pound them in a mortar, and sprinkle them with vinegar, that the paste may not turn to oil; add the crumb of bread and the eggs, and moisten the whole with brandy, diluted with an equal quantity of water; mix all this well together, set it over a slow fire, and keep stirring it all the while, so that it does not burn to. Add the brandy and water till the consistence is right.

Another.—Warm in three separate vessels two ounces of sweet almonds blanched and pounded, three drachms of fine white wax, and three drachms of spermaceti. When these are melted, pour them together, and stir them well with a wooden spatula, and throw them into some water; keep stirring in the water, which you must change frequently till the pomade becomes very white. Keep it in rose water, or spring water, which must be changed every day.

Liquid Almond Paste.—Mix six pounds of honey, six pounds of paste of bitter almonds, twelve ounces of oil of bitter almonds, and twenty-six yolks of eggs. The honey should be heated apart and strained; then the almond paste kneaded with it; and, lastly, the eggs and almond oil by degrees.

6093. *Bean flour is said to be an excellent detergent for the hands.* Take half a peck of white and well-dried split horse beans; having separated them from their shells, or skins, beat them as fine as possible in an iron mortar, or have them well ground in a mill. Pass the powder through a fine sieve. About four pounds of powder will be obtained from the above quantity of beans.

6094. *Paste for chapped Hands.*—Wash a quarter of a pound of fresh hogs' lard in water, beat it up with the yolks of two new-laid eggs and a large spoonful of honey. Add as much almond paste, or fine oatmeal, as will work it into a paste.

6095. *Almond oil* is procured by expression from bitter almonds, or from old Jordan almonds, by heat. Cold-drawn almond oil is obtained in the same way from fresh Barbary almonds. It keeps longer than the common oil.

6096. *Milk of almonds* is used to bathe the face, and is made thus: Bruise some sweet almonds in a mortar, and add water by slow degrees in the proportion of a pint to twenty or thirty almonds; put to this a piece of sugar, to prevent the separation of the oil from the water, rubbing assiduously. Pass the whole through a flannel, and perfume it with orange-flower water.

BOOK XX.

STILL-ROOM, AND THE MANNER OF FITTING UP A DOMESTIC LABORATORY.

6097. Time was, when in the *still-room* "strong waters," "distilled waters," and "cordials" were drawn and dispensed as specifics for maladies to guests and dependants, as well as to poorer neighbours. Many of these preparations have gone out of use, and others may be purchased more conveniently, and even cheaper, than they could be made at home. We are far from recommending the complete revival of this part of domestic economy; yet we cannot, with propriety, omit the still-room altogether, since it may be extremely useful, on occasion, to certain families residing in the country, at a distance from medical practitioners, and where economy is an object; but the information we give is rather with the same view as that with which we have explained the manufacture of spirits, and not to teach accurately the art of preparing what is now seldom attempted at home. We might observe, however, that a *still-room* might be more elegantly considered as a species of *chemical laboratory*, or a private culinary room, where certain processes may be carried on that would not agree with the bustle of the kitchen, and where the superiors of the family might make experiments and trials without infringing upon the convenience of the cook, or interrupting her regular avocations. With this view it might be fitted up in a very neat and useful, though not extensive plan, with convenient apparatus, so as to furnish a source of amusement and instruction; and we shall proceed to describe the principal apparatus required for such an apartment, as well as to explain some processes which are likely to be performed there, and the usual terms used in speaking of them. All this may, to some persons, appear to be encroaching too far upon the province of the chemist and *his* laboratory; but it should be recollected that many processes in domestic economy are *strictly chemical*, and that it is only by borrowing a little from practical chemistry that they can be improved. We wish to see our improved still-room become *the domestic laboratory;* in which, likewise, such operations as pickling, preserving, &c., may be carried on by the housekeeper and still-room maid. Adjoining to this might be the *medicine closet.*

Some of the principal operations in the still-room were the making of *liqueurs* and the preparation of *distilled waters*. The first we have already described in the Chapter on Spirituous Liquors, Book VIII., Chap. VIII.; and we shall presently treat of what are called distilled waters, and the essential oils of plants, which contain the perfume or odoriferous principles essential to perfumery, and which are procured by distillation. But first it will be necessary to describe the apparatus made use of, together with the principal operations usually performed in the kind of laboratory we have talked of.

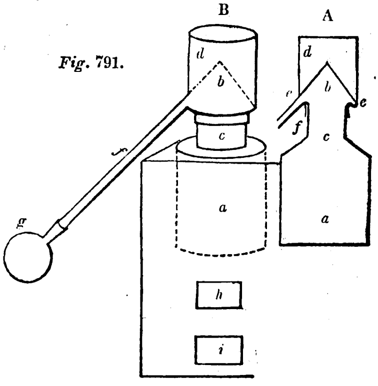
CHAPTER I.

APPARATUS FOR DISTILLATION.

6098. An essential part of the apparatus of the still-room is, of course, the *still;* but having already described the common still in Book VIII., Chap. VIII., "On Spirituous Liquors," we refer the reader to its explanation in that place.

6099. *The vessel called an alembic* is the oldest that was invented for the purpose of distillation. It is still employed; and as, from its simplicity, it has some advantages over the common still, we shall describe it. A, *fig.* 791, is a section of the alembic, and B is a view of it as fitted up. *a* is the body into which the materials are put, and to which the fire is applied; *b* is the head, which is in the form of a cone, and fits on the neck, *c*. The vapour rising out of the body fills the conical head, and is there condensed by means of a vessel, *d*, full of cold water, which surrounds it, called the refrigeratory; but instead of any of it falling back again into the body of the still, as it is apt to do in the common, or swan-necked still, it is stopped by a channel, or groove, *e e*, all round the inside of the head, which collects it; and from this groove a pipe, *f*, conducts the condensed product of the distillation into the receiver, *g*. *h* is the fire-door, and *i* is the ash-pit door. The cold water in the vessel *d* must be frequently renewed by a pipe leading to it from a cistern, and there must be a small pipe to carry off the warm water.

Fig. 791.



The simplicity of this apparatus would enable a tinman to make it who could not make the head of a common still: the worm of the latter is expensive, and, from its form, does not admit of being easily cleaned out, which proves very inconvenient when some oily matters have passed through it; whereas the beak of the alembic, being straight, is easily cleaned.

6100. *For some nice purposes, the alembic is made of glass in the form* A, *fig.* 792; but as this is expensive, and very liable to be broken, its use is generally superseded by that of the retort.

6101. *The Moor's head* is another form of still that has been used, and is found convenient for distillation on a small scale. *a, fig.* 793, is the body of the still, to which the

Fig. 792.

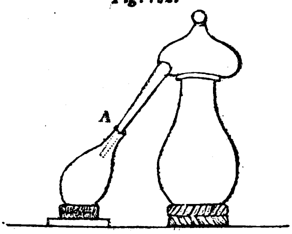


Fig. 793.

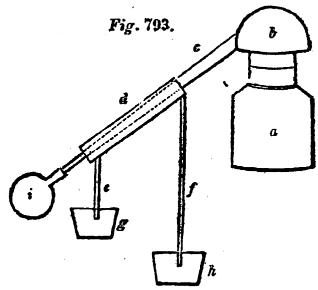
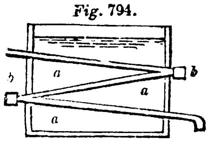


fire is applied; *b*, the head, of a semi-globular form, which has a groove all round the inside in the same manner as the alembic; *c* is the nose of the Moor's head, through which the vapours pass from the head: to condense these, the nose is surrounded by another larger tube, *d*, kept always full of cold water by a very ingenious contrivance. *e* is a pipe proceeding from the lower end, and *f* is a longer pipe from the upper end: these two pipes form, with the tube, *d*, a siphon, and as the short leg, *e*, is immersed in a vessel of cold water, the water will rise, on the principle of the siphon, pass to the upper end of the tube, *d*, in a continual stream, and descend by the longest leg, *f*, into the vessel, *h*. The pipe of the Moor's head is inserted into the receiver, *i*, for the product of the distillation. We have omitted the supports of these several vessels, as those can easily be imagined.

6102. Should it be preferred to have a tube in water, on the principle of the worm of the common still, a form which admits of being cleaned out is the following: *a a a, fig.* 794, is a straight pipe bent in angles, and laid in a vessel of cold water, in the same way as the spiral worm of a still; and the vapour passing through this is condensed in a similar way; but at the angles, *b b*, where the pipes join, there are caps that screw off, and admit the access of a brush, or similar instrument, to clean the pipes.

Fig. 794.

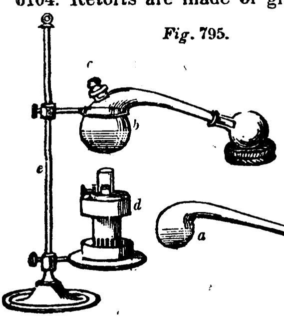


All these stills, the common still with the swan's neck, the alembic, and the Moor's head, when large, are fitted up in brick-work, and set in the manner of a copper for washing; but when they are small, they may be heated by a portable furnace of sheet iron, the fire part being coated with brick in the interior; very small ones may even be heated by a chemical lamp.

6103. *Vessels called retorts* are likewise employed for distilling on a small scale. The materials are put into the vessel called the retort, to which the heat is applied; and the fluid distilled, after rising in vapour and condensing, passes over into the receiver, which is kept cool.

6104. Retorts are made of glass or of earthen-ware. The first are used when no greater heat is required than what a lamp or a sand-bath will afford. It is a very elegant apparatus, because, through the transparency of the glass, the operation can be watched and examined. Great care is required in managing the heat, so as not to allow the substances to boil up and fill the neck. Some practice, likewise, is necessary to use them without breaking, to which they are very liable, particularly if a drop of cold water should fall on them while they are hot. *a, fig.* 795, represents a common retort; *b* is one tubulated at *c*, where an opening is provided with a ground glass stopper, to add occasionally fresh materials. If the heat of a furnace is required, the glass retort is coated with clay, or earthen-ware retorts are used.

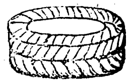
Fig. 795.



The lamp used for heating a retort may be a spirit lamp; but if more heat be required, then an Argand lamp, of a particular construction, called a *chemical lamp*, *d*, *fig.* 795, with a short copper chimney, instead of a glass one, is employed, and the retort is suspended on the ring of the stand *e*.

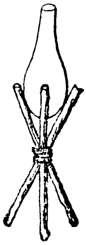
6105. *Circular bands worked of straw* are very convenient to place retorts, flasks, or basins upon, to prevent breakage, *fig.* 796. *Bladders* are used to tie round the necks of bottles, &c. Very thin caoutchouc is now prepared as an elegant substitute for bladder.

Fig. 796.



Stands for many vessels may be of three pieces of wood fixed together, as in *fig.* 797.

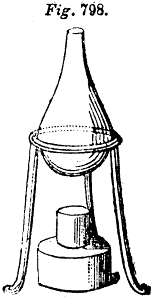
Fig. 797.



6106. *In distilling with the retort*, it is sometimes necessary to fix the neck of it into that of the receiver, so as to prevent any of the product of the distillation escaping at the joint, as in *figs.* 795 and 800. This is performed by putting round the joining a substance called a *lute*, which is composed of various materials, according to the nature of the distillation. For common lutes, where no great degree of heat is employed, a strip of linen dipped in paste or starch is sometimes sufficient. When stronger lutes are necessary, clay mixed with drying linseed oil may be used, or clay and sand: a paste of linseed meal is an excellent strong lute, but is so hard that it can scarcely be removed. Slacked lime and glue does not set quite so hard. Plaster of Paris will serve as a lute, and particularly if it be washed over with drying linseed oil after it has set.

6107. *The thin pint Florence flasks*, in which we receive olive oil from Italy, are extremely useful for many operations where heat is concerned, as their thinness enables them to resist sudden changes of temperature better than our flint-glass flasks; but they should be chosen as free as possible from knots and flaws, and should be carefully handled, as they are not strong. They have the advantage of being cheap, and may be procured of the oil-men. The wood-cut, *fig.* 798, represents boiling in a flask placed upon a stand made of thick wire. These flasks, when got from the oil-men, are generally oily. They may be cleaned by putting a little alkali in the water to wash them; but it is better to pour in a little strong nitric acid, or some oil of vitriol, and then heating them over a lamp; after that, everything will come away on washing with water.

Fig. 798.

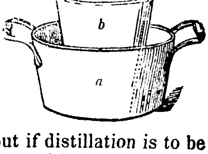


6108. In preparing distilled waters, or in distilling liqueurs, if the copper body of the still holds two quarts, it will be easy to draw off a gallon of liqueur at each distillation. To obtain the spirit in its utmost purity, the process of distillation must be conducted slowly and carefully, and the vapour that is raised condensed effectually. For this purpose, the refrigeratory, or worm-tub, should be supplied with cold water as fast as it becomes warm, and in winter ice may be used instead of water. If the heat applied is violent, the vapour will rise so fast as to blow off the head of the still, or the charge in the copper will boil over, pass into the worm, and spoil the process; also, by using too great a heat, the materials may be burned, and acquire an empyreumatic taste.

6109. *In many cases of distillation*, therefore, such as the preparation of essential oils, or the finer kinds of ardent spirits, &c., where an excess of heat might injure materially the products, instead of applying the fire directly to the vessel containing the substances to be distilled, these are placed in another vessel having in it some fluid or powder, through which the heat is communicated in a more gradual and uniform manner.

6110. *The water-bath*, or *balneum mariæ*, *fig.* 799, is a very ancient apparatus, which is used where the heat required does not exceed that of boiling water. *a* is a vessel half filled with water: another vessel, *b*, containing the substances to be heated, is placed in the water. As the fire is applied only to the outside vessel, the materials in the inner one can never be heated more than 212°, the heat of boiling water; and the heat will always be equal so long as the water boils; therefore there can be no burning to, as is often experienced when there is only one vessel, and that exposed to the open fire. In the wood-cut the inner vessel is supposed to contain some substance merely to be heated by this method; but if distillation is to be conducted in this manner, then the body of the still is to be immersed in the water.

Fig. 799.



The water-bath has another convenience, besides equalizing and limiting the temperature; it affords the facility of applying any required degree of heat below 212° to a substance in an operation; for it is only necessary to raise the temperature of the water to that degree, which may be ascertained by plunging a thermometer into it, and then immersing the vessel containing the substance into the water; and this degree of accuracy could not be attained in any other way. If it were required to know at what degree wax, or any resin, melted, the substance might be put into a thin glass tube, and the tube into the water of the bath, then raising the temperature of the water till the wax melted, the temperature might be ascertained by the thermometer.

6111. *A temporary water-bath may even be made* by a tin sauce-pan; but it is necessary to observe that the interior vessel should not touch the bottom of the exterior one, for it will then get heat from the fire, and be raised above that of the water. Should this be used for distilling with a retort, the neck may be supported by passing through a hole in a wooden cover to the sauce-pan.

A Florence oil flask, very well cleaned, may sometimes be used instead of a retort, if a bent neck be cemented to it. If it should be desirable to have the heat of the water-bath somewhat greater than 212°, that may be effected by using a saturated solution of salt in water, which will bear to be heated to 238°; oil, or mercury, or melted metals, will give much higher degrees of heat; but these are seldom used.

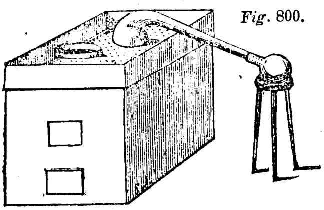


Fig. 800.

6112. *The sand-bath* is an analogous method of preventing the effects of a violent and unequal heat upon the still. Sand is put into a flat iron vessel, *fig.* 800, and the fire applied below to heat the sand; and the retort, or still, is placed in the sand in the same manner as in the water in the last method. The sand-bath differs from the water-bath in this respect, that the heat may be raised considerably above the temperature of boiling water. It is generally set in brick-work, and the fire is made to circulate backward and forward under the iron plate.

In chemical laboratories there is always a sand-bath large enough to receive several vessels for different operations; but when only a single vessel is employed, any iron pan capable of holding a sufficient quantity of sand may do. Where they are much used, sand-baths are best made of plates of cast iron; but these crack, unless made in separate pieces, and they are expensive, and, upon the whole, difficult to fit up, though the most durable. Those made of wrought iron are not liable to this inconvenience, though they are to another one, that of warping; but for domestic purposes they may frequently answer sufficiently.

6113. *Distilling in vacuo* is a modern improvement of great importance. It is a well-known fact that liquids boil, or are converted into vapour, at a much lower temperature when the pressure of the atmosphere is removed from their surface. This is easily illustrated by the air-pump. If a tumbler of water, lukewarm, be introduced under the receiver, and the air exhausted, the water will exhibit all the appearance of boiling, and be converted into vapour, although the actual temperature is not increased; that is to say, when the air is extracted, water heated only lukewarm will exhibit the phenomena of boiling or ebullition. This fact has been happily applied to distillation. The heat of boiling water, 212°, is capable of injuring many substances required to be distilled; but if the air be removed from the surface of the liquor in the still, the liquor will boil, and be raised in vapour, at a heat much lower. Where the air is removed, which is described by the term *in vacuo*, water boils at 90° instead of 212°, so that the fluid need never be heated more than 100°, or much above blood heat. This is particularly useful in medicinal preparations, as in distilling many extracts from vegetables which have their virtues destroyed, or much impaired, by the temperature of 212°; and it prevents all burned flavour, or empyreuma.

6114. This process has likewise been found particularly useful in boiling the sugar in refining. Instead of boiling at a heat of 218° or 220°, sirup requiring this to drive off the water is now boiled and evaporated, by means of the vacuum, at a very low temperature, which cannot burn the sugar; and thus a great saving is made. This has been already mentioned under "Sugar-making."

6115. *Many other improvements* have lately been made in the apparatus for distilling in manufactories, and several patents have been taken out, both in France and this country, for inventions of various degrees of merit; but the description of these does not enter into the plan of this work.

6116. *Sublimation* is a species of distillation in which the substance rises in a light flocculent form, instead of vapour, and condenses in form of a powder, as in the case of flowers of sulphur.

6117. *Rectification* is the repeated distillation of any fluid.

CHAPTER II.

VARIOUS PROCESSES PERFORMED IN THE LABORATORY.

6118. *When substances are to be comminuted*, or divided into small pieces, various methods are to be resorted to, according to the nature of the substances, and the use that is intended to be made of them.

6119. *Mortars* are well-known implements for pounding. When very hard substances are to be pounded, an iron mortar, with a pestle of the same material, may be conveniently placed upon a strong block of wood in a corner of the apartment. Sometimes a heavy hammer is required first to break the substances into pieces. For table mortars, those of brass are sometimes used, or, what is better and cleaner, Wedgewood's white-ware, or the Berlin, which is excellent. Some mortars are made of white marble, but they are less hard, though sufficiently so for ordinary purposes. For very nice purposes, small mortars are made of steel, agate, porphyry, and even of glass. For bruising succulent herbs, roots, and other recent vegetable substances, which do not require trituration, mortars made of box-wood or oak are sometimes used. To prevent substances from being scattered about while being pounded, the mortar should have a loose cover of wood or pasteboard, with a wide hole in it for the pestle; when such a cover is not at hand, a piece of pliable leather may be tied over it, or a clean cloth, held tight with one hand on the top of the mortar and round the pestle, may be used as a makeshift. After pounding, some substances are reduced to a still finer powder by rubbing or grinding with the pestle against the inside of the mortar. To pound properly in a mortar requires some practice, and should be learned by frequent trials; for this purpose, it would be well to observe the modes used by apothecaries. In general, a small quantity only at a time should be put into the mortar, otherwise some of the material may escape the complete action of the pestle. In many cases it is best to reduce the whole first to a coarse powder, and then to pound this over again finer, by small quantities at a time. Some soft substances, as chalk, require only bruising. Charcoal is best pulverized while hot: it may be ignited, and immediately introduced into a metal mortar, and rubbed to powder. Camphor has a toughness under the pestle, but is easily reduced to powder when moistened with a few drops of alcohol, or almond oil. Gum and resin, when pulverized, should be kept perfectly dry, or they will concrete again: they are best pulverized in cold weather; in summer they get too soft.

6120. *Trituration* and *levigation* mean a very minute division of substances in mortars of agate, or some very hard material, by a rotatory motion given to the pestle, or on a levigating stone, as a slab of marble or porphyry, or thick ground glass, *rubbing* or *grinding* the substances on it with a *muller*. In some cases it is necessary to add a little spirit or some liquid during the levigation, or reduction to an impalpable powder, to prevent its flying about.

6121. *Granulation* is the reduction of substances to visible grains. Salt may thus be made finer by rolling it with a rolling-pin. *Rasps* are necessary for reducing to powder woods, barks, horn, ivory, bone, &c. *Chipping* and *scraping* are likewise employed for the same purpose.

6122. *The emulsive seeds* cannot be reduced to powder except some dry powder be added to them. For the aromatic oily substances, sugar is the best addition.

6123. *Grinding with a mill* is also employed for many things, chiefly seeds, as coffee, pepper, &c.

6124. *Solution.*—In many operations it is necessary first to dissolve some of the substances. Every one knows that salt will dissolve in water, but that sand or flint will not; this may give an idea of the distinction between *soluble* and *insoluble* substances; but every substance, though insoluble in water, is soluble in something else; and that something is called its *solvent* or *menstruum.* Thus, limestone will not dissolve in water, but it will in strong acid, like oil of vitriol; likewise all the metals are insoluble in water, but they are all soluble in some acid or other: thus, oil of vitriol will dissolve copper easily, but lead scarcely at all, except it be heated. Resins are not soluble in water, but they are so in spirits of wine. Salt is soluble in cold water as well as in hot; but water can dissolve only a certain quantity of it, and then the solution is said to be *saturated.* Hot water dissolves more of some salts than cold, and when the hot water cools, it lets fall all the salt above the quantity that it could hold in solution when cold. On the contrary, water will dissolve sugar without any limit, until it becomes a sirup.

Solutions are said to be *concentrated* or *inspissated* when some of the water is driven from the solution by evaporation. This process, with most animal and vegetable matters, is best performed in a water-bath, to prevent burning, as in the case of portable soup.

6125. *Infusions* are made by pouring water, either boiling, merely warm, or even cold, upon vegetable substances, and letting it stand for some time, without farther boiling. It is evident that the water here can only extract such matters as are soluble in that fluid. The ordinary beverage called tea is an infusion of tea leaves.

6126. *Maceration* differs from infusion, in being continued for a longer time, and can only be employed for substances which do not easily ferment or spoil.

6127. *Digestion,* on the other hand, differs from maceration and infusion, in the water or other menstruum being kept in a state of *continued heat* over a fire, but gentle, and *not* boiling.

6128 *A decoction* is the extraction by water of certain principles in vegetables, by subjecting them to boiling for some time. Many parts of vegetables are not soluble in water, as the resinous substances; but others, as mucilage, are entirely soluble in that fluid. Decoctions, from the nature of their constituents, very soon ferment and spoil; consequently they should be prepared in small quantities only as they are wanted, and never used, particularly in summer, forty-eight hours after they have been made. The well-known beverage, barley water, is a decoction of barley.

6129. *Coagulation* is a thickening of a substance that has been fluid, as the formation of curd from milk when rennet is boiled with it.

6130. *An extract* consists in dissolving by water, spirit, or any other menstruum, such parts of vegetables as are soluble, and afterward inspissating this by heat.

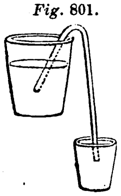
6131. *A tincture* is a solution of any coloured substance in spirit of wine; when not coloured, the solution is called a *spirit*.

6132. *Precipitation* is the reverse of solution. It is the falling down in a solid or powdery state something that had been dissolved, in consequence of the addition of some other body to the solution. Thus, iron may be oxydized and dissolved by diluted sulphuric acid, and the solution will be transparent; but if an alkali be added, the oxyde of the iron will fall down, or be precipitated, in form of a greenish powder.

6133. *A sediment*, on the contrary, is the falling down of a substance that had been *merely mixed* with water or other fluid, but not dissolved, and all that is necessary to produce it is rest for some time. Thus, water may be muddy, that is, contain various matters in a state of mechanical suspension, not chemical solution; but if that water be suffered to rest long enough, all these matters will subside to the bottom as a sediment, leaving the water clear. Substances actually dissolved never subside by standing any time; thus, flour mixed with water will subside; sugar or salt dissolved in it never.

6134. *Decantation*, or to *decant* a fluid, is to pour off gently the supernatant fluid from the sediment without disturbing it.

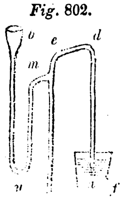
Fig. 801.



6135. *A siphon*, *fig.* 801, is often useful for decanting where there is danger of disturbing the sediment. The siphon may be first filled with the fluid to be decanted, by taking out some carefully with a spoon; then, with the long end of the siphon closed with a cork, plunge the short end into the liquid, and keep the finger upon the opening of the siphon till it is fairly below the surface; now withdraw the finger, and open the long end, and the siphon will run.

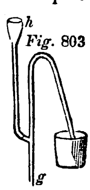
6136. *A small glass siphon*, *fig.* 801, which is easily made out of a piece of tube, is sometimes used for decanting very minute quantities of a fluid; and having stopped the end with the finger, the mouth may be applied to the arm, *h*, to draw the fluid over the turn of the tube; when it has passed that, the fluid will continue to run.

Fig. 802.



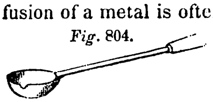
6137. In the siphon invented by M. Collardeau, *fig.* 802, it is not necessary to apply the mouth, nor even the finger, to either end of the tube, a circumstance that may be important when the liquor to be transferred is of a corrosive nature, or otherwise improper to touch with the finger. Dip the end *a* into the fluid to be transferred, and pour into the funnel side opening, *b*, a quantity of the same fluid, until it flows out of the end *c*. The fluid in the vessel then rises, and continues through *a*, *d*, *e*, *c*. In this case the branch *m n* remains full, while the liquid in *b n* subsides to near the bend *n*. The same object is effected by the more simple form of *g*, *fig.* 803, provided the opening of the longer leg is closed with the finger until that branch is full; or the application of the finger is unnecessary if the fluid be poured into the funnel faster than it can be discharged through *g*; in that case the long branch of the siphon will fill, and then act in the usual way.

Fig. 803



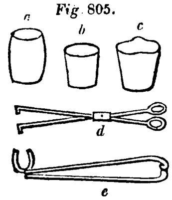
6138. *Fusion* is the conversion of a solid into a liquid by the application of heat. The fusion of a metal is often called *melting*; but, in common language, the term melting is often, also, applied to the solution of a solid in water; thus, we say, sugar *melts* in water; *dissolves* in water would be better. *Liquefaction* means the same thing. The fusion of metals is conveniently effected by an iron ladle, *fig.* 804.

Fig. 804.



6139. *Crucibles* are little vessels, *a*, *b*, *c*, *fig.* 805, for putting certain substances into that are to be exposed to a violent heat of a fire or a furnace. Common ones are made of a particular kind of earthen-ware that resists heat. Some larger ones are made of black-lead. They must be put in and taken out of the fire with a small pair of crucible tongs, *d*, *e*, and they should have covers to protect the substances from the fuel. The bowl of a tobacco pipe makes a very good small crucible.

Fig. 805.



The heat of a furnace will probably be very seldom required in domestic economy; if it should, small portable furnaces may be procured at the dealers in chemical apparatus. Some are made to stand upon a stool, by putting a few loose bricks beneath; but great care must be taken in their use to prevent accidents from the fire.

6140. *The process called washing* is employed for separating powders that are not soluble in water into various degrees of fineness, with greater delicacy than can be effected by any sifting. The substance, after being ground to a fine powder, is mixed with a good deal of water, and agitated; the coarsest and heaviest portion of the powder will settle to the bottom, while the smaller and lighter particles will remain some time suspended in the water. But before they have time to subside, the water is poured off with them into another vessel, and then they are suffered to subside. If it be required to separate a third degree still finer, the water must be poured off again before the whole falls down, and the sediment of this water will give the finest powder. In this manner, every powder may be separated into the various degrees of fineness which are required.

6141. *Lixiviation* is the washing a soluble substance from an insoluble one; as, for instance, to produce the potash from wood ashes. The whole substance is mixed with water, and suffered to stand some time, till the water has dissolved all the salt. The water is then decanted, or filtered off; if this water be evaporated, the salt will be left behind.

6142. *Filtration* is the depriving liquids of some solid particles that are mixed with them. It is to be observed that, if substances are actually dissolved in a liquid, no filtration can separate them: thus, salt can never be separated from water by any kind of filtration whatever, although some persons erroneously suppose it can. Filtration can only separate what is mechanically suspended, and what would mostly fall down of itself by subsidence.

Fig. 806.

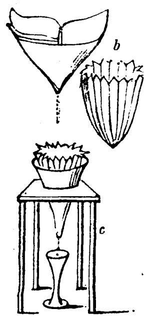


Fig. 807.

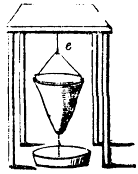
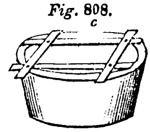


6143. Filters for delicate purposes are made of white unsized paper, and they are folded up so as to make a cone, as in the wood-cut *a*, or as *b*, *fig*. 806; to support this, the paper so folded is put into a funnel, and this funnel into a filtering-stand, *c*. These filters can only serve once.

When large quantities are to be filtered, filtering-bags are used, consisting of a piece of flannel or linen fastened to a hoop, *e*, *fig*. 807; what passes the first time is sometimes not fine enough, and requires being refiltered. Where no great nicety is required, it is sufficient to have a frame, as at *c*, *fig*. 808, and to throw over it a cloth. In filtering thick, adhesive substances, such as sirup, it is sometimes necessary to moisten the filter with water. In filtering very small quantities, the paper cone may be simply put into a glass.

Fig. 808.



6144. *Strainers* are for the same use as filters, and are only coarse filters. They are made of cloths, of metal, or earthen-ware pierced with holes, or wire cloth. Flannel is often used.

6145. *A tamis* is a worsted cloth, sold at the oil shops, made on purpose for straining sauces: the best way of using it (says Dr. Kitchener) is for two people to twist it in contrary ways; this is a better way of straining sauce than through a sieve, and refines it much more completely.

6146. *The operation of sifting* is well known. It is employed for separating certain substances from others, or for mixing together powders very completely; and likewise for procuring particles as nearly as possible of equal sizes, whether coase or fine. Sieves are made of wire cloth, hair cloths, or of open lawn or muslin. Pierced zinc is also used; and in some countries where persons are obliged to make their own sieves, parchment strained over a frame, and pierced with numerous holes with a hot iron wire, answers tolerably well.

6147. *Clarification* is the process of clearing and fining any fluid from all impurities or feculence. It is performed either by heat, or by the addition of some substance which will unite with and precipitate or raise to the surface the matter which makes the liquor turbid. The substances usually employed are the white of eggs, blood, and isinglass. The first two are generally used for such liquors as are clarified when hot, since the albumen of the egg, or of the blood, when beaten up with a portion of the fluid, coagulates by the heat, and, rising to the surface, carries with it the impure matter in the form of a scum. Isinglass dissolves in the liquid, and sometimes rises with the impurities as a scum, but sometimes falls down to the bottom, as in the case of wine.

6148. *To express* is to separate fluids from solids by mechanical pressure, and is used chiefly for obtaining the juice and oils of vegetables. It is performed by a lever or screw press. The substances are enclosed in a bag of cloth, introduced between the plates of the press. Hair cloth is the best for the bags, as it does not impart any peculiar taste. To some vegetables that are not juicy enough, the addition of a little water is necessary. For unctuous seeds, heated iron plates are sometimes used; when the iron is cold, the oil is styled *cold-drawn*.

6149. *Evaporating*, or *vaporization*, is the conversion of a liquid into the state of vapour, as water into steam. No body in nature can be destroyed; and what is commonly called the drying up of water is but its conversion into vapour, which is either dissolved in the atmosphere, or rendered visible as steam. Water, when exposed to the air, is constantly evaporating, but heat accelerates this process; consequently, when we wish to evaporate water quickly, we employ heat. The larger the surface of the water, the more rapid will be the evaporation, and therefore we put it into large shallow vessels. It is to be observed that the atmosphere is not a necessary agent in evaporation, but rather, by its pressure, it tends to prevent it; for, if we take off the pressure of the air by removing it altogether from the evaporating surface by exhausting, the evaporation will go on much faster; an instance of which was mentioned in an improvement in the manufacture of sugar; and the same principle is applied in procuring the extract of vegetables. Shallow pans, or basins, are made for evaporating in, of which those of a kind of porcelain, called Wedgewood's, are the best when heat is used.

6150. *Decomposition* is the complete separation from each other of the elementary principles of which compound bodies consist; by decomposition all the properties of such a substance are destroyed.

6151. *Effervescence* is the bubbling occasioned by the escape of gas from any liquid, giving an appearance like boiling. An example of this is seen when muriatic acid is poured upon chalk.

6152. *Funnels* are made of tinned iron, pewter, stone-ware, white or brown, glass, and of various sizes. Very small funnels are useful to fill vials and other small bottles. Where acids are to be poured, glass or earthen-ware are requisite, as metal will be corroded. Glass is excellent, because one can see if it be perfectly clean.

6153. *Test Papers for detecting Acids and Alkalies.*—These are sold at the chemists'. That for ascertaining whether any acid exists in a liquid is blue; if there is any acid, the blue paper, tinged with litmus, will turn red when dipped into it. Those for alkalies are yellow, with turmeric; any alkali in a liquid state will turn them brown.

6154. *The ground stoppers of vials sometimes get so fixed* that they can scarcely be moved. Several methods have been practised for loosening them. When the hand is not strong enough, a hand-vice may be tried; but great care must be taken that it does not break the vial. Tapping each side of the neck successively with a piece of hard wood sometimes produces the desired effect. When these methods fail, heat may be tried. Plunge the neck of the vial into boiling water, or heat it gently by a spirit lamp. Here care must be taken that the contents are not very volatile, or they may burst the bottle. When the neck has been warmed, which expands it, a smart blow with the hand, struck upon the bottom of the bottle, sometimes detaches the stopper A little olive oil put round the stopper for a day or two, will soak into the neck and often loosen the stopper When all these methods fail, the stopper, if it be worth the expense, as in the case of a decanter, may be got out by sending it to the china-mender, who works it out by a drill.

6155. *With respect to quantities in the preparations of the still-room or kitchen*, it is very important to have a certain precision, and in some cases it is absolutely essential. Instead of the frequent ill-defined directions of a bit of this, a handful of that, &c., Dr. Kitchener particularly recommends that cooks should accustom themselves to use weights and measures more frequently. There should be a measure for a gallon, a quart, a pint, and half a pint. Graduated glass measures are sold at the chemists', which save much trouble, *fig.* 809. One of these, containing a wine pint, is divided into sixteen ounces, and the ounce into eight drachms of water, by which a certain weight, which is mentioned in a receipt, can be measured out. Measures of this kind are easily made by weighing the water, and scratching a mark on any tall glass for the space it occupies. A file will do to mark with.

Fig. 809.

6156. *A table-spoonful* is often mentioned as a measure or quantity in a recipe or prescription, as given by medical men, or in books. By this is generally meant and understood a measure or bulk equal to what would be produced by half an ounce of water.

6157. By *dessert-spoonful* is meant the half of a spoonful; and a tea-spoonful is in quantity equal to a drachm of water. This is best adjusted by a graduated glass measure, sold at the glass shops, for spoonfuls.

6158. *A drop* is the name of a vague species of measure, so called because the liquid is dropped from the mouth of a bottle; but the quantity of a drop may vary, depending upon the consistency of the liquid, and upon the size and shape of the mouth of the bottle from which it proceeds. The London College of Physicians have fixed the quantity of a drop to one grain, sixty drops being a fluid drachm. This sixtieth part of a fluid drachm they call a *minim:* and glass tubes, graduated for the purpose of measuring minims, may be purchased at the glass shops.

6159. *A good balance or pair of scales* is necessary. It is requisite to have scales for ordinary uses, and others for occasions where greater delicacy is required. Fine scales should be kept in a box secluded from the air, and should never be overloaded. They should be used in a good light.

6160. *Glass rods, or tubes*, are convenient for stirring; so are the stems of tobacco pipes. As glass tubes are liable to be broken by rolling off the table, soften one end in a flame, and bend about an inch; they will not then roll.

6161. *Glass tubes may be bent* and drawn out by the heat of a good spirit lamp, and may be broken at any required place by first making a mark on it with the corner of a file. Larger tubes may be softened and bent over a charcoal fire in a small portable furnace. *Glass blowing*, with a table and bellows on purpose, might afford an elegant and useful amusement, as thermometer bulbs and other useful things are easily made.

6162. *Spoons* of metal and wood are used for various purposes; a *spatula* is for rubbing pastes

6163. *Cements of various kinds* should be kept in the still-room for occasional slight purposes, or for mending furniture. Of the first, *flour paste* is well known: if required to be stronger than usual, a little glue may be boiled in it: some put powdered resin in it. *White of egg*, or a *solution of glue* and *strong gum water*, are good cements. *A paste made of linseed meal* dries very hard and adheres firmly. *A soft cement* is made of yellow wax melted with its weight of turpentine, and a little Venetian red to give it colour. This, when cold, is as hard as soap, but can be softened by the warmth of the hand, and is very useful to stop up cracks, and is better to cover the corks of bottles sent to a distance than sealing-wax or hard cement. *Plaster of Paris* may serve as an occasional cement.

6164. *Other fittings-up in the still-room* should be the following:

A small sink with water laid on, which may be covered over when not wanted; towels, brushes, and other apparatus for keeping everything perfectly clean, should be always at hand. *Cupboards* for keeping things out of the dust; and shelves along the walls to keep things on that are wanted often. On no account should any bottle or vial be suffered to remain without a carefully-made and accurate label, as numerous accidents have happened through neglect of this caution. *A strong table*, and two or three small ones, as well as stands; *a nest of drawers*, to keep small articles and materials; *a grate*, with a boiler on one side and an oven on the other, is necessary; the latter will often be useful for drying things. Hobs of the grate should have a sort of canopy, to prevent dust from falling upon whatever is placed upon them.

6165. *For fuel, in the operations of the still-room*, besides coal, coke and charcoal are wanted. Coke has the advantage of giving a great heat without any smoke; the Staffordshire coke is the best, though dearest. Anthracite, likewise, gives no smoke. Charcoal is the best fuel for many nice operations. Boxes with fuel should be kept in the room: they may be on rollers to slide into recesses. See Section "On Fuel."

6166. *The walls of the still-room should be whitewashed* and painted of a light straw colour, both for the sake of having the most light, and that it may be easily renewed and kept perfectly clean.

CHAPTER III.

DESCRIPTION OF ESSENTIAL OILS, OR ESSENCES, AND THE MODE OF PREPARING THEM.

6167. We here beg to remind our readers of what has been stated in a previous part of this work, that vegetables yield two distinct kinds of oil; one called *fixed*, or *fat oils*, because they do not rise, nor are volatilized, except at such temperatures as are sufficient to decompose them; such is olive oil. These are also termed *expressed oils*, because they are obtained by employing strong pressure. The other kind of oil is called *volatile oil*, because it rises by vapour at a gentle heat, and is easily obtained by distillation: these are also sometimes termed *distilled oils* and *essential oils*.

6168. *The essence of a vegetable* is a term that was given by the old chemists to that principle in which resided the taste and odour, as well as the pungency, which peculiarly distinguished it from other vegetables. Thus, the fragrance of orange or lemon peel, of peppermint, or of cinnamon, and the pungency of cloves, were found by experience to be separable from the other parts of the vegetable by means of distillation, &c.; and the result of this was a small portion of a highly aromatic and odoriferous oil, in which was contained the entire odour that had been dispersed through the whole mass; hence the oils thus procured obtained the name of *essences*.

6169. *These essences, or essential oils, most of which are highly odorous*, furnish the most valuable materials to the perfumer (See "Perfumery," Book XIX., Chap. IX.), are employed in spirituous liquors used at the table, and in cookery, and likewise in medicine, painting, &c. They exist in various parts of plants: in some, as thyme, the oil is contained in all parts of the plant; in others it is contained only in the leaves, the fruits, the seeds, the flowers, the roots, or the bark. In some cases, different parts of the same plant contain different oils: the orange, for example, has three different oils; one in the leaves, another in the flowers, and a third in the fruit. The quantity of oil varies not only with the species of plant, but with the soil and culture, and particularly with the climate; thus, in hot climates, plants yield most essential oil. In some plants the oil does not escape in drying; others lose it immediately, particularly flowers.

6170. The essential oils are chiefly obtained by distillation: a few are obtained by expression, as those of the orange, lemon, and bergamot. To extract the odorous oils of certain flowers, as jessamin or tuberose, infusion in a fat oil is sufficient. These are called, also, volatile oils.

Their taste is exceedingly hot and pungent, and in some, particularly the oil of peppermint, followed by a remarkable sensation of coldness, though the thermometrical temperature undergoes no change. The acrimony of some of the oils, as the oil of cloves, is so great as actually to destroy the outer skin of the tongue, and of other sensible parts. They have not always the same tastes with the plants they are distilled from, or, at least, not in the same degree. Nothing is more bitter than wormwood; yet the oil of wormwood has no remarkable bitterness. Anise, which is of a sweet taste, yields, on the contrary, an oil infinitely more sweet than the seed; and pepper, which is so remarkably hot and acrid, affords an oil no way remarkable for its pungency. Thyme, which is in itself very acrid and pungent, conveys that property in a yet greater degree to its oil; there is, indeed, no essential oil so acrid and fiery as that of this plant.

The number of these oils is so great as to baffle all enumeration, almost every odoriferous plant being distinguished by a peculiar oil, to which it is indebted for its perfume.

6171. *The following table* exhibits the most prominent properties of most of the essential or volatile oils :

Name.	Colour.	Specific Gravity.	Consistency at 60°.	Odour.	Procured from
Rosemary	none	·934	thin liquid	like the plant	Ros marinus officinalis.
Fennel	—	·997	becomes solid at 50°	—	seeds of Anethum fœniculum.
Sassafras	none	1·094	oily	like the root	root of Laurus Sassafras.
Tansy	—	·946	—	very strong	leaves of Tanacetum vulgare.
Caraway	none	·946	—	very strong and pungent	seeds of the Carum carri.
Pennyroyal	—	·978	—	like the plant	flowers of the Mentha pugilium.
Anise seed	none	—	becomes solid at 50°	very strong	seeds of Pimpinella anisum.
Thyme	brown	—	crystallized	like camphor	leaves and flowers of Thymus serpillum.
Lavender	none	—	thin liquid	like the plant	flowers of Lavendula spica.
Wormwood	green	—	—	—	leaves of Artemisia absynthium.
Chamomile	blue	—	—	—	flowers of Arthemus nobilis.
Hops	green	—	like butter	like the flower	
Parsley	green	—	—	—	flowers of Humerus lupulus.
Peppermint	green	—	thin liquid	like the plant	leaves of Apium Petroselinum.
Savin	none	—	—	disagreeable	leaves of Mentha piperitis.
Coriander	—	—	—	—	seeds of Coriandrum sativum.
Saffron	—	—	—	—	pistils of Crocus sativus.
Turpentine	none	·742	fluid as water	strong	resin of Pinus sylvestris.
Juniper	green	·611	very fluid	strong smell	seeds of Juniperis communis.
Cloves	none	1·034	oily, very fluid	like cloves	capsules of Eugenia caryophillata.
Lemon	yellow	—	thin liquid	like the fruit	rind of the fruit of Citrus medica.
Orange	yellow	·888	ditto	ditto	rind of the fruit of Citrus aurantium.
Neroli	yellow	·800	ditto	ditto	flowers of ditto.
Cinnamon	yellow	1·035	oily and liquid	like cinnamon	bark of the Laurus cinnamomium.
Nutmegs	none	·948	like butter	like nutmegs	seeds of Myristica moschata.
Bergamot	yellow	—	not oily ; solid at 23°	like oranges	rind of the fruit of Citrus aurantium.
Mace	—	—	oily	—	seeds of Myristica moschata.
Roses	none	—	like the flower	—	petals of Rosa antifolia.
Pepper	none	—	like butter	very acrid	seeds of Piper nigrum.

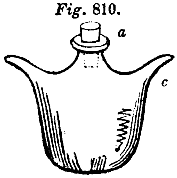
6172. Essential oils are not obtained from odoriferous substances in quantities proportioned to their degree of odour. Some which, if we were to reason from analogy, should seem very well fitted for this process, yield extremely little oil, and others none at all. Roses and chamomile flowers, whose strong and lasting smell promise abundance, are found to contain but a small quantity of oil ; the violet and the jessamin flowers, which perfume the air with their odour, lose their smell upon the gentlest coction, and do not afford any oil on being distilled, unless immense quantities are subjected to the operation at once ; while savin, whose disagreeable scent extends to no great distance, gives out the largest proportion of volatile oil of almost any vegetable known.

6173. As examples of the quantities of essential oils yielded by different plants, the following may be mentioned : 6 oz. of the *oil of juniper* may be procured from 48 lbs. of the berries ; 1 lb. 9 oz. of the *oil of lavender* may be obtained from 80 lbs. of lavender flowers ; 1 oz. of *oil of rosemary* may be had from 24 lbs. of the plant.

6174. *Obtaining the essential oils themselves from the several productions* is seldom attempted in domestic practice, as they may be purchased ready prepared from a respectable chemist or apothecary : when they are procured by distillation, the processes are the same as those which we shall describe for obtaining the distilled waters, with the exception that less water is employed, and, of course, a much larger quantity of the leaves, flowers, or other parts of the plants. Many of them are made in those warm climates where the plants grow in greater abundance than with us. The chief manufacture of the essential oils or essences which we have is in the south of France; as those of rose, neroli, lavender, thyme, lemon thyme, and rosemary. Some of them, as the oil of lavender and fennel, are made of the best quality in this country : the English oil of lavender is three times as dear, and very much superior to the French.

6175. *We cannot separate the volatile oils from the aromatic plants by distilling them alone,* because the proportion of these oils is so small that they could not be collected ; and, besides, it would be impossible to regulate the heat so as to be sufficient, and yet not burn the materials, and destroy the product. Hence it is necessary to distil them with a proportion of water. During the process of distillation, the volatile oil rises with the watery vapour, and condenses with it in the receiver, where it is partly dissolved by the water. The greater part, however, of the oil again separates from the water, after it has remained at rest for some hours in a cool place, and either floats on the surface, or sinks to the bottom, according as it is lighter or heavier than its bulk of water.

Fig. 810.



The essential oil thus procured can be completely detached from the water by an instrument called a *Separatory.*

The fluids to be separated are introduced through the orifice *a*, *fig.* 810, which is then closed with a stopper. One neck is then shut with the finger, and the vial is to be inclined to the other side. As soon as the fluids have separated by means of their specific gravity, the finger is to be removed, and the whole of the heavier fluid will run through the lower neck before any of the lighter escapes. Another method of effecting the same thing is to put the whole into large narrow-necked bottles, setting them in a cool place, that the portion of the oil which is not dissolved in the water may rise to the top, or sink to the bottom. It may then be separated, either by a small glass syringe, or by means of a filter of paper; or, lastly, by means of a woollen thread, one end of which is immersed in the oil, and the other, the lower end, in a vial; the oil will thus pass over into the vial by capillary attraction; and the thread is to be squeezed dry.

6176. In proceeding to procure a greater quantity of the oil with fresh leaves or flowers, the whole of the water produced by the first distillation is employed in the next, instead of plain water, so that thus the produce of oil in the second distillation will exceed that of the first by the whole quantity held in permanent solution by the water of the former process. By this method the amount of oil yielded by equal quantities of the same substance will form a constantly increasing series, till the whole of the water drawn off by each distillation is completely saturated with oil. It is not till the seventh, or even sometimes the tenth distillation, that the produce of oil attains its maximum. Tall alembics are the best for these distillations. It is to be observed that, if too much water be used, the oil will dissolve in it, and only an aromatic water will be procured; if too little water, the plants may be charred.

6177. *In this manner the essence of roses* is procured: Put into the body of the still 40 pounds of rose petals and 60 quarts of water; distil off one half of the water. When a considerable quantity of such water of the first distillation is obtained, it must be used as water upon fresh rose petals; a process of repetition to be carried to the fifth time. In the distillation of orange flowers, to obtain the essence of neroli, the same process is followed. If orange-flower water merely be wanted, then it is obtained at one distillation, by reserving the first fifth part of water that comes over.

6178. *The celebrated attar of roses*, a precious perfume, which is the essential oil of roses, is prepared in Persia and India. Ghazipoor, on the Ganges, seventy miles below Benares, is famous for its manufacture of this costly perfume; hundreds of acres are there employed in the cultivation of roses, and it is said that it requires 200,000 roses to produce half an ounce of the attar. To procure it, a clean cask, or glazed earthen jar, is filled with petals of the musk rose separated from their calyces, and they are then covered with spring water: the vessel containing them is set in the sun for two or three days, and brought under cover in the night. At the end of the third or fourth day small particles of yellow oil float on the surface of the water, which, in a week, accumulates into a thin scum; this scum, which is the attar, is taken up by a little cotton tied to the end of a stick, and squeezed into a small vial. It sells for from £2 to £3 per ounce. The Persian attar of roses is said to be superior to the East Indian.

6179. *The essences of the lemon, the orange, and the bergamot* are the only ones that are so abundant as to be obtainable by *expression*. For this purpose, a small wheel, with its circumference set with stout nails, is put in motion, and a lemon or orange is applied to it till the whole of the yellow outer rind is rasped away. The raspings fall to the bottom of the case in which the wheel turns, and they are then squeezed between two plates of glass. By this gentle pressure the oil flows from the ruptured cells into an adjoining vessel, and is there suffered to rest till the water and the other impurities have subsided. This essential oil is soluble in all proportions in pure alcohol; but only 14 parts dissolve in spirits of wine.

6180. *A very ingenious mode is employed for fixing the aroma, or perfumes, of plants in expressed oils* without the assistance of any but the gentlest heat. The oil which is used is either oil of behn or the purest olive oil, both of which are entirely scentless. The flowers whose aroma is to be extracted, jessamin flowers for example, are thickly spread upon flakes of wool, previously soaked in the oil; then they are enclosed in tin boxes, and suffered to remain till the flowers begin to decay, and lose their colour and texture. They are then removed, fresh flowers are added, and the maceration repeated till the oil becomes richly impregnated with the jessamin scent. This oil is then put into a still with water, and the essential oil comes over with the water; or the wool is pressed, and the fragrant oil separated from the flowers is put into closely-stopped bottles, and sold under the name of *essence* of jessamin. These essences, therefore, consist of a fixed oil saturated with the aroma of the plant.

CHAPTER IV.

SIMPLE DISTILLED WATERS, AND METHOD OF PREPARING THEM.

6181. When any vegetable matter is boiled with water in a vessel fitted to collect and condense the vapour, the distilled water so obtained is, in almost every instance, somewhat impregnated more or less with odorous or sapid particles, which it has extracted from the vegetable, and carried up with it in the process. But the difference in the degree of impregnation, according to the substance employed, is extreme. Sometimes only a faint and nauseous taste is given, which soon goes off; but in other instances the water is highly scented, and has much taste. The first occurs where the plant is of the herbaceous and nearly insipid kind, or only bitter without being aromatic; but where the plant is rich in essential oil, or strongly aromatic, the water partakes largely of these properties. What are called distilled waters, therefore, consist of simple water slightly impregnated with the essential oils of different plants. A great variety of these have been used formerly, most of them obtained from the vegetable kingdom; and many were procured from the inodorous herbaceous plants for purposes of pharmacy. In France they enumerated no less than 125 different distilled waters, one half of which have scarcely any flavour or virtue. The greater part are now disused in this country, being considered of no value; and a very few only are retained.

6182. *The distilled waters made in Britain* are prepared from the *aromatic vegetables*, from most of which an *essential oil* may also be obtained; and as the water distilled from them tastes and smells strongly of the oil peculiar to the plant, and also as a water very similar to that which is distilled may generally be made by dissolving some of the oil itself in plain water, there can be no doubt but that the distilled waters of the aromatic vegetables owe their strong smell and taste to the essential oil which they hold in solution. It has, indeed, been suggested that the principle which occasions the odour may be in some cases distinct from the essential oil itself; but as these have never been separated, and as their distinction is a point which chemistry has not yet determined, it is sufficient for us here to adopt the prevailing opinion.

6183. *The process for preparing these simple aromatic distilled waters* is as follows: The herbaceous or dried plants should first be thoroughly macerated in water, to open their texture, and make them yield their essential oil more abundantly. When herbaceous plants are used, such as peppermint for example, they become sufficiently macerated in the time that it takes to bring the water to a boiling heat, so that no previous preparation is necessary, it being sufficient to put them into the still with the requisite quantity of cold water. But the woods and other hard parts of plants should be macerated for some time before distillation, being previously well bruised, and their texture broken down. If a glass alembic is used, it should be placed on a sand-bath; if a copper or tin one, it should be put into a water-bath. The quantity of water required must vary, of course, according to the nature of the substance used. Herbaceous plants recently gathered require that the still, or alembic, should be filled only to two thirds of its capacity, with the plants moderately pressed, and so much water added as will fully cover them: if too many plants are put in, as they swell much, they would choke up the head of the still. The fire should be raised expeditiously at first, as a long-continued heat is apt to impair the aromatic flavour. The first drops that come over are insipid, and should be thrown away: soon the water which comes is milky and turbid, owing to an excess of essential oil, which it carries up with it above the quantity which it can hold in clear solution; this excess of oil, when the distilled water cools gradually, collects at top in form of a thin film, or subsides to the bottom according to its specific gravity. As the water distils over it becomes clearer, and proportionally less aromatic to the taste; till at last, when perfectly limpid, it appears nearly insipid, and the fire should then be withdrawn. Much care is necessary to prevent any of the vegetable matter from being scorched during the process, and the distillation should be stopped before any burned or empyreumatic flavour is perceived.

6184. *Another method of procuring distilled waters is sometimes employed* by what is called the *cold* still, and which has been much practised in private families. A shallow leaden vessel is filled with fresh herbs, flowers, &c., which are heaped above it; so that, when the head is fitted on, this also may be filled a considerable way. A little fire is made under the vessel, sufficient to make the bottom much hotter than the hand can bear, care being only taken not to heat it so far as to endanger the scorching any part of the plants. If the bottom of the vessel be not made so hot as to have this effect on the part contiguous to it, there is no fear that the heat communicated to the rest of the included materials will be so great as to do them any injury. By this management the volatile parts of several odorous plants, as mint, are effectually forced over with the moisture, and if the process has been skilfully managed, the distilled liquor which collects in drops in the glass receiver proves richly impregnated with the native odour and flavour of the plants, though it will be small in quantity.

6185. *Still another mode has been used*, which is more expeditious and certain. A quantity of water being poured into the still, and the herbs, or flowers, placed in a basket over it, there can be no possibility of burning. The water may be made to boil, but so as not to rise up into the basket. The steam, only passing gently through the leaves, imbibes and carries over it the volatile parts unaltered. In the common still, the vapour rising upward before it is condensed, the distillation is said by chemists to be *per ascensum;* but there is another mode of distillation, *per descensum*, in which the vapour descends to be condensed. A cylinder of copper, tinned inside, may be cased in wood; the leaves may be stuffed into this, and steam forced down through them.

6186. *When an alembic, or still, is not at hand, a small quantity of simple distilled waters may be procured* by the following method: Put a small quantity of water into a glazed earthen jar, and tie a piece of open muslin or gauze over the mouth, leaving it to hang down inside a little loose: place the flowers on the muslin, and having put some lighted charcoal into any metal vessel, such as a warming-pan, place the bottom of it (just hot enough not to burn or scorch) so as to fit tight to the mouth of the jar containing the leaves. By the heat the essential oil of the flowers will be forced out, and not being able to ascend, will descend into the water, which will be richly impregnated.

6187. *The degree of the impregnation of the water*, or the quantity of water which a plant is capable of saturating, is by no means in proportion to the quantity of its oil. The oil saturates only the water that comes over at the same time with it; if there be more oil than is sufficient for this saturation, the surplus separates, and concretes in its proper form, not miscible with that which rises afterward. Some odoriferous flowers, whose oil is in so small a quantity that scarcely any visible mark of it appears, unless fifty or one hundred pounds or more are distilled at once, give, nevertheless, as strong an impregnation to water as those plants which abound most with oil.

6188. *Most distilled waters, when first prepared,* have a somewhat unpleasant smell, which, however, they gradually lose; it is therefore advisable to keep them for some days after their preparation in vessels but slightly covered, and not to cork them up until they lose that smell. After some months they frequently spoil; but to make them keep better, one twentieth of their weight of proof spirit may be added. If they be rectified by distilling a second time, they will keep for several years without the addition of any spirit, which always gives an unpleasant flavour, and is often objectionable for other reasons.

6189. *The distilled waters, as commonly prepared for sale,* are seldom of the best quality; and the housekeeper who wishes to possess them in a state of perfection must distil them under her own inspection, and preserve them with the caution that will be directed. In the country, where there is generally a gardener, this may likewise be a desirable object of economy, and may afford an amusement neither inelegant nor uninstructive to the several branches of the family.

6190. *To prepare Rose Water.*—When the buds of the red rose begin to expand into the full-blown flower, their perfume is most perfect, and in that state they should be gathered in a dry morning, the heels cut off, and the leaves only put into a clean cask in layers, with salt sprinkled between them, to preserve them till they are collected in quantity sufficient for distillation. Fill the still two thirds with the petals and salt together, with a little water at the bottom to prevent burning, or have the still put into a water-bath; proceed to the distillation with a very slow fire, and receive the first product in several vials, in order to examine it. The first will be highly impregnated; and, as soon as the slightest empyreumatic odour or burned smell is perceived, throw away the portion that is contaminated, and stop the distillation. Rose water should be kept in a cool, dark place, as heat and light speedily cause it to spoil. It is best to put it into a stone jar with a cork, that it may be drawn off without disturbing the sediment, which is apt to be the case if decanted from small bottles. It should be made in small quantities at a time, as it will not keep long: the salted leaves will keep for months, and do as well for distillation as when fresh gathered; but it is to be observed that it is an error to suppose that the salt is of any farther use in the distillation than to keep the leaves from spoiling.

6191. *Perfumed tepid water* for the finger glasses before the dessert may be easily prepared by infusing a few fresh or dried rose petals, lavender, or any other flower, in the morning for the purpose.

Rose water is said to have been first made in Persia; and the Persian rose water was long esteemed as the best. Our roses give but little perfume.

6192. *Distilled waters may be prepared in a similar manner from any of the fragrant herbs or flowers.* The fragrance of lavender and jessamin, with many others, when distilled very slowly with a weak spirit, are readily extracted.

6193. *Orange-flower water,* which is in the highest request, cannot be made from the flowers in this country; it is chiefly imported from France and Italy; the best is from Leghorn. Orange flowers are collected every morning in May and June for thirty miles round Paris from both public and private gardens, and, likewise, the buds that fall from the trees, to make this perfume. When this water is obtained by distillation from the fresh flowers, it contains a peculiar principle, in consequence of which the water becomes red by a few drops of sulphuric acid; and the intensity of the rose colour is, in some measure, a test of the richness of the water in essential oil. Orange-flower water may be made by dissolving a little of the oil of orange flowers, called *neroli,* in water. What is imported may be improved by putting into a jar containing from fifteen to twenty gallons, two or three lumps of white sugar, having dropped upon them about forty drops of bergamot.

What is called essence of *petit-grain* is obtained by distilling the leaves of the orange shrub.

The only distilled waters retained at present by the London and Edinburgh Colleges for the purposes of medicine are those prepared from orange peel, sweet fennel, rose leaves, peppermint, pennyroyal, spearmint, lemon peel, cinnamon, cassia cinnamon, dill seeds, and pimento.

6194. The following directions for preparing distilled waters used as medicines are from those in the dispensatories:

Distilled Water.—Take of water ten gallons. Distil four pints, which are to be rejected; then distil four gallons, to be used. The first and last portions of the water are rejected as impure.

Peppermint Water.—Put a pound and a half of the peppermint into the still. Pour over it as much water as will prevent empyreuma, or burning, during distillation. Distil a gallon.

Pennyroyal Water.—The process is the same as the last. Distil as long as the water has the fine flavour of the herb.

Spearmint water is procured in the same manner.

Cinnamon Water.—Steep one pound of bruised cinnamon in a gallon and a half of water for two days; then distil off the water till it ceases to run milky; put what comes over into the still, and distil again.

Water of Orange Peel.—Take of fresh orange peel two pounds; add so much water that when ten pounds have been drawn off by distillation there shall remain a sufficient quantity to prevent empyreuma. After due maceration distil ten pounds, to which add five pounds of diluted alcohol.

CHAPTER V.

MODE OF PREPARING SPIRITUOUS AROMATIC DISTILLED WATERS, AND SPIRITS OF THE PERFUMERS.

6195. There is some ambiguity and confusion in the names usually given to these preparations, but they will be easily understood from the following explanation. We stated that the vapour of water and the essential oils rise together in distillation, and form the simple distilled waters, but that water would only take up a certain portion of the essential oils, the remainder separating from it on cooling; water is therefore only slightly impregnated with the essential oils of vegetables. Spirit of wine has this advantage over water, that it keeps all the essential oil in a state of solution, and can therefore be much more highly impregnated with the odours and other properties of the oils. Nevertheless, as spirit of wine is extremely volatile, it is sometimes more so than the essential oils, and therefore it will rise first, and, consequently, without the oils; whereas water, requiring more heat to be converted into vapour, will not rise until the essential oil does the same. Thus, if cinnamon, for instance, be committed to distillation with a mixture of spirit of wine and water, or with a pure proof spirit, which is no other than a mixture of equal parts of the two, the spirit will rise first, clear and transparent, and almost without any taste of the cinnamon; but, as soon as the watery part begins to rise, the oil comes over freely with it, so as to render the liquid highly odorous and sapid. The proof spirits commonly sold have a certain disagreeable flavour, owing to the essential oil of the barley from which it is made, which, though in general concealed, in a great measure, by certain additions, plainly discovers itself on distillation; but this nauseous smell is not perceived until after the purer spirituous part has come over, which is the very time when some of the essential oils also begin to distil. On this account it is of great importance to have very pure spirit for the purpose of procuring spirituous waters.

6196. What are called *spirituous waters* are where only proof spirit, that is, half pure spirit and half water, has been employed.

An example of a spirituous water may be given in the case of orange-peel water, the receipt for the simple distilled water of which has already been given.

6197. *Spirituous Orange-peel Water.*—Take of the outer rind of Seville orange peel, dried, half a pound; proof spirit, one gallon; water, as much as is sufficient to prevent empyreuma. Distil off one gallon. This is considerably stronger than the simple orange-peel water. It is used as a cordial and stomachic.

6198. *Spirituous Jessamin Water.*—Take of Spanish jessamin flowers twelve ounces; essence of Florentine citron or bergamot, eight drops; fine proof spirit, one gallon; water, two quarts. Digest for two days in a close vessel; after which draw off one gallon, and add sugar.

6199. *Spirituous Peppermint Water.*—Take of peppermint leaves, dry, a pound and a half; proof spirit, one gallon; water, as much as is sufficient to prevent empyreuma. Distil off one gallon. This smells and tastes very strongly of peppermint, and is used medicinally.

6200. *What perfumers term spirits of certain plants*, as spirits of lavender, *consist of* the essential oil of the plants dissolved in proof spirit, by putting the plants, with alcohol, into a still, and drawing off the scented spirit; or they are obtained by digesting the odoriferous substances with spirit in a sand heat.

6201. Formerly the term *spirit* was applied by chemists to all volatile substances collected by distillation, and hence some of the essential or volatile oils were termed spirits. Some of these names are not yet entirely banished; thus, the essential oil of turpentine is still improperly called spirits of turpentine. The term spirit is at present, among perfumers, usually confined to alcoholic solutions. But while some perfumers call these spirits, others name them *essences*, a term which ought to be confined to the pure essential oils.

6202. *Spirituous perfumes are also prepared* by putting the essences procured by means of the fat oils into a distilling vessel with alcohol. The aroma which was joined to the oil leaves it for the spirit, and the fixed oil remains; thus a highly perfumed spirit is procured instead of an oil.

6203. *To avoid the trouble of distilling* with the plants themselves in preparing perfumers' spirits, it is very usual now to mix a small quantity of the essential oils of the several plants with proof spirit. Thus, spirit of roses may be made by adding three drachms of attar of roses to two pints of rectified spirits: spirit of jessamin may be procured by adding half a drachm of the essential oil of jessamin to eight ounces of rectified spirit; but the best method of combining the perfumes with spirits is the following: Into each of three digesters, immersed in water-baths, put twenty-five pounds of any one of the essential aromatic oils, and pour into the first digester twenty-five quarts of spirit of wine; agitate every quarter of an hour during three days, and at the end of this period draw of the perfumed spirit, and pour it into the second digester; then transfer it after three days into the third digester, treating the mixture in the same way; and the spirit thus obtained will be perfect. The digesters must be covered carefully during the process of these operations. On pursuing the same process with the same oil and fresh alcohol, essences of inferior qualities may be obtained. Some perfumers state that it is better to use highly-scented pomades than oils.

6204. *Spirit of Bergamot.*—This fine perfume comes from Italy, and cannot be prepared in perfection in England for want of the fruit from which it is prepared, which is a species of lemon (*Citrus limetta*). The best is from Rome; that from Leghorn is inferior. Directions are given for making an inferior kind, as follows: Mix one gallon of proof spirit of wine and one gallon of water with half an ounce of Roman oil of bergamot beaten in a mortar with fine sugar. Put the whole into a still in a water-bath, and draw off six quarts.

6205. *Spirit of Lavender.*—Infuse six ounces of fresh lavender flowers in one gallon of proof spirits, and digest in a sand heat. Repeat the infusion of fresh flowers four times, and an excellent spirit will be obtained. The flowers should be gathered very dry, stripped from their stalks, and kept in paper bags. Or, put a pound and a half or two pounds of fresh lavender flowers into a still; add one gallon of proof spirit of wine. Distil off one gallon. This, by some perfumers, is called *lavender water*. It is apt to be adulterated with oil of turpentine.

6206. *Spirit of Ambergris.*—Reduce to powder with loaf-sugar 1½ oz. ambergris, 20 grains civet, musk 30 grains. Add the fourth of a green lemon, and digest the whole in 3 pints of rectified spirits of wine.

6207. *Spirit of Musk.*—Reduce to powder with loaf-sugar 1½ oz. musk, 40 grains civet, and ¼ oz. red rose-buds. Digest the whole in 3 pints of spirit of wine; or they may be distilled by an alembic.

6208. *Hungary Water.*—This, though it retains the name of water, is properly a spirit. Take of rosemary flowers, just gathered, two pounds; rectified spirit of wine, three pounds; put them together, and distil in a water-bath. Some add lavender flowers. That which is imported is generally superior to what is made here, which is probably owing to the manufacture. A very pure spirit should be employed. The best method of managing the distillation is to place the spirit in the still, and then place above the liquor either an iron hoop, with a hair cloth stretched over it, upon which the flowers are to be lightly spread, or, rather, a basket, supported on three pins, reaching down to the bottom. A gentle heat being applied, just sufficient to raise the spirit, its vapour, lightly percolating through the flowers, will imbibe their essential oil, which thus is obtained extremely pure.

A simpler Hungary Water by infusion.—Add to a pint of rectified spirit of wine an ounce of oil of rosemary and two drachms of essence of ambergris; shake the bottle well several times, then let the cork remain out for twenty-four hours; shake it each day for a month, and then put it into small bottles well sealed.

6209. *Eau de Cologne,* improperly called a water, as it is a spirit.—The following recipe is given by Dr. Granville for making this celebrated perfumed water equal in quality to that of Farina in Cologne, and at one fourth of the expense: Take of the essence of bergamot, lemon peel, lavender, and orange flowers each one ounce, 15 ounces of the spirit of rosemary and of the spirituous water of balm, 7½ pints of strong alcohol. Mix the whole together, and let the mixture stand quiet for a fortnight. Put this in a glass retort, placed in a sand or water bath, the latter of which may be heated by a lamp, and lute a glass receiver to the beak of the retort. The water-bath being kept boiling, the mixture in the retort will distil over into the receiver, which should be kept cool with wet cloths. It should be kept for some time in a very cold cellar, or an ice-house.

6210. *Another Receipt.*—Distil as before, in a water-bath, 3 ounces of essence of bergamot, 3 ounces of essence of lemons, 1 drachm of oil of rosemary, 1½ ounce of essence of neroli, 1 ounce of oil of lavender, and 12 pints of alcohol.

6211. *Another.*—Mix two drachms of essence of citron and of bergamot, and 1 ounce of lemon peel, ½ drachm of oil of lavender, 10 drops of essence of orange flowers, 3 drachms of tincture of benjamin, and 2 drops of oil of rosemary. The most celebrated maker of eau de Cologne is Jean Farina, of Cologne.

6212. *Eau de Lis.*—Put highly rectified spirit of wine and oil of amber into a bottle, in the proportion of four pounds of the former to one ounce of the latter. Let these remain five days, shaking the bottle from time to time, by which means they will combine. Add to this four ounces of the best amber, powdered, and let the whole digest for three days. Having decanted this clean, add to it sixteen pounds of the strongest spirit of sal ammoniac and eight pounds of highly rectified spirit of wine. Take care the amber be genuine, for a great deal of what is sold for amber is a fraudulent composition.

6213. *Eau de Cannes.*—Take of fresh-gathered leaves of balm a pound and a half; the recent yellow rind of lemons, four ounces; nutmeg and coriander, each two ounces; cloves and cinnamon, each one ounce; the ingredients being sliced and bruised, pour upon them six pounds of rectified spirits of wine and three pounds of balm water. Digest the whole for three days, then draw off six pounds by distillation.

6214. *The French prepare a great variety of scented spirits,* in which are numerous ingredients, of which the following may serve as an example: *Spirit of Cytherea.*—1 quart of spirit of violets, 1 of jessamin, 1 of tuberose, 1 of clove gilliflower, 1 of roses, 1 of Portugal, and 2 of orange-flower water.

6215. *The following general directions are given for gathering and preserving leaves, flowers, roots, and sweet herbs for the purpose of distillation,* or for seasoning in cookery: Vegetables should be gathered in dry weather, and when no dew is upon them; they should be gathered fresh every year, and those which have been longer kept should be thrown away. Roots, for the most part, are to be dug up before their stems or leaves shoot forth. Barks are to be collected in the spring, when they are most easily separated from the wood. Petals should be gathered after the flowers have fully expanded, and before the seeds are mature; flowers, in general, when they are just full blown; seeds when they are ripe, and before they drop from the plant; they ought to be preserved in their seed vessels.

Some vegetables are to be used in their fresh state; others are first dried. When the latter is the case, they should be dried as quickly as possible, that their principles may be the least dissipated; for this purpose, they should be spread out in thin layers in baskets, or strewed upon a sieve, according to the nature of the substances, and exposed to the gentle heat of a stove or a common fire, so as not to alter their colour; when the leaves begin to shrivel, they should be turned frequently, and the heat should be continued till they begin to crumble in the hand. When perfectly dried, they should be preserved in glazed jars closely covered, not in paper bags, as often directed, and kept in a dry and warm situation. Some plants, the essential oils of which are very volatile, require to be powdered immediately when dried, and to be preserved in well-stopped opaque bottles. The greater part of the oils prepared for perfumery and medicine are from dried plants.

6216. *Steam affords a very excellent and regular heat for drying many substances,* such as leaves of various kinds. For this purpose, nothing more is necessary than a common tea-kettle to generate the steam, and a metal pipe fixed on to its spout, and connected with a tin box, about eighteen inches or two feet long, or any other size that may be convenient. Near the top of this box a tin cover is to be fixed, having circular holes cut in it to receive capsules or any other vessels, into which the substances to be dried are put, the bottoms of them being exposed to the steam, which fills the box. When a quantity of leaves are to be dried, a tin tray fits on the top of the box to hold them, and the circular holes are left open to suffer the steam to come to the bottom of the tray. The application of this principle of using steam heat may be varied in an infinity of ways, as it is easily conducted by means of pipes to any place in the apartment.

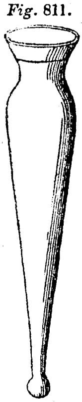
6217. *Aromatic flowers may be preserved for distillation* by the following method: Bruise the petals with salt, three pounds of rose leaves with a pound of common salt. Put the paste into an earthen jar, or water-tight barrel. This must be kept in a cool place. When it is wanted for distillation, a quantity of this paste may be put into the still with twice its weight of water. By applying heat in the usual way, the distilled water comes over perfumed with the essential oil. This process may be performed at any time of the year. Some chemists have been of opinion that herbs and flowers, moderately dried, yield a greater quantity of volatile oil than if they were distilled when fresh. It is, however, improbable that the quantity of volatile oil will be increased by drying; on the contrary, part of it will be dissipated and lost; but drying is useful in other ways, either by diminishing the bulk of the substance to be distilled, or by causing it to part with its oil more easily.

CHAPTER II.

TINCTURES AND EXTRACTS.

6218. *A tincture is a solution of any coloured substance in spirits of wine.* Rectified spirits of wine is the direct menstruum of the resins and essential oils of vegetables, which, not being soluble in water, or in a very small degree, cannot be extracted by it. Pure alcohol dissolves the greater number of the active principles of vegetables, except the ligneous fibre; viz., sugar, resin, extractive, tannin, camphor, the essential oils, several acids, and the narcotic principle. Gum is soluble in water, but not in alcohol; and rectified spirit, containing a portion of water, dissolves gum resins, which are intermediate between gum and resin. Pure alcohol is seldom required in the formation of tinctures, rectified and proof spirit being adequate for most purposes. Tinctures are not liable to suffer spontaneous decomposition, as is the case with infusions and decoctions; and if the bottles containing them be closely corked, they may be kept for any length of time unchanged. When spirituous tinctures are evaporated till they are of a thick consistence, they are called *balsams*.

Fig. 811.



6219. *Tinctures are prepared* by pounding the ingredients to be acted upon, putting them into a close vessel with alcohol or spirits of wine, and assisting the solution by a temperature not exceeding 80°, at which heat, by allowing the menstruum to act upon the ingredients for a sufficient time, all the principles that are soluble in them are extracted. The liquid should then be passed through filtering paper: the balneum mariæ is the best method of applying the heat, and the vessel should be frequently shaken during the digestion.

6220. *Tinctures may also be prepared rapidly* by moistening the pounded materials with some of the spirit intended to be used to the consistence of a thick paste; then putting it into a percolator, *fig.* 811, and pouring over it the remainder of the spirit. As it passes through the paste, the spirit dissolves the soluble matter, and drops as a tincture into a bottle placed to receive it. When it ceases to drop, water should be poured into the percolator, which will draw out the tincture without mixing with it. A piece of rag should be tied over the lower orifice of the percolator.

6221. *Tincture of Lemon Peel.*—This is a very easy and economical way of preserving the aromatic flavour of lemon peel. Whenever a lemon is used, pare the rind off very thin, and put it into a wide-mouthed bottle containing brandy or proof spirit. The spirit will, in a few weeks, be strongly flavoured.

6222. *Dr. Kitchener's Quintessence of Lemon Peel.*—Procure a drachm of the essential oil of lemons, and mix it gradually with two ounces of the strongest rectified spirit. This possesses all the delightful fragrance and flavour of the freshest lemon peel. A few drops on the sugar put into punch instantly impregnates it with as much of the flavour as is obtained by the troublesome and inelegant process of rubbing the sugar upon the rind of the lemon. It is likewise admirable for flavouring blanc-mange, jellies, negus, custards, and everything for which the aromatic flavour of the lemon is wanted.

6223. *Tincture of Ginger, improperly called Essence of Ginger.*—Infuse three ounces of grated ginger and two ounces of the thin parings of the rind of lemons in a quart of brandy or proof spirit.

6224. *Tincture of Cayenne, improperly called Essence.*—Steep half an ounce of Cayenne pepper in half a pint of brandy or wine for a fortnight. Pour off the clear liquid. This is preferable for preparing fish sauces and many other articles of cookery, as the flavour is instantly and equally diffused; and it is likewise more easy and accurate to season with this than with the pepper itself.

6225. *Tincture of Chili.*—Steep 50 fresh red Chilies in half a pint of brandy for a fortnight; this has the same properties as the last. This is also usually called essence of Chili, but improperly.

6226. *Essence of Lemon or Orange Peel, by Dr. Kitchener's Method.*—Wash and brush clean the lemons; let them get perfectly dry; take a lump of sugar, and rub them till all the yellow rind is taken up by the sugar; scrape off the surface of the sugar into a preserving pot, and press it hard down; cover it very close, and it will keep some time. This method of preserving an essential oil is termed an *oleo-saccharum.*

6227. *Tincture of Allspice, usually called Essence of Allspice.*—This is very useful in making mulled wine, and in flavouring gravies, for which a few drops will suffice. It is made by adding a drachm of oil of pimento to two ounces of strong spirit of wine.

6228. *Another Method.*—Steep three ounces of allspice, bruised, in a quart of brandy. This is used for the same purpose as the last.

6229. *Tincture of nutmeg* is made as that from allspice.

6230. *Tincture of Cinnamon.*—Macerate three ounces of bruised cinnamon in a bottle of French brandy or rectified spirit. This was at one time much in vogue as a stomachic, and is still considered as a useful remedy.

6231. *Compound Tincture of Cinnamon.*—Macerate for fourteen days, in two pints of proof spirit, six drachms of cinnamon bark, bruised, three drachms of cardamom seeds, bruised, two drachms each of long pepper and ginger; filter.

6232. The *spirits*, or, as they are usually called, *essences*, of nutmeg, cloves, and cinnamon are prepared by adding the essential oils to brandy or rectified spirit.

6233. *Spirits are also prepared from various sweet and savoury herbs,* which are extremely convenient in culinary preparations. These are obtained by steeping the dried herbs in brandy or proof spirit.

6234. *Dr. Kitchener's Soup-herb Spirit.*—Infuse for ten days, in a pint of brandy, half an ounce each of lemon thyme, winter savory, sweet marjoram, and sweet basil, two drachms of lemon peel, grated, the same of eschalots, and one drachm of celery seed.

6235. *Dr. Kitchener's Spirit of Savoury Spice.*—Infuse for ten days, in a pint of brandy, one ounce of black pepper, half an ounce of allspice, and a quarter of an ounce of nutmeg, grated.

6236. *Dr. Kitchener observes*, that "cooks who are jealous of their reputation, and housekeepers who value their health, will prepare these articles, and some other ingredients for sauces above mentioned, at home; there are quite as many reasons why they should as there are for the preference usually given to home-made bread and home-brewed beer."

6237. *The term extract* refers more properly to the mode of preparation than to the nature of the substance prepared. Although chemists in general have described *extractive* or the extractive principle as a peculiar proximate principle in vegetables, yet it is now doubted whether there is any one principle to which this name can with propriety be applied. Making an extract consists in dissolving by water, spirit, or any other menstruum, such parts as are soluble, and concentrating or inspissating this solution by heat to a thick consistence, or sometimes to entire solidity. Hence we find in an extract generally a great variety of substances, as mucilage, sugar, tannin, resin, gluten; in short, whatever happened to be present, and could be dissolved by the menstruum employed. If water alone is employed, the solution is called a *watery* extract; if alcohol, or proof spirit, then the produce is a *spirituous* extract.

6238. *To make a watery extract*, the substances are generally boiled in water, the decoction is strained, and then boiled down till it has attained the required consistence, and, perhaps, gently dried on a stove. If a spirituous extract be required, a tincture of the substance is first made, and this is evaporated gently in a water or sand bath; or, a distilling apparatus may be employed, and thus the spirit be saved. In performing the operation of making watery extracts, a higher temperature than boiling water must not be employed, and yet the evaporation must be effected as quickly as possible, by having the evaporating vessel broad and shallow, and set in a water-bath. Some extracts are made by a mixture of spirits and water, it being found that certain plants contain both a resin and a gum, the first being soluble only in spirit, and the latter in water, as extract of jalap, of Peruvian bark, &c. Some extracts require long digestion.

To prevent too great a heat affecting the properties of extracts, a method has been invented by Mr. Barry for preparing them *in vacuo*, that is to say, in vessels from which the air has been expelled, by which the virtues of the plants are more effectually preserved, from the boiling or evaporation being effected with less heat than in the common pressure of the atmosphere; that is, less than 212°. These extracts are generally green, and contain saline crystals, but some of them will not keep. Extracts are chiefly used medicinally, as extract of liquorice, of aloes, of rue, &c.

CHAPTER VII.

ADULTERATION OF ESSENTIAL OILS.

6239. *The adulteration of essential oils* is very common, since many of them are of high price, and come from abroad. They are sophisticated in several ways.

1. They have expressed oils mixed with them. 2. They are mixed with alcohol. 3. They are adulterated with cheaper essential oils. *If any essential oil be adulterated with expressed oil*, it is easy to discover the fraud by adding a little spirit of wine to a few drops of the suspected oil, and shaking them together; the spirit will dissolve all the oil that is essential, or procured by distillation, and leave all the expressed oil that was mixed with it untouched. *When an essential oil is adulterated with alcohol*, or rectified spirits of wine, this may be done in any proportion, up to that of an equal quantity, without being easily discoverable either by the smell or taste. The way to discover this fraud is to drop a few drops of the oil into a glass of pure water; and if the oil be adulterated with spirit, the water will immediately turn milky, and by continuing to shake the glass, the whole quantity of spirit will be absorbed by the water, and the oil left pure at top. *If an essential oil be adulterated by another but cheaper essential oil*, the detection is more difficult. As all volatile oils agree in the general properties of solubility in spirit of wine, indissolubility in water, or miscibility with water, by the intervention of certain intermedia, volatility in the heat of boiling water, &c., it is obvious that they may be variously mixed with each other, or the dearer sophisticated with the cheaper, without the possibility of discovering the fraud by any ordinary trials; and, indeed, it would be of more advantage to the purchaser if he had infallible criteria for the discovery of the *goodness* of the manufacture than of the *genuineness* of each oil; for genuine oils, from inattention in distillation, or long and careless keeping, and other causes, are often weaker, both in smell and taste, than the common sophisticated ones. The smell and taste seem to be the only certain tests of which the nature of the thing will admit. Most of the volatile oils, indeed, are too hot and pungent to be tasted with safety; and the smell of the subject is so much concentrated in them, that a small variation in this respect is not easily distinguished, but we can readily dilute them to any degree. A drop of the oil may be dissolved in spirits of wine, or received in a bit of sugar, and dissolved by that intermedium in water. The quantity of liquor which it impregnates with its flavour, or the degree of flavour which it communicates to a certain determinate quantity, will be the measure of the degree of goodness of the oil.

6240. *Some consider the specific gravity* of essential oils as a certain criterion of their genuineness. This, however, is not to be absolutely depended upon; for the genuine oils, obtained from the same subjects, often differ in gravity as much as those drawn from different ones. Cinnamon and cloves, whose oils usually sink in water, yield, if slowly and carefully distilled, oils of great fragrancy, which are specifically lighter than the water employed in their distillation; while, on the other hand, the last runnings of some of the lighter oils prove sometimes so ponderous as to sink in water. Some plants and barks yield both a light and a heavy oil

BOOK XXI.

JEWELRY.

GENERAL REMARKS.

6241. *Jewels comprehend all those ornaments* of dress in which the precious gems form a principal part. Some of these constitute very expensive, although, on frequent occasions, indispensable articles of dress; the nature and distinctive qualities of the gems should therefore be well understood.

6242. *The business of the jeweller* is, in strictness, distinct from that of the goldsmith; the latter, working only in gold, does not employ any precious stones, whereas the jeweller employs gold merely to hold, or *set*, as it is called, the several gems. The jeweller, however, does not cut the gems; he procures them ready cut from the diamond cutter and the lapidary, and his business is merely to group and set them.

6243. *Great care should be taken in the purchase of jewels*, and in particular to ascertain that the several stones are genuine, or are really what they are called. Some precious stones are easily known, but others are extremely difficult to be distinguished; and though it may appear extraordinary, yet it is a fact that many jewellers in England, particularly the working jewellers, are but indifferently acquainted with several of the stones they have to make use of, sometimes deceiving their customers through their own want of knowledge. At the same time, it is also true that some of them, possessing the requisite information, employ it to practise fraud, by changing the colour of stones by heat, by putting foil behind one kind of stone to make it pass for another, and by similar tricks. One caution we may give. Paste, a kind of coloured glass, is sometimes sold for the gems they imitate; but this may easily be detected, for glass may be scratched by a good file, whereas none of the gems can.

6244. *To determine accurately the species of precious stone* when there is any doubt, the specific gravity sometimes offers a guide, as almost every one has its particular weight; but this requires a delicate hydrostatic balance, and an acquaintance with its use, as well as the proper weight of stones. As an example: if a stone of a fine crimson red is called an Oriental ruby, the purchaser must ascertain whether it be not a Siberian tourmalin, or ruby spinelle, which are of inferior value. For this purpose, the stone must be unset. Suppose its weight in air to be 100 grains, and he finds it reduced to 69 grains when weighed in water. Now, a real sapphire of the kind called Oriental ruby, which weighs 100 grains in air, would have weighed 76·6 in water; a spinelle ruby of 100 grains would have weighed 72·2 in water; and a Siberian tourmalin would weigh only 69 grains in water. From this, therefore, it appears that the stone offered as an Oriental ruby is only a red or Siberian tourmalin.

6245. *The cutting of gems* into the usual shapes, and the polishing of them, are performed by the lapidary, who employs diamond powder for this purpose, as the hardest thing known. In slitting stones, the diamond powder is used with a fine wire coated with it, and which acts like a kind of saw; in grinding down surfaces, the diamond powder is put upon a wheel of soft metal, in which it is imbedded.

6246. *Flaws in rough, unwrought stones* may be made more perceptible than when viewed in air, if they are plunged into water; but still more so if they are immersed in some denser fluid, as Canada balsam, oil of sassafras, fluid oil of anise seeds, &c.

6247. *There is much confusion in the common mode of naming the precious stones used in jewelry;* and many jewellers themselves are ignorant of their proper names, as distinguished by eminent mineralogists. These valuable substances were formerly classed and named according to their colours; hence all red gems possessing a certain degree of hardness were called rubies; the blue, sapphires; the yellow, topazes; the purple, amethysts, &c. But at present gems are not classed by mineralogists merely according to their colours, but according to the nature of their crystallization, their chemical composition, or the earths of which they consist, and their specific gravity. The true classification of gems or precious stones, according to the modern system of mineralogy, is into the diamond, the varieties of corundum, the sapphire, the emerald, the topaz, the spinelle, the garnet, the tourmalin, &c. Each of these differs from the rest in its crystallization, hardness, and chemical composition, forming a separate and peculiar mineralogical species; and as each of these appears under various colours, colour alone cannot be considered as a complete distinction. Besides the stones just mentioned, there are a few others of less value, which we shall also describe. We shall treat of these according to their mineralogical distinctions, at the same time mentioning the popular names used by jewellers.

SECT. I.—DIAMOND.

6248. *The unrivalled brilliancy of this gem* has always attracted universal admiration, and among ornaments it has ever occupied the highest rank. No other substance, natural or artificial, can rival its lustre, rich with prismatic colours. The beauty of other gems is almost lost to the distant beholder; the diamond alone diffuses its starry radiance to the most distant parts of the assembly, and has acquired, by common consent in all ages, a prodigious value that continues undiminished. But notwithstanding the immense value of diamonds of large size, small stones are sufficiently abundant to be within the reach of most persons in easy circumstances, and are therefore in very general request.

6249. *Large diamonds* have ever been extremely rare; and a few, celebrated for their magnitude and beauty, are in the possession of sovereign princes.

1. The largest diamond on record is mentioned by Tavernier the traveller as having been in the possession of the Great Mogul; it weighed 296 carats, and was found near Golconda in 1550. Its size is about half of a hen's egg. 2. A very large diamond, weighing 193 carats, is said to have been the eye of an idol, and about the size of a pigeon's egg. It was stolen by a French soldier, who escaped with it to Madras; and it came subsequently into the hands of Prince Orloff, of whom the late Catherine, empress of Russia, purchased it for £90,000, an annuity of £4000, and a title of nobility. 3. The Pitt or Regent diamond is said to have been found in Malacca, and was purchased by a Mr. Pitt for £20,000; it weighed 210 carats. He brought it to London, and had it cut, which reduced its weight to 136½ carats; and he then sold it to the Duke of Orleans for £100,000. It is now in the crown jewels of France, and may be said to be the finest brilliant in Europe. 4. The Emperor of Austria possesses the largest yellow diamond known, weighing 139½ carats; this formerly belonged to the Grand-duke of Tuscany. 5. The Pigot diamond is valued at £40,000, and is said to have been sold lately to the Pacha of Egypt by a jeweller in London. It is of the finest water. 6. A green brilliant, of exquisite beauty and great size, but of irregular form, is worn by the King of Saxony, when in court dress, as a button to the plume in his hat. 7. Several fine diamonds are among the crown jewels of our royal family. Models in glass of the principal diamonds in Europe may be purchased.

6250. *The Greek and Latin name* of this precious gem is *adamas*, invincible, in allusion to its extreme hardness, whence is derived the English adjective adamantine.

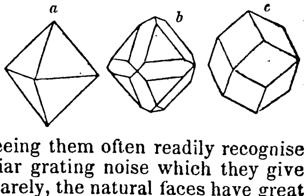
6251. *It differs from all other gems* in not being composed of earth, but of carbon; and it is remarkable that Sir Isaac Newton conjectured that it was a combustible body long before it was discovered by experiment to be so, from observing its great power to refract light. The colours of diamonds are various. The finest are colourless in themselves, and have only what they derive from refracting the rays of light. These are said to be of the purest water. Some have a tinge of pink, red, blue, or green, which are next in estimation. Yellow diamonds are common, though much esteemed. Brown diamonds are less valuable, and still less so are those which are cloudy or have flaws.

6252. *Diamonds are always found* in the loose, alluvial soil, and not imbedded in ancient solid rocks like the other gems. India and Brazil are the two chief countries which produce them: in the former, Golconda, Visapour, Bengal, and Borneo are the principal diamond districts. What are called diamond mines are places where the loose sand and other stony materials are washed in water, to separate the precious stones: a great number of persons are employed in these works. It is said that the diamond mines of India are nearly exhausted, and that Brazil now chiefly supplies the markets of Europe; the mines are the property of the crown, and strangers are not permitted to visit them.

It is a curious fact in the history of Brazilian diamonds, that, when they were first discovered in that country, they were kept as pretty pebbles, and used for counters by card-players, long before their true nature and value were ascertained by the Dutch consul, who accidentally saw them.

6253. *Rough diamonds*, that is, diamonds in their natural state, before they are cut by the jeweller, are crystallized, and when perfect exhibit regular forms, of which the simplest is the octohedron, *a*, *fig.* 812, or modifications of it, as *a*, *b*, *c*, without the polish and brilliancy which is given by art; indeed, in their rough, unpolished state they would not be readily distinguished from common pebbles by persons not practised in examining them. In general, also, their angles have been much rubbed off, so that they appear nearly round, resembling, in a considerable degree, gum Arabic. Those, however, who are in the habit of seeing them often readily recognise them among other pebbles, and this partly by a peculiar grating noise which they give when rubbed against a pebble: occasionally, though rarely, the natural faces have great brilliancy. The diamond is the hardest of all known substances, and it is supposed by some not to be capable of being broken by the blow of a hammer; but though the substance is extremely hard, it is not difficult to fracture: a slight blow will cause it some-

Fig. 812.



times to split, and the sharp side of a cut diamond is often chipped off by careless management.

6254. *Attempts have been made to fabricate the diamond* by chemical means, but hitherto always without success: the idea is, however, not absurd, since we know its composition to be pure carbon only; and could the means of crystallizing carbon be discovered, this object would be attained. Diamonds would then be more useful to mankind in the arts, though their great value might cease to exist.

6255. *We hear sometimes of Cornish diamonds, Bagshot diamonds,* &c. These are merely small, transparent quartz crystals which have been rolled and water-worn, and are found among the sand or gravel on the surface; they are sometimes cut and polished, and, though brilliant and sparkling, have little of the splendid tints of the diamond, and do not come near to it in hardness, being only a little harder than glass: they are of very little value.

6256. *The art of cutting diamonds,* the hardest gems in the world, is so curious that we shall describe it. This gem may be split by a steel tool, if a blow be applied; but to effect this it is necessary to have a perfect knowledge of its crystallized structure, because it will only split in the direction of the laminæ formed by the crystallization, and the workman cannot form facets at pleasure by splitting. To produce the faces which are required for exhibiting the gem in all its beauty, the process called *cutting* is resorted to, but which is, in fact, abrasion rather than cutting, and was first discovered in Europe, in 1476, by Louis de Berghen, of Holland, though probably known in China and Hindostan in very remote periods. For this purpose, the diamond to be cut is fixed on the end of a stick or handle, in a small ball of cement, that part which is to be reduced being left to project. Another diamond is also fixed in a similar manner, and the two stones are rubbed against each other with considerable force, until they are ground away as much as is necessary to produce a facet. Other facets are formed in a similar manner by shifting the position of the diamonds in the cement. When the faces are thus completed, they are next to receive an exquisite polish. Nothing is capable of polishing the diamond except its own powder, which has been collected for this purpose in a small box during the process we have just described. The stones are now imbedded in soft solder, contained in a small copper cup, the face to be polished being left to protrude. A flat, circular plate of cast iron is then charged with diamond powder produced in the abrading process, and the stone is held against this plate, while it is made to revolve until the polish is complete. Those diamonds that are unfit for working on account of their imperfections are sold under the technical name of *bort.* These are broken by repeated blows in a steel mortar, until they are reduced to powder, for various purposes.

6257. *The diamond is a substance of considerable utility in the arts,* independently of its value as an ornament. Fine drills are made of small splinters, which are used for drilling holes in rubies and other hard stones used by watch jewellers in the best kind of clock-work, gold and silver wire-drawers, and others who require very fine holes drilled in such substances. These drills are also used to pierce China-ware, where rivets are to be inserted; also for piercing holes in artificial enamel teeth, or any vitreous substances, however hard. The fine powder is used for grinding down other very hard stones, none of which can be cut or engraved without this material; arms, crests, cameos, intaglios, are engraved upon carnelian, onyx, agate, &c., by means of diamond powder.

6258. *Diamonds are cut and polished in particular shapes,* which have received the names of *brilliant, rose,* and *table-cut.*

6259. *The brilliant* is in the highest estimation, as it is the form which shows to the greatest advantage the peculiar lustre of the gem. It may be considered as composed of two truncated pyramids placed base to base, the upper pyramid being more deeply truncated than the lower one.

6260. *The rose diamond* is the form given to those stones the spread of which is too great, in proportion to their depth, to admit of being brilliant cut without a great loss of substance. It is formed by covering the whole surface of the stone with equilateral triangles.

6261. *The setting of diamonds* is of great importance, and depends partly upon their quality. The finest brilliants are always *set open,* that is, without a back. Shallow brilliants, that have a great surface, are generally *set close,* or with a back of a black substance; and then frequently much ingenuity is exercised, an inferior stone being sometimes made, by concealing defects, to appear like a perfect brilliant. What are called *foils* are thin leaves of metal placed under a precious stone, in order to increase its brilliancy or to give it a different colour. They are of gold, silver, or copper.

6262. *Diamonds are bought and sold by weight,* for which a peculiar standard, called *a carat,* is universally adopted. The carat is an Indian denomination of weight, and 150¼ carats are equal to 1 oz. Troy. The carat is divided into four parts, called grains; and the grains are subdivided into fractional parts, which are ascertained by scales with great nicety. Sometimes the weight is expressed simply in grains; as, a diamond of two carats, or of eight grains. The smallest flaw greatly lessens their value; and the same happens if they be tinged with any dull tint of yellow or brown, though defects are not unfrequently concealed by the mode of setting.

6263. *Rough diamonds are valued* by squaring the number of carats they contain, and multiplying the product by 2, which will give the value in pounds sterling. Thus, for a rough diamond weighing 4 carats, $4 \times 4 \times 2 = 32l.$; and so in other cases. As wrought diamonds are supposed to have lost half their original weight in cutting and polishing, the square of double their weight, in a finished state, must be multiplied by two: thus, to value a wrought diamond of 3 carats, $6 \times 6 \times 2 = 72l.$ Or the weight may be squared, and the product multiplied by 8, which will give the same result: $3 \times 3 \times 8 = 72l.$ Brilliants from 1 to 2½ grains are worth from 7*l.* to 8*l.* Those from 5 to 6 grains are worth from 14*l.* to 15*l.* Brilliants of 2 carats are worth from 28*l.* to 30*l.*; those of 4 carats are worth 100*l.*; those of 5 carats are rare; they may vary from 180*l.* to 200*l.*

6264. *In the purchase and sale of diamonds by private individuals*, it should be remembered that there is a material difference between the jeweller and the diamond merchant, though sometimes, but not often, the two trades are combined. The diamond merchant is a trader who buys rough diamonds, and employs his men to cut and polish them. He offers them for sale in this state, in single stones or in lots, agreeably to the desire of the purchasers. They are not set, but laid openly on a sheet of white paper, so that there can be no possibility of concealing flaws or enhancing beauty by any of the artifices often practised in setting. The diamond merchants are very limited in number, and are generally men of opulence, well acquainted with the details of the art of cutting, but little known except to the importers of rough diamonds and to the *trade*. Persons who, from the pressure of necessity or from other motives, may be induced to convert their diamonds into specie, should carry them to the diamond merchant; he will take them from their setting, weigh them, and offer the fair market price for them, without taking advantage of the inexperience or the embarrassed feelings of the owner.

The business of the jeweller is, to set the diamonds in such form as is most tasteful and agreeable to his customer, and so as to show them to the greatest advantage. He purchases from the diamond merchant such stones as he has a demand for, or supposes to be saleable, and forms them into necklaces, ear-drops, rings, &c. Setting costs but little; a hoop-ring consisting of 12 stones, suppose the 12 stones to weigh 1 carat, may cost, on an average, about 24*s.*; a cross, 13 or 14 stones, gold and open, 50*s.*; a necklace 16 inches long, and composed of 28 or 32 stones, might cost, to set in gold, about 15*l.* The diamond merchant charges for his diamonds a regular wholesale price, and gives, perhaps, six months' credit. The jeweller charges what he thinks proper above the price which he has given, or according to the nature of the jewel; or, if it be made to order, according to the opinion he may entertain of his customer.

Diamonds, when set, always appear larger than they really are; and even the most experienced dealer will not venture to pronounce on the exact value of a diamond when set. As their value is ascertained by their weight, a working jeweller can take them out of the setting in a few minutes, when their proper value can be ascertained.

6265. *Ladies who purchase jewels* should always inquire what weight of diamond is in any particular jewel, and of what weight are certain single diamonds; how many of the smaller stones, for instance, are in a carat; by which means they will easily ascertain the total weight of the diamonds that the article contains. In having their diamonds re-set, great care should be taken that the stones may be identified when they are returned. A judicious precaution is, to draw the flower or other device which they intend to have made up, and to assign to each stone its position in the group.

6266. *The trade of the diamond cutter* is wholly distinct from that of the lapidary, whose business it is to polish the inferior gems. The diamond cutters of England are confessedly the best in Europe, but their number is, unfortunately, so small as to occasion many stones to be sent to Holland, where, from the greater number and more active competition of the artists, the price of workmanship is considerably lower; but the work is said to be inferior. Brilliant-cut diamonds are so much superior to the others, that frequently rose-cut have been re-cut into brilliants, although, as already observed, at a great loss.

6267. *Diamonds are always equally in fashion*, but the mode of setting them varies according to the caprice of taste or the desire of novelty. Hence the jeweller has perpetual opportunities of exercising or displaying the inventive élegance of his taste in the assortment of hues and the arrangement of groups. He will cluster together the smaller stones so as to enhance the effect of the whole; the larger and more perfect ones will generally be set open, and displayed to the greatest advantage, while the inferior ones will be assisted by setting them solid in black, or, if need be, with coloured foil. But whatever be the occasion that calls forth his art, whether the construction of a star, a bandeau, a tiara, a plume, a necklace, or an ear-drop, he should bear in mind that his greatest merit is the concealment of his art. The display of belts and borders of gold can add nothing to the superlative lustre of the diamond.

6268. *Diamonds are a species of property* little liable to fluctuation, as their value continues nearly uniform; but for diamonds of great magnitude the purchasers are very limited in number.

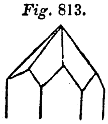
SECT. II.—GEMS BELONGING TO THE SPECIES CORUNDUM.

6269. *Corundum is the name of* an extremely hard mineral substance, found chiefly in India, and used there extensively for cutting and polishing the hardest stones. It occurs in grains, and imbedded, in small masses, in granite, and is of various shades of white, brown, green, red, &c. The common corundum is usually impure; but when this mineral is in its purest state, it constitutes some of our most precious gems, as the sapphire and the ruby; and it includes the gems denominated by jewellers the Oriental amethyst and the Oriental topaz. The basis of all these is the earth alumina, and the purest state of the species corundum consists of little else. We shall describe its proper varieties, and also the gems as designated by the various names given by jewellers.

Sapphire.

6970. Sapphire is the purest, or perfect state of corundum, and is the hardest of all earthy minerals, being inferior in this respect only to the diamond; the hardness is therefore one of its distinctive characters. What is considered as the most perfect, or Oriental sapphire, is of a clear bright blue colour, with a high degree of translucency; but it is also pale blue, and sometimes violet blue, or cloudy. Sapphires are also occasionally colourless. When they are violet blue, they are usually called by the jewellers Oriental amethyst (see "Amethyst"); when they are yellow, they are termed by the jewellers Oriental topaz. The latter are improper terms, since amethysts and topazes are quite different stones. Some sapphires show a pale reddish or bluish reflection, and are then termed *Girasol sapphires;* others, cut *en cabochon*, exhibit the appearance of a silvery star of six rays, in a direction perpendicular to the axis of the natural crystal, a variety that is termed *asteria*. The primary form of the crystals of sapphire is that of a slightly acute rhomboid, which is the same as that of common corundum; but the crystals usually occur under a secondary form of a six-sided prism variously terminated (*fig.* 813), and also in rolled masses. The crystals are readily cleavable in one direction, parallel to one of the planes of the primary rhomboid, showing the cleaved surface very brilliant; but it is extremely difficult to produce cleavages parallel with the other planes of the rhomboid. The finest sapphires come from Pegu and Ceylon, where they are found only in the beds of rivers, often in rounded fragments, generally small, and seldom exceeding the size of a hazelnut. Blue sapphires are not uncommon, and those of ten or twenty carats are easily procured, being of the value of from twenty to sixty shillings per carat, according to their beauty. Sapphires are sometimes substituted for diamonds, by exposing them to a strong heat, which destroys their colour, but improves their hardness and transparency; and this kind of fraud would be difficult to detect by any one who was not a good judge of these stones.

Fig. 813.



Ruby.

6271. The ruby is a gem which, when of the kind called Oriental (and which we stated to be mineralogically of the same species as the sapphire), is of great beauty and value. *The true, or Oriental ruby*, when perfect, is the most valuable of the gems next to the diamond; the colour is a fine, deep, cochineal red, having a richness of hue unrivalled; occasionally it is rose-red, or has a tinge of violet. The monarchs of Pegu, Siam, and Ava possess rubies of the greatest beauty, as the sovereigns of India had the finest diamonds. It is said that none equal to these are in the possession of European princes. The finest in Europe is said to belong to Mr. Hope. Rubies of ten carats are extremely rare; one weighing twenty-two grains sold for 160*l*. A perfect stone of six grains is rare, and falls little short of the value of a diamond; indeed, if some small rubies are very fine, they are of greater value than diamonds of the same weight. The natural crystal is in the form of a six-sided prism; it cleaves more readily than the sapphire, and is not so hard. It consists, according to Chenevix, of 90 parts alumina, 7 silica, and 1·2 of oxyde of iron.

6272. *But there is another stone, also sometimes called ruby*, which belongs to a different species, and is inferior in value and hardness. This is the *spinelle*, or *balais ruby*, which, when red or violet, has been called ruby; thus we have the Oriental ruby and the spinelle ruby. The crystallization of the spinelle is different from that of the sapphire, and, consequently, different from that of the Oriental ruby. It does not consist only of alumina, like the Oriental ruby, but contains also 8 per cent. of magnesia and 6 per cent. of chromic acid. It may be distinguished from the Oriental ruby by its inferior hardness and specific gravity. Its colour is usually some shade of red, as scarlet, cochineal, rose, violet, cherry, or yellowish red. When of a good colour, it is little less valuable than the Oriental ruby. Among lapidaries, the scarlet-red is sometimes called ruby spinelle; the pale or rose-red, the balais ruby. The red topaz has been called by the lapidaries the Brazilian ruby, and a variety of red quartz, Bohemian ruby.

Sect. III.—emerald.

6273. The emerald, in value, ranks next to the ruby. It is of a pure, beautiful, bright, and intensely green colour, when the stone is of the most perfect kind, called Oriental; hence the name *emerald green*. The colour, however, varies a little; sometimes it is paler, and the green less lively, or it is a pale blue, or yellowish. The form of its natural crystals is a six-sided prism, and it cleaves readily parallel to the axis of the prism. It is somewhat harder than quartz, but not so hard as beryl, though more difficult to cleave. Its composition, according to Vauquelin, is 64 parts silica, 16 alumina, 13 glucine, and 1·6 lime, glucine being the colouring matter. The finest emeralds come from Peru, where they have been found occasionally several inches in length. They are also found in Ceylon and Egypt; and in the latter country the ancients had emerald mines. A fine stone of four carats may be valued at 40*l.* per carat; and an inferior one, of one or two carats, at from forty to sixty shillings per carat. It is always cut by the lapidary into facets, and is frequently set surrounded by brilliants. Fine emeralds are extremely rare. The green tourmalin has been called the Brazilian emerald.

Sect. IV.—beryl.—aquamarine.

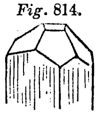
6274. The beryl is considered by some mineralogists to belong to the same species as the emerald; but it differs from it in hardness and composition, as well as in colour. The primary form of its crystals is a six-sided prism, terminated by a six-sided pyramid, truncated; and this is its usual form: the sides are striated longitudinally, whereas those of quartz, which its form resembles, are striated transversely, and it is harder than quartz. The crystals may be cleaved parallel to the planes of the prism, and more easily than those of the emerald. Its composition, according to Vauquelin, is 68 silica, 15 alumina, 14 glucine, 2 lime, and 1 oxyde of iron. The colour of the beryl is various shades of pale yellow, or green, or blue. The common beryl is scarcely employed in jewelry, on account of its numerous flaws and cracks.

6275. *The aquamarine* is a variety of beryl of a light, bluish, sea-green colour, of various shades. It derives its name from the Latin with reference to its colour. In hardness it is inferior to the topaz. Formerly it was of considerable value, but of late so many have been imported from Brazil, Siberia, and India, that their value is much reduced, except they are very fine. The best come from Ceylon. Large stones, from one to three or four ounces, are not uncommon. Small stones may be had for a few shillings each.

Sect. V.—topaz.

6276. The topaz is a particular species of mineral, occurring in crystals of the form of a rhombic prism, variously terminated (*fig.* 814). This prism is usually striated longitudinally. It cleaves readily at right angles to the axis of the prism. It somewhat resembles quartz, but is distinguished by the form of its crystals, by its superior hardness, and specific gravity. Both it and quartz scratch glass, but topaz scratches quartz. It is sometimes colourless and translucent, but usually has various pale shades of yellow, green, blue, lilac, or red. According to Vauquelin, it is composed of 50 parts alumina, 29 silica, and a quantity of fluoric acid, varying from 4 to 19 parts. It is found almost exclusively in the ancient primary rocks; and in Saxony, in a particular rock called Topaz Rock; these topazes are of a pale yellow. The Brazilian topaz is of a deep yellow, and becomes red or pink in a heated crucible, and then the price is augmented; it is also found there in rolled masses. Some from Brazil are beautifully pellucid, and are called *Minas Nova;* these have been abundantly employed in jewelry, and produce a fine refraction of light in pins and other ornaments. When topazes are naturally red, they have been called Brazilian ruby. There are also blue topazes, which have been called by lapidaries Oriental aquamarine. Yellow sapphires are by jewellers called, improperly, Oriental topaz; these nearly equal the diamond. Counterfeit pink topazes are sometimes made by interposing some colour between two thin plates of clear topaz, and then setting the whole; this fraud may be sometimes detected by holding the edge of the stone against the light, when the want of colour will be perceived. Similar impositions are practised with other stones. Various mineral substances, also, of other species, have been called topazes, and passed as such: thus, chrysolite has been called yellowish green topaz; yellow rock crystal, Bohemian or occidental topaz; and clove-brown and brown crystal have been named smoke topaz; all these are inferior in hardness to the true topaz. The topaz is easily counterfeited in glass paste; and some of the imitations are nearly as beautiful as the real stones.

Fig. 814.



Sect. VI.—chrysoberyl.

6277. This gem, called also *Cymophane*, is found chiefly in rounded pieces of a greenish colour, and somewhat opalescent; it is also found crystallized in prismatic forms, cleavable parallel to their sides. It is composed of 71·5 alumina, 18 silica, 6 lime, and 1·5 oxyde of iron. It is chiefly procured from Brazil and Ceylon. It has a particular play of light, and is so extremely hard that it has been sometimes taken for diamond. Good specimens are rare.

SECT. VII.—HYACINTH.

6278. This stone is sometimes, though rarely, of a brilliant appearance and colour, but is sometimes beautiful, of an orange-red colour, also of various tints of yellow, brown, or gray. When deprived of its colour by heat, it is said to have been sold for diamond. The best are from Ceylon. The *zircon* of Norway appears to be nearly the same mineral. The composition, which varies somewhat in different places, is about 70 per cent. of the earth called zircon, 25 silica, and 0·5 oxyde of iron. The form of its crystals is an octohedron. Except fine, this stone is not highly esteemed, being often full of flaws. The *jargon* of Ceylon seems to be a transparent, colourless variety, but it is not of much value.

SECT. VIII.—CHRYSOPRASE.

6279. This stone is rather rare, and is of a cloudy pale-green colour, having an agreeable appearance; it is translucent, and is nearly allied to the chalcedonies and carnelians; like them, it is never cut into facets, but is used for large bracelets, brooches, seals, &c.

SECT. IX.—CHRYSOLITE, OR PERIDOT.

6280. This is a stone found in volcanic rocks; and though of an agreeable colour, brownish, yellowish, or of various shades of green, yet having little brilliancy, it is little used in jewelry; it is sometimes made into necklaces, but is scarcely harder than glass, being scratched by the file. It consists of 43 parts magnesia, 39 silica, and 19 oxyde of iron.

SECT. X.—TURQUOISE.

6281. The turquoise is rare and much in request. It is destitute of the lustre which distinguishes most of the precious stones: it is opaque, and does not admit of a very high polish, but its colour is a fine celestial blue. There are two kinds of the substance called turquoise: one is a stone called *calaite*, and found chiefly in Persia, where it is in high estimation, and on that account few of the most beautiful specimens come to Europe; the other is fossil bone, coloured by phosphate of iron or carbonate of copper. The latter is liable to change in colour. The turquoise is cut spheroidal, and appears to most advantage when surrounded with brilliants or pearls. It is from the size of a pin's head to that of an almond. Malachite is sometimes sold for turquoise.

SECT. XI.—TOURMALIN.

6282. The tourmalin is occasionally used in jewelry. Common tourmalin is black and opaque, but there is a transparent precious kind, which is red, green, blue, or pink, and often sold for other stones. One of the most remarkable properties of the tourmalin is its becoming electric by heat or friction. The crystals of common tourmalin are often large, and scarcely employed by the jeweller.

SECT. XII.—MOONSTONE.

6283. The moonstone is a variety of feldspar called *adularia*, and is beautifully translucent, of a milky colour, and having a remarkable play of light, amounting to a slight pearly lustre, and sometimes iridescence, which contrasts agreeably with the delicate bluish tint of the stone, whence its name. It is used for ear drops and rings, and, when fine, sells for a high price. The best comes from Ceylon. It consists of 64 parts of silica, 20 alumina, 2 lime, and 14 potash.

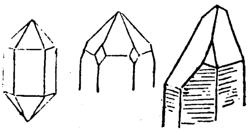
SECT. XIII.—GARNET.

6284. Garnet is a very common mineral, though beautiful specimens, called the precious garnet, or *almandine*, are classed with gems. These are usually of a deep red. The finest come from India. When large and of a fine colour they are valuable. They are much worn in beads, and are also set; they are chiefly used in mourning. What is called the Oriental is brought from Sirian, in Pegu, improperly called by lapidaries Syrian garnets. They appear to be the carbuncle of the ancients. There is also the Bohemian garnet, which is the *pyrope* of some mineralogists. Common garnet, not fit for jewelry, being ill-coloured and opaque, or only slightly translucent, is, in many countries, quite common, and is even used as a flux for ores. There is also the *melanite*, or black garnet, found in volcanic rocks, and worked into necklaces at Naples; but black glass is not unfrequently made to pass for it to English travellers. Garnet consists, according to Vauquelin, of 43 parts of silica, 16 alumina, 20 lime, and 16 oxyde of iron. Some, as the large common garnets of Fahlun, have no lime. The primary form of the crystals is the rhombic dodecahedron. They usually occur in the most ancient rocks: some are found in this country, and particularly in Cornwall. Garnets are hard enough to scratch quartz, and, of course, much harder than glass, by which glass counterfeits may be easily distinguished by means of a file.

SECT. XIV.—ROCK CRYSTAL—TRANSPARENT QUARTZ.

6285. This stone is sometimes quite colourless, and beautifully transparent; it is also occasionally, though rarely, yellow like topaz; but it is softer than topaz, and of a different crystalline form in its natural state. The form in which quartz usually occurs is a six-sided prism, terminated by a six-sided pyramid, as *a*, *fig.* 815, or modified, as *b*, by having some of the angles truncated. Superb groups of crystals are brought from Dauphiné, and are sometimes seen upon the mantel-piece. These generally have the sides of the pyramids very unequal in size, as *c*. In quartz crystals, faint striæ may be seen, which are at right angles to the sides, and these serve to distinguish them from the crystals of other substances of nearly a similar form, but which have striæ parallel to the length of the sides. It is sometimes found of a light brown, called *smoky quartz*, as in the *cairngorum* stones used for seals, so called from being found on a hill of that name in Scotland. Small rolled pieces of rock crystal are frequently found in the sand of various places, as at Bagshot in the vicinity of London, which, from their scratching glass, as all rock crystal does, and taking a fine polish, are called *Bagshot diamonds*. Rock crystal, when colourless, is worked into many forms for different purposes, though seldom used in jewelry, except when it is coloured or set in foil. Large pieces are cut for the glasses of spectacles, called *pebble spectacles*, which are much less easily scratched than any glass.

Fig. 815



6286. The stone called *cat's eye* is a variety of rock crystal enclosing amianthus. It comes chiefly from Ceylon; its colour is light gray, and it presents a peculiar luminous appearance resembling the eye of the animal from whence it receives its name. A very rare variety of it is of a dark green. It is usually cut hemispherically.

SECT. XV.—AMETHYST.

6287. There is the same confusion respecting stones of this name as with others we have mentioned. The amethyst of modern mineralogists is merely a violet-coloured quartz or rock crystal; but what has been called Oriental amethyst among jewellers is a violet-coloured sapphire, which is a stone of great beauty and value. The colour of the common amethyst is purple, of various shades and degrees of intensity; those which are of the deepest purple are the most precious, but the depth of the tint varies much, being in some scarcely perceptible, when the stone is of scarcely any more value than rock crystal. Amethysts are found in many countries; but of late many have been brought from Brazil, and some of considerable size. They are much used in bracelets, seals, and similar ornaments.

SECT. XVI.—AVANTURINE.

6288. The avanturine is a beautiful and curious stone, appearing like a translucent crystal, having gold dust interspersed through it; but these sparkling grains consist of mica, and the stone itself consists of quartz. It is employed for snuffboxes and other larger ornaments. Fine specimens are rare. An artificial avanturine is made extremely beautiful: it is glass enclosing minute crystals of metallic copper.

The *sun-stone* is a beautiful variety of avanturine, having a bright, flame-like colour. It is used in jewelry, and is rare.

SECT. XVII.—OPAL.

6289. This stone is a very pure kind of flint, and differs from chalcedony chiefly in its lustre and colour; but the difference cannot easily be expressed in words. There is the *precious opal* and the common opal: the former exhibits a remarkable play of prismatic or iridescent colours—blue, red, and yellow, green, &c. These colours are sometimes, in fine specimens, intensely bright and beautiful; sometimes the stones exhibit only one colour. It is always cut hemispherically, and it is often full of flaws, which only adds to its beauty from increasing the vivacity of the colours. When fine, the precious opal is of great value; it is brittle, and softer than rock crystal. Common opal has not any iridescent play of colour, and is seldom employed in jewelry. The red opal is called *girasole*.

SECT. XVIII.—CHALCEDONY, AGATE, AND CARNELIAN.

6290. These stones are placed together because they are all varieties of the same thing. *Chalcedony* is a sort of very pure flint; but, instead of being perfectly clear and transparent, it is tinged, more or less, with a milky hue. When chalcedony has in it various curved parallel bands or stripes of a white or other colour, it is called *agate*.

Fortification agates are those which have zigzag parallel bands, generally of white and gray, having a distant resemblance to the plans of a modern fortification. They are frequently found in Scotland, particularly in Aberdeenshire, and hence are often called *Scotch pebbles*. They are also plentiful on the banks of the Rhine. In the centre of these agates there are sometimes rock crystals and amethysts. Sometimes, instead of these bands, there are minute metallic crystallizations resembling mosses, and which have been, though erroneously, supposed to be really vegetables; these are termed *moss agates*. Those are most valuable which resemble very closely some plant. *The onyx* is a variety where the bands of different colours are perfectly straight, the stone consisting of several flat layers, whereas in agates the layers are curved. Onyxes were much used by the ancients for making cameos; a figure was produced by cutting away a part of the white layer, the remaining part constituting the figure appearing as if laid upon the darker layer. *Carnelians* are nearly allied to chalcedonies, but are of a reddish colour. Agates, chalcedonies, and carnelians are very hard, take a fine polish, and are extensively used for ornaments, such as bracelets, seals, rings, and other purposes where large stones are admissible. They are likewise employed for making cups, handles for knives and forks, sword hilts, smelling-bottles, snuffboxes, &c. At Oberstein, near the Rhine, where these stones are found abundantly, they are cut and polished on a considerable scale by means of machinery moved by water, and the expense of manufacturing them is thus very moderate. The finest antique gems are engraved on stones of this class.

Sect. XIX.—Malachite.

6291. Malachite is sometimes used for necklaces and bracelets: it is of a fine green, and consists of carbonate of copper; it is opaque, and never cut in facets. It is not very valuable.

Sect. XX.—Jet.

6292. Jet is well known to be of a deep black, and is used for necklaces, chiefly worn in mourning. It is a kind of coal, or, rather, fossil wood, and costs little more than the expense of cutting; it is made into beads, snuffboxes, and other trinkets. Cannel coal is sometimes substituted for it, but this is very inferior.

Sect. XXI.—Amber.

6293. This is a well-known transparent mineral substance, of a yellowish colour, and is supposed to be a fossil resin. Its original situation is in beds of fossil wood called lignite, and it is sometimes procured by mining operations conducted expressly for this purpose; a great quantity is also collected on the seashores in various countries, having been washed out of its native beds by the action of the sea. The greatest abundance is met with on the shores of the Baltic, particularly in Pomerania. Fine amber is employed in making various ornaments and trinkets, as beads, heads of canes, mouthpieces for tobacco-pipes, &c., for which purpose it is easily cut, and takes a beautiful polish. The Oriental nations prize amber much more than the people of Europe. Occasionally insects are found in pieces of amber, which have been enclosed while it was in a fluid state. Amber may be dissolved by drying linseed oil, to form amber varnish.

Sect. XXII.—Pastes, or Imitations of the Gems.

6294. All the gems may be imitated in coloured glass, called *pastes*, so nearly as to deceive all except those who are much accustomed to the examination of real stones; but in hardness they are much inferior. To determine whether a substance be a diamond or a paste, apply a fine file to the girdle; paste is easily cut by the file, which can make no impression on a real diamond: also, the girdle of a real diamond will scratch any other stone, as the white topaz, which is not the case with pastes. Certain optical principles discovered by Dr. Brewster will enable those who understand them to discriminate real gems from artificial imitations, even if they are set, without unsetting the stones; but they are too complicated for this place.

The following receipts for imitation pastes are not given so much to teach the art of making them, which requires considerable skill, as to give general knowledge on the subject. It is scarcely necessary to mention that these pastes are to be cut by the lapidary.

6295. *To imitate gems in paste*, first, a perfectly colourless glass is prepared of silex, potash, borax, oxyde of lead, and sometimes arsenic. This is called *strass*, and to it various oxydes of metals are added to produce the desired colours.

For the colourless diamond: 3 ounces of rock crystal, 8 ounces of white-lead, 2 ounces of borax, ½ grain of manganese.

For the yellow diamond: to 1 ounce of strass, as above, add 24 grains of chloride of silver, or 10 grains of glass of antimony.

For the sapphire: to 24 ounces of strass add 2 drachms and 26 grains of the oxyde of cobalt.

For the Oriental ruby: to 16 ounces of strass add a mixture of 2 drachms and 48 grains of the precipitate of cassius, the same quantity of peroxide of iron, prepared by nitric acid, the same quantity of golden sulphuret of antimony, and of manganese calcined with nitre, and 2 ounces of rock crystal. Manganese alone, combined with the base in proper quantity, is said to give a ruby colour.

For the emerald: to 15 ounces of strass add 1 drachm of mountain carbonate of copper and 6 grains of glass of antimony; or, to 1 ounce of strass add 20 grains of glass of antimony and 3 grains of oxyde of cobalt.

For the topaz: to 10 lbs. of strass add 1½ oz. of calcined iron.

For the garnet: to 2 lbs. of strass add 2 lbs. of glass of antimony and 2 drachms of manganese.

Sect. XXIII.—Pearls.

6296. Pearls are precious, and form beautiful ornaments highly prized. They are calcareous bodies, of the same nature as mother-of-pearl, only purer, found in the inside of certain shells, particularly a large one, called the pearl oyster (Mytilus margaritiferus, Linn.). The history of pearls is so curious that it may demand a rather detailed account. The pearl shell, the inside lining of which constitutes the *mother-of-pearl*, is found only in warm climates. The shell sometimes grows to the size of seven or eight inches in diameter, is of a flattened and roundish shape, brown on the outside, but the inside entirely covered with mother-of-pearl. The pearls are found either loose in the body of the animal, or attached to the side of the shells, and they are supposed to be concretions of calcareous matter arising from some irregularity or disease in the animal. These shells are extremely abundant near the shores of some of the East India islands, and particularly Ceylon, where the chief pearl fisheries have been established. The shells are brought up by persons who have learned to dive for them to great depths. They descend to the bottom of the sea from five to ten fathoms in depth, assisted by a large stone, which they carry down with them; and, being furnished with a basket, they collect, with as much expedition as possible, such shells as happen to lie about the spot of their descent, continuing their search for about two minutes; when, according to a signal which they make to the boat to which their cord is attached, they again ascend with their treasure. Each diver will bring up as many as one hundred shells of various sizes, and some, from long habit, acquire the power of remaining under water for five or six minutes. It is not every shell that affords pearls: some contain only small ones of little value. The largest and roughest shells generally have pearls of the greatest number and largest size. Pearls are not cut and polished by the lapidary, but are worn in the state in which they are found, being only drilled for the purpose of stringing them, and are valued according to their size and beauty. The finest are of a clear white, and very translucent: those which have a tinge of yellow are less precious.

The price of pearls increases as the square of their weight; thus, the price of a pearl of one carat being settled at 8*s.*, to find the price of a pearl weighing six carats, first find the square of 6, viz., 36; which, multiplied by 8, gives 288*s.*, or £14 8*s.*; but the value of pearls depends also much upon their quality. It is a curious fact that the Chinese know how to force the shell-fish to produce pearls. They drill holes in the shell, and the animal, to secure itself from the depredations of marine insects that attack it, secretes the pearly juice to close up the aperture, and forms a pearl over it; but the most perfect pearls are those only which, being quite detached, are found globular in the body of the animal.

Though pearls are found of the largest size, greatest beauty, and most abundantly in the shell we have mentioned, yet they are not confined entirely to these: common oysters and muscles occasionally contain small pearls; and a fresh-water shell called a *unio*, or *pearl-muscle*, is particularly remarkable for the pearls it contains. It is found in various parts of Britain, but a regular pearl fishery of this shell has been long established on the River Conway in North Wales. The people there go out at low water and gather a number of these large muscles, which they boil, and beat the fish to a pulp; they then separate the pearls by mixing this with plenty of water. The pearls are not fine, and are small: they are of the kind called *seed pearl*, which are used for sewing on various parts of dress, and similar inferior purposes.

Pearls have been employed as ornaments from the earliest ages. In the time of Job they were accounted of great value. The story of Cleopatra drinking a valuable pearl dissolved in vinegar is well known, and may possibly have been true, since this substance, from its calcareous nature, is soluble in any acid. Before being drank the solution might have been diluted with water; and it would only have affected her as so much chalk in vinegar would have done.

6297. *Artificial pearls* were invented by a French bead-maker, of the name of Jacquin, about the time of Henry IV. This man observed that, on soaking and washing the scales of the fish called the bleak, a most beautiful silver-coloured powder was obtained; and it occurred to him that, by introducing this substance into the inside of finely blown glass bulbs, slightly tinged with opaline hues, a perfect imitation of real pearls might be made. The experiment succeeded, and these pearls came much into fashion for necklaces, ear-drops, &c., and continue still to be manufactured in Paris by the descendants of the original inventor, as well as in other parts of Europe, for various parts of dress. The silvery powder is fixed upon the inside of the thin glass globules by gum; and, if necessary, the hollow is filled up with wax. It is said that white bait affords a still more beautiful powder; and roach and dace have been tried, but they are inferior

So great was the demand formerly for these ornaments, that the price of a quart of fish scales was from one guinea to five. The price of real pearls has fallen much since this invention, which imitates them very exactly.

SECT. XXIV.—CORAL.

6298. This beautiful material, of a fine red colour, is the production of minute insects that inhabit the sea, and which consist of a fleshy substance, surrounding a solid, calcareous body, which is called the coral. The species of red coral, used for ornaments, in form resembles a small branched shrub, and is attached to rocks at the bottom of the sea, from whence it is taken by divers. The finest coral is found in the Mediterranean; it is procured on the coast of Provence, and there is a considerable manufactory of necklaces, crosses, and other ornaments of this substance at Marseilles.

SECT. XXV.—VARIOUS ORNAMENTS.

6299. *With respect to the various articles made by the jeweller as ornaments in dress*, or the infinite variety classed as trinkets, their description would far exceed the limits of this work. The most important of the former are *necklaces*, which are made of gold and gems, pearl, beads of stones or coloured glass, satin spar, amber, jet, or coral: *bracelets* are formed of gold, or velvet with clasps of gold, or copper gilded, plain, or set with stones, cameos, or other ornaments. The term *cameo* is applied to gems or stones worked in relievo; that is, where the objects represented are raised above the plane of the ground; but the stones on which the objects (generally figures) are cut consist of several layers of different colours, of which the most valuable are the Oriental onyx in black and white parallel layers, and the carnelian in brown and white. Some are cut on agates, and some stones of four layers of different colours. The ground is of one shade, and the relief of another. Antique cameos are valued at an immense price; and some modern Italian cameos are extremely fine; a single cameo of a good brooch size will sometimes cost twenty pounds. They are worked by a lathe and pointed instruments of steel, with diamond dust. A cheaper kind of cameos have been made lately, cut from large shells found on the African and Brazilian coasts, which have two layers, the ground being either a pale coffee colour or a deep reddish-orange; the latter is preferred. Copies from the antique are made in this manner, in Rome, of exquisite finish; and some very good are now done in this country. A cheap imitation of cameos is also made in glass enamel. *Earrings* are of gold, or copper gilded, plain, or with gems, or pebbles; the gold is made remarkably thin, for lightness, as well as on account of the expense. To these may be added *brooches* and ornamental pins, together with various ornaments for the headdress; also *rings*, which are plain hoops of gold, or with gems, as single stones, or in clusters varied in numerous ways, or with engraved stones, antique or modern. All those in gold are now so successfully imitated in gilded brass, that it is difficult to distinguish the latter from the precious metal.

BOOK XXII.

ECONOMY OF THE LAUNDRY.

6300. *Under the title of this branch of domestic economy, we propose to take an extensive view*, not only of the ordinary processes of what are termed "washing and getting up linen," but likewise of the theoretical principles upon which complete success depends, and likewise to give a short description of the nature and manufacture of the materials employed. In addition, we shall treat of the art of scouring, which, though it does not strictly belong to the ordinary business of the laundry, yet is intimately connected with it, and materially elucidates the modes of managing the restoration to a condition fit for use of the various articles of wearing apparel and furniture; confining ourselves, however, to such facts as are useful to be known in domestic economy, and omitting those which concern the manufacturer only.

6301. It is unnecessary to remark upon what is so well understood, the importance to health and comfort of cleanliness in dress and furniture; and custom now demands, not only that this shall be effected in the requisite degree, but that it shall be made apparent by the purity of their colour and appearance. We shall begin by explaining in a general way the rationale or theory of ordinary washing, or, in other words, the reasons why soap and other detergent substances are generally used.

CHAPTER I.

THEORY OF WASHING.

6302. The primitive mode of performing this operation, before *detersive* or cleansing substances were known, was, no doubt, washing clothes in simple water, and this method is still practised in many countries. The Hindoos carry their clothes to the

Ganges, where they undergo the necessary purification in water alone. But this requires much labour; and to remove with greater facility the discoloration of linen occasioned by being worn, which is partly of an oily nature, and therefore very difficult to destroy by water only, certain substances, called *detersive*, have been introduced, which assist in the process. Of these the principal one is soap; and it is requisite that we shall first take some notice of this material, and show in what manner it is so efficient.

6303. *It is well known that oil or grease is not soluble in, and will not unite with, water*; a greasy spot cannot be washed out completely by water only, unless such a degree of rubbing be employed as will injure the cloth in some degree. But if oil be united to an alkaline substance, the mixture of the two is soluble in water; hence, if the greasy spot be touched with an alkali, as potash or soda, the latter will unite with the grease or oil, which being then soluble in water, rubbing in that fluid, or washing, will cause it to disappear. If, then, soiled or greasy linen be washed in water containing potash or soda, the labour of cleansing is much less than with water alone, and the fabric, not being necessarily subjected to so much rubbing, suffers less wear.

6304. *All the ashes of burned vegetables contain more or less of the alkali called potash*; hence wood ashes was one of the most ancient detersive substances, and is still occasionally employed for that purpose. But alkalies, when used alone, have this inconvenience, that, although they are extremely effective, yet, if employed in too great a quantity, they are capable of corroding the clothes to be cleansed, and likewise of acting in the same manner on the hands. The difficulty of regulating properly their strength has led to the invention of soap, which consists of alkali already united to a certain proportion of oil or fat of some kind, by which its power of corrosion is so much diminished as not to destroy the texture of the fabric; and yet the alkali in the soap is capable of taking up a little more oil or grease, such as may be found in soiled linen; and that is likewise converted into soap. Now all soap being soluble in water, the whole of the impurities may be thus removed by rubbing the linen between the hands in that fluid. In fact, then, in employing soap for washing, we make more soap, though the newly-formed material is in very minute quantity, and does not become solid. Soap is not necessarily solid; if oil and any solution of alkali in water be mixed in a small vial and shaken together, liquid soap will be the result. Soap is made solid by certain processes of the manufacture, on account of the greater convenience in using it, than if it were in the liquid state. It will be easy to perceive, from this explanation, that the strongest soaps have the most alkali in their composition, since it is by the abundance of this ingredient that the cleansing effect is produced; and it will likewise be evident why soaps of different degrees of strength are suitable for different purposes. It may here be observed that there are other detersive substances besides soap, as wood ashes, and other things containing alkali. Various clays, and fullers' earth, have a similar effect, but produced in a different manner than it is from soap; by their absorbent quality they attract the oily particles from the cloth, and cause them to be more easily removed mechanically by rubbing in water, but no chemical union is thus formed, as in the case of soap.

CHAPTER II.

DESCRIPTION OF THE VARIOUS KINDS OF SOAP AND OTHER MATERIALS USED IN WASHING, AND OF THE INGREDIENTS OF WHICH THEY ARE MADE.

6305. It being useful that the nature of soap should be well understood by those who superintend the business of the wash-house, we shall first describe the alkalies employed in its composition, and which are occasionally used alone as detergents; and we shall afterward explain, in a general way, the manufacture of the soaps.

SECT. I.—POTASH AND PEARLASH, ETC.

6306. *We have stated that the ashes of burned vegetables* are often used for the same purposes as soap, in places where the latter substance is unknown or cannot be procured, and that they owe their detergent property to the same cause as soap, namely, the alkali which they contain. Their employment in this way was known to the ancient Egyptians, Greeks, and Germans. Pliny informs us that the Gauls were the inventors of soap made of tallow and wood ashes: a soap-boiler's shop has been discovered in Pompeii. In every vegetable there is a little alkali, though always in a state of combination, and some have a much larger proportion than others. When the rest of the vegetable substance has been dissipated in consequence of combustion, the alkali remains in the ashes, from which it has been termed *fixed* alkali, in opposition to ammonia, or the volatile alkali; it is also sometimes termed the vegetable alkali. Wood ashes are frequently employed in scouring paint that is very dirty, or for similar coarse purposes; but it must be observed that it should be employed cautiously, since, if too much be used, it would take off the paint itself. Good housewives understand the value of this material that comes from heating the brick oven in baking bread; it is also employed by them in scouring the wood-work of the kitchen, as floors, tables, &c.; likewise for cleaning the lids and insides of sauce-pans, for which it answers instead of potash. It is also very useful to soften hard water, and to make a *lye* for washing.

6307. *The simplest and rudest preparation of potash* is called *ash balls* in England, and *weed ash* in Ireland. It cannot be said to be properly an article of commerce, although a considerable quantity is annually made by the peasantry of both countries, and disposed of among the neighbouring farmers and bleachers. The vegetable from which, in England and Scotland, this impure alkali is produced is the common fern or brake (*Pteris aquilina*, Linn.). Many rough and heathy districts are entirely covered by this plant, which, when it has attained its full growth, about the middle of July, is cut down, and, after being half dried in the open air, is gathered into small heaps and kindled. The combustion proceeds slowly, being accompanied by a smothering smoke, and little or no flame, till the whole is reduced to a reddish-gray ash; this being carefully collected, is sprinkled with a little water, and then moulded by hand into balls three or four inches in diameter, which, when they have acquired a certain solidity by drying in the sun, are ready for sale. In Ireland, thistles, docks, and weeds of all kinds are mixed with the fern, and the ashes are disposed of in their loose, pulverulent state, without any farther preparation. One thousand parts of fern, cut in August, and thoroughly dried, afford thirty-six parts of ashes, from which are obtained about four parts of alkali. The common weeds do not give so much.

6308. *The crude potash of commerce, or black potash,* as it is also called, is universally procured from the combustion of wood, and therefore its preparation can be undertaken with success only in those uncleared countries where there are vast natural forests, and where, from the badness of the roads, and imperfection of water communication, the value of timber is no more than that of the labour required to fell it. The only districts of Europe in which any considerable quantity of potash is made are the mountainous forests of Germany, and the extensive woodland tracts of Poland and Russia. The British market, however, is principally supplied from the United States of North America, a country in which, from its rapid increase of population, there is a constant demand for cleared land for the purposes of agriculture, and, consequently, where timber is looked upon rather as an encumbrance than as contributing either to the beauty or value of the ground on which it stands.

6309. *The American method of making potash* is to pile up the wood, as soon as it is sufficiently dry to burn, in large heaps, and reduce it as quickly as possible to ashes; these ashes are then put into a wooden cistern, with a plug at the bottom of one of the sides, and a quantity of water sufficient to make a strong lixivium is added; after standing for an hour or two, the plug is withdrawn, and the water holding the potash in solution runs out, leaving the earthy part still impregnated with some alkali in the cistern. This solution is then evaporated to dryness in iron pans or pots (whence the name potash), and hastily fused into compact reddish masses of semi-caustic potash, in which state it is fit for the market.

6310. *The common potash* of the north of Europe is the impurest of all, containing nearly one half its weight of earth, and is thus prepared: A large pit is dug, into which is thrown burning brands and the smaller extremities of the branches, and when the whole is well kindled, the pit is filled up with logs and other large pieces, which at length, though very slowly, are reduced to ashes. The coarser part of the ashes is then separated by sifting from the finer; all the alkali that it contains is procured by lixiviation, and this liquor is mixed with the remainder of the ashes, and wrought into a paste. A pile is then built of wood, the interstices of which are filled with this paste, which being set fire to, the whole is reduced to ashes. This process is repeated several times, till the ashes begin to clot and become hard; the most compact pieces being then selected, are packed up for sale, without any farther preparation; the rest are lixiviated and boiled down to dryness in the usual manner. All the potash we have from Russia, Sweden, and Dantzic is made in this manner. The Russian is the best of these; it is brought to us in large lumps, very hard and black, incrusted here and there with a white salt. When dissolved in warm water, it deposites a sediment of a blackish-gray colour, and the lixivium has a sulphurous smell, bitter taste, and a dark green colour.

6311. *Potash may be made from potato leaves and stalks* thus: cut off the stalks when the leaves begin to fall, spread them out and dry them thoroughly in the sun. Dig a hole about four feet in diameter and one foot deep in the ground, in a dry place; make a fire with the dried stalks in this pit, and continue feeding the fire with them till the whole is consumed; put the ashes into a vessel with water over the fire, and boil them; the potash being soluble, will be extracted by the water, and form a lye; pour off this lye, and evaporate the water by boiling; in the bottom of the vessel, when the water is gone, the potash in an impure state will remain as a grayish substance. To destroy the impurities, calcine it in an iron pot, to burn off all the charcoal and other substances mixed with it. The potash will now remain in the usual state of purity of common potash. Potato leaves give a larger quantity of alkali than most vegetables.

6312. *A very simple but rude method of effecting the evaporation of the water from the lye* is practised in some places. They place a tubful of the lye near the clean hearth of a chimney, in which they dip a handful of loose straw; the straw, thus containing a quantity of the lye, they carry as quickly as they can to a blazing fire made upon the hearth, which first dries and then consumes the straw to ashes, thus evaporating all the water from the alkali in the lye. They then prepare, in the same manner, another parcel of straw, by dipping it in the lye, and consume it as the other; and this they repeat till all their lye is expended. By this means the ashes of the straw, that of the fuel, and the alkali of the lye are left on the hearth mixed together, and they concrete the whole into a hard, solid cake, of a greenish-black colour, which they scrape off and sell for potash, but it is unfit for many purposes, and not above half the value of the foreign.

6313. *The proportion of ashes afforded by different vegetables, and that of alkali by each vegetable*, has been accurately attended to, on account of its great importance in the arts. Kirwan gives the following statement:

	lbs. of ashes.		lbs. of alkali.		lbs. of ashes.		lbs. of alkali
Stalks of Turkey wheat, or maize	88·6	and	17·5	Oak	13·5	and	1·5
Sunflowers	57·2	—	20	Aspen	12·2	—	0·74
Vine branches	34	—	5·5	Beech	5·8	—	1·27
Common nettle	10·6	—	25	Fir	3·4	—	0·45
Box	29	—	2·26	Fern, in August	36·46	—	4·25
Sallow	28	—	2·85	Wormwood	27·44	—	73
Elm	23·5	—	3·9	Fumitory	219	—	79

From an inspection of this table, it appears that, in general, weeds or succulent herbaceous plants yield a much greater proportion, both of ashes and alkali, than the shrubby and ligneous ones; but it must be observed that, as all the plants were reduced to a state of dryness before they were weighed, it required a much greater quantity of the former.

Kirwan makes the following remarks upon the processes for extracting potash from plants. The weeds should be cut just before they seed, then spread, well dried, and gathered clean. They should be burned within doors, on a grate with a brisk fire, and the ashes laid in a chest as fast as they are produced. Any charcoal found mixed should be picked out. They should be lixiviated with twelve times their weight of boiling water, and the lye thus formed is to be evaporated in iron pans, from which the term potash is derived.

6314. *Among other methods of procuring potash, one deserves to be noticed*, discovered by Mr. Birch, a bleacher at Manchester. He evaporated a large quantity of dunghill water to the consistence of treacle, and then burned the residuum in an oven, and from this he procured potash, which he employed in the operation of bucking. From a quantity of muck-water equal to twenty-four pipes full, the quantity of ashes made was 9 cwt. 1 qr. 12 lbs., valued at two guineas per cwt. In the manufacture of the potash in this manner, there was a profit of £15 4*s*., allowing for all the expenses. This alkali appears to have been formed by the process of putrefaction.

6315. *Pearlash* is a much purer state of the alkali, prepared from the crude potash. For this purpose, the potash is broken down into moderately small pieces, and is spread upon the floor of a reverberatory furnace, where it is kept hot, but not melted, for an hour or two, stirring it occasionally with an iron rake, until all the carbonaceous and colouring particles are burned out, and there remains behind a dry, porous, and considerably caustic salt, extremely deliquescent, which, from its bluish-white colour, is called *pearlash*.

6316. *Both potash and pearlash differ considerably in their strength*, as in the quantity of alkali which they contain: a circumstance of considerable importance to the manufacturer, who finds great difficulty, in consequence, of fixing accurately the value of any quantity. An analysis of any one piece would not give that of the whole parcel, as the proportion of the impurities is quite irregular. Mr. Kirwan gives an analysis of Dantzic pearlash, which may serve at least to give a general idea: Pure potash, 60·3; carbonic acid, 22·4; water, 7·2; sulphate of potash, 8·7; muriate of potash, 0·7; earth, 0·7 = 100·0.

SECT. II.—SODA.

6317. *Soda* was formerly called the *mineral* or *fossil* alkali, because it was dug out of the earth. The use of soda was familiarly known to the ancients, and abundance of it in a native state, called *natron*, was found in Egypt. It is now known to occur likewise in the vegetable kingdom, and the base of it, called sodium, is one of the components of common salt; indeed, a great part of the soda that is employed in this country is obtained from the latter source. While the vegetables that grow in common soil yield potash, those which flourish in salt-water, or on the seashore, or wherever the soil is impregnated with salt, yield soda by incineration, this alkali having existed in the plants when living, in consequence of their situation

There are two substances manufactured from which vegetable soda is procured, *barilla* and *kelp*.

6318. *Barilla is the richest in soda*, and comes chiefly from Alicant in Spain, from plants of the genera Salsola and Salicornia, which are cultivated for that purpose very extensively in the *huerta* of Murcia, and other places on the eastern coasts of Spain. The plants are sown in light, low soils, that are embanked on the side next the sea, and furnished with flood-gates, by which the salt-water may be admitted occasionally. In autumn, when the seeds are ripe, the crop is cut down and dried; the seeds are rubbed out, and the rest of the plant is burned in very simple furnaces, the temperature of which is just high enough to cause the ashes to enter into a state of semi-fusion, and to concrete into compact cellular masses. The barilla is of a grayish-blue or brownish colour, covered over with a saline efflorescence when exposed for some time to the air; it is exceedingly hard, and of a pungent alkaline taste. Barilla is also manufactured in Sicily and Teneriffe, but it is inferior to that of Alicant and Carthagena. The best barilla sometimes contains 20 per cent. of soda.

6319. *Kelp is much more impure than barilla*, containing only from two and a half to five per cent. of soda. It is made from what is vulgarly called sea-weed, chiefly of those leafy marine plants called *fuci*, which grow on the rocks in the sea, between the high and low water mark. These plants are cut down in the summer season, dried, and burned in shallow pits made in the ground, and, when care is used, in furnaces for the purpose. The combustion is kept up by throwing on a little at a time of the dried plants; and when a certain quantity has been consumed, the ashes are stirred about with an iron rake till the whole, in partly a liquid or pasty state, concretes together. When cool, the mass is broken up, and constitutes the kelp. Well-made kelp is of a bluish-gray colour, is rather cellular, and contains a good deal of charcoal from the half-consumed plants; its taste is alkaline and salt. It is rather tough, but not so hard as barilla. Kelp is much employed where soda is wanted in making glass and soap; also in bleaching, &c. Some years back a great deal of kelp was manufactured on the British shores, and formed a considerable source of wealth to the proprietors, but at present its price has very much decreased, from the great superiority of barilla and the mode of obtaining soda from salt.

6320. *The soda is extracted from barilla or kelp* by dissolving them with boiling water and filtering the solution, which is thus evaporated; by this crystals of carbonate of soda are obtained, from three to five ounces being procured from 1 lb. of barilla.

It must be observed that, though the carbonate of soda procured in this manner is sufficiently pure for many purposes in the arts, as in bleaching and washing, making soap, glass, &c., it is not so for the purposes of medicine, as it always contains more or less of the sulphate and chloride of potassium and sodium, from which it cannot be easily separated. The purest carbonate, used for pharmaceutical purposes, is made from sulphate of soda procured from a different source.

6321. *Large quantities of carbonate of soda are now made by decomposing common sea salt*, which consists of chlorine and sodium, and is called, chemically, chloride of sodium (formerly, muriate of soda). By applying sulphuric acid to this salt, the sodium is changed into soda, quits the chlorine to join the sulphuric acid, and thus sulphate of soda is obtained. This, by other processes, is decomposed, and the soda liberated, and procured in a free state; which is a modern discovery, in consequence of which soda is not a third of the price it was formerly.

6322. *The alkalies potash and soda, when in a state of perfect purity*, and not combined with any other substance, are of a highly caustic nature, that is, they powerfully corrode animal and vegetable substances; hence, although they would readily unite with oil or grease, so as to make it soluble in water, yet they would entirely destroy the texture of cloth, linen, or any similar substance, and therefore could not be used as detergents in that state.

6323. *But when these alkalies are united with carbonic acid*, and are thus converted into *carbonates*, they are rendered much less caustic, and, although they will still render grease soluble in water, yet they become so mild that they will no longer act powerfully upon the texture of cloth, and may then, in moderate quantity, be used with safety as detergents. Hence it is that in this state alone they are employed in washing, bleaching, scouring, &c.

6324. *Carbonate of soda is far preferable to carbonate of potash* for these purposes, because it is much less acrid, and is not so apt to injure the texture of linen goods as potash. It is, accordingly, much more extensively employed, particularly since means have been discovered of preparing it so cheap as to supersede pearlash almost entirely.

CHAPTER III.

ON SOAP.

6325. *The most usual and the most convenient mode of employing the alkali for the purposes of washing is when made into soap*, the action of which has been already explained. *The various kinds of soap* are made of one or other of the fixed alkalies, potash or soda, combined with fat or oil. We explained above that it is the alkali which gives to soap its detergent quality, and which renders it soluble in water. The tallow serves to moderate the sharpness of the alkali, and to prevent its injuring the hands of those who use it.

6326. *There are two principal varieties of soap, hard and soft.* The former is made of soda and tallow or oil, and the latter of potash and similar oily matters. When tallow and soda alone are employed, the soap is white; hence it is usually termed *white* soap; but, to lower the price, in forming *yellow* hard soap, a considerable portion of resin or palm oil is mixed with the tallow. When potash is mixed with tallow or oil, the resulting soap does not assume a solid form, and its consistence is never greater than that of hog's lard: this makes the *soft soap*, the detergent properties of which are nearly the same as those of hard soap, but it is not so convenient for general use.

6327. *Common hard white soap is made in the following manner:* The alkali employed is soda, procured from barilla or kelp. In order to cause the alkali to unite with the fat, oil, or tallow, to make a soap, it is necessary that the former should be in a caustic state instead of that of a carbonate, and to this end it must be deprived of its carbonic acid. To effect this, the barilla or kelp is pounded, and mixed with one fifth of its weight of fresh quicklime in a large vat, and some water is then sprinkled over it to slack the lime, which then falls into powder, and the alkali is mixed with it by means of a shovel; the quicklime then attracts the carbonic acid from the alkali, which is consequently left in a caustic state. After standing for several hours, till this is completed, some water being added, the liquid, containing the caustic soda in solution, and now termed a lye, is drawn off. More water is then put on the alkali, and is drawn off as a secondary lye. The tallow or oil is next put into a boiler, and, when it is quite melted, the lye is gradually added, and the mixture is kept constantly stirred. The alkali and oil soon begin to unite into a milky fluid, and as more lye is added, this liquid thickens. In about thirty hours it is found that the consistence is sufficient, and then a quantity of common salt is added, to cause the water to separate from the soap and to harden the latter, which floats at the top. The fire is now withdrawn, and the mass left to cool. The watery part found at the bottom is removed by a pump. When this has been effected, the fire is rekindled, and the soap is remelted, and agitated with wooden poles, until it has acquired the consistence proper for lading into square moulds, in which the soap, after it has set and become solid, is cut into the proper shapes by a piece of brass wire. It is to be observed that, of late, the boiling is often performed by means of steam. Manufacturers vary a little in the details of their process and in the proportions of their materials. The lime which was added was only for the purpose of robbing the alkali of its carbonic acid, and therefore does not enter into the composition of the soap. In the south of Europe, where the olive grows, olive oil is used for making soap instead of tallow.

The soap itself is a compound of pure alkali with oil, fat, or tallow, and a portion of water. The very hard soap, made with all soda, is not the most convenient for use; it is neither so fit for washing the hands, nor so easily reducible to the pulpy state for the different manufactures in which it is employed.

The hard white soap, made in some manufactories of tallow, with a mixture of soda and potash, is much esteemed. It appears that soap cannot be made of a great variety of proportions in the ingredients, but that the proportions are what are termed definite, that is, fixed by natural laws; so that in 100 parts of hard soap there are 60·94 parts of oil, 8·56 of soda, and 30·5 of water. If the alkali is potash instead of soda, then the proportions are 58·4 parts of oil, 12·3 of potash, and 29·3 of water; so that, in general, soap contains from 8 to 12 per cent. of alkali, 58 of oil, and about 30 per cent. of water. Soaps, particularly the hard, are frequently reduced in value by the fraudulent practice of keeping them wet; by a nefarious management, they are made to contain 60 per cent. instead of 30 of water. In this case they are found to lose weight rapidly by exposure to the air, a discovery often too late.

6328. *Yellow hard Soap.*—This soap is formed of similar proportions of soda and tallow as the last, but it also contains resin, and sometimes palm oil, which is added to correct the smell of the resin. In boiling the yellow soap, the resin, oil, and tallow are put into the boiler first, and the lye added when these are melted. The boiling likewise continues a longer time, sometimes three weeks. The rest of the management is nearly the same as in the white soap. The resin makes the soap more detersive, and enables the manufacturer to sell it cheaper. Sometimes a portion of "kitchen stuff" is used with the tallow, but this is not so good.

6329. *Soft or mottled Soap.*—This differs in its composition from the hard in containing all potash instead of soda; and in this country whale or other fish oil is used with the potash, which makes a mass somewhat transparent, and of a yellow colour. Our soft soap is always interspersed with white specks, giving the whole a resemblance to the inside of a fig; these spots are produced by the addition of a little tallow; and they do not improve the soap, but habit renders them indispensable in the trade. There is no material difference in the process of boiling it from that of the other soaps. Soft soap was the first kind invented by the Germans, who made it of tallow and wood ashes, the latter containing potash.

Soft soap made of colourless fat, such as tallow, is a white, unctuous substance, about the consistency of lard. If the fat be coloured, the soap partakes of the colour; and on the Continent it is the custom sometimes to add colouring ingredients.

6330. *A very simple method of making soft soap is used in Canada* where wood ashes are abundant. The wood ashes are put into a barrel, and a lye is made by pouring water upon them; this lye is then poured off, and four or five pounds of grease are added to it: any refuse grease may be collected for the purpose, as pot skimmings, rinds of bacon, scraps of suet, &c. The barrel with its contents, well stirred together, may then be placed in the yard, exposed to the sun and air. In course of time the lye and grease become incorporated. If any fat swims upon the surface, it is a proof that there is not lye enough, and some more must be added; if the mixture does not thicken, then soap does not form, and more fat must be added. Upon adjusting the proportions of these the thickening of the soap depends. This mode of making the soap will not be found very certain, if a good article be expected; but what is so made will do very well for the ordinary purposes of washing. In this mode boiling is not employed.

In making lye for soap of wood ashes, care should be taken to use none but the ashes of the hard woods, as oak, ash, maple, beech, &c. The resinous trees, as the pine and fir tribe, are bad for the purpose, and the lye will not unite with the fat.

6331. *Hard soap is also made* by making first a soft soap by tallow and a lye of potash, rendered caustic by quicklime; to this is added common salt (muriate of soda) or kelp lye, which contains both soda and muriate of soda; the muriatic acid of the common salt goes to the potash, forming muriate of potash, which is drawn off in the waste or spent lye; while the soda unites with the fat, and forms hard soap. Soft soap is, therefore, easily converted into hard soap by the addition of common salt in the manufacture.

6332. *Soap is the better for being kept some time;* indeed, it should never be used when newly made, but, for economy, should lay by to harden slowly; if dried too fast, it will crack.

6333. *A mixture of pipe clay with soap* has been long employed in various parts of the Continent as an economical substance for washing, producing, it is said, by its mechanical action, a saving of part of the soap. *Lately a soap has been made here called silica soap*, by combining fat or oil with silicate of potash, the latter being produced by boiling flints calcined and ground in caustic lye. But this is not, as some suppose, an increase of the actual soap made by means of the flints, but is to be considered rather as flint powder mixed with soap; accordingly, it is a harsh kind of soap; its superior detergent quality, if it possess any, being owing only to the mechanical agency of the flint powder, in the same way as the pipe clay above mentioned; and it would probably prove very destructive to linen washed with it. It ought, indeed, to be understood that the mixture of silica or clay with soap is an adulteration, and not an improved kind, neither of these materials combining with the alkali, so as to produce soap. It has been stated in a report to the commissioners of excise, that though a pound of this adulterated soap may cost only 4¾*d.*, while an equal quantity of good soap will cost 6*d.*, yet that 4 lbs. of the latter will go as far as 5 lbs. of the former.

6334. *Ball soap*, commonly used in the north, is made from lees, with ashes and tallow. The lees are put into the copper, and boiled till the watery part is quite gone, and there remains nothing in the copper but a sort of saline matter (the very strength or essence of the lye); to this the tallow is put, and the copper is kept boiling and stirring for above half an hour, in which time the soap is made; and then it is put out of the copper into tubs or baskets, with sheets in them, and immediately, while soft, made into balls. It requires nearly twenty-four hours to boil away the watery part of the lees.

6335. *The alkaline lixivia, or soap lees*, that is, the solutions of alkali alone, are capable of dissolving oils more effectually than soap, and are sometimes employed for the same purposes; but, as we have stated, from their great causticity, they are capable of destroying many substances to which they might be applied, as silk, wool, &c., whereas soap cleanses from oil almost as effectually as pure alkali, without any such danger. Those soaps which contain the largest portion of alkali, being the strongest or most detersive, act likewise most upon the skin, which is the property of the common brown hard soap, and still more of the soft soap used in the common business of the wash-house. The fine hard white soaps are preferred for the toilet.

6336. *The manufacture of soap in London first began* in 1524, before which time this city was served with white soap from foreign countries; and the gray soap, speckled with white, from Bristol, sold for a penny a pound, and black soap cost only a halfpenny the pound.

6337. *Soap-suds*, too often thrown away, even from large mills and manufactories, it is useful to know, are found highly beneficial as manures, particularly when mixed up and blended into composts with other materials. The farmers in some places understand this, and collect them, paying from 6*d.* to 1*s.* per hogshead; they are found valuable for putting upon meadows. Where there is much washing, it would be well to collect and preserve this liquid manure in a tank. What is called *soapers' waste*, in the soap manufactories, is particularly important as manure.

6338. *Potatoes have been tried with some success for washing instead of soap.* The first account we have of this method is from Cadet de Vaux, a French chemist; and a process verbal was published by M. Hericard de Thury of experiments made in the hospitals in Paris. The linen was put to soak for half an hour; then it was slightly washed, and put into a vessel with warm water; each article was then rubbed on both sides with potatoes three parts cooked, in the same manner as if they were pieces of soap. When the whole had been thus well rubbed, it was put into the copper and boiled for half an hour; after which it was taken out again, rubbed, beat, and turned and pressed in all directions, and again plunged for some minutes in warm water, and afterward rinsed. The linen is said to have been made perfectly white, while the expense and labour were less than by the ordinary method. A modification of this process is used here by the scourers. See "Scouring," Chap. XI., Book XXII.

6339. *A plant called soap wort,* belonging to a family named by botanists *Saponaria,* and which contains a good deal of alkali, is used in some places instead of soap, by making a decoction of the leaves and flowers to wash stuffs.

6340. *Rice-water is employed in India* for washing cottons and muslins.

CHAPTER IV.

WATER FOR WASHING.

6341. *The quality of water used for washing* is a circumstance of the first importance in the process. In Chap. I., Book VIII., "On Water," we explained the nature and properties of the different kinds of this fluid, as obtained from various sources, as well as the difference between hard and soft water. To this we must refer our readers. The softest waters are the fittest for washing, simply because they are the purest, containing no salts capable of decomposing the soap and destroying its action.

6342. *When water is hard,* it is owing to its containing earthy salts, generally either carbonate of lime or sulphate of lime, the acids of which seize the alkali of the soap, which is united to the oil only by a weak affinity. If the cause of hardness be carbonate of lime dissolved in the water, simple boiling for a considerable time corrects it by driving off the carbonic acid in the form of gas, when the lime falls to the bottom, leaving the water soft, which may then be poured off and used for washing; or the addition of quicklime may effect it, as has been stated. But when the hardness proceeds from sulphate of lime, or lime united to the sulphuric acid, which is the most frequent case, boiling has no effect, because the sulphuric acid cannot be driven off in this manner. It is then necessary to decompose the sulphate of lime by putting into the water some common soda, or potash, or pearlash, as may be most convenient. Even wood ashes will answer the purpose if no better material is to be had, because, as we have shown, they contain potash. As spring water and well water are very frequently hard, the addition of soda to such water is a very common and a very useful practice.

Even exposing spring water that is hard from containing carbonate of lime only, for some time in a cistern, will correct it to a considerable degree, because the carbonic acid will fly off in time, leaving the lime to fall down.

If the water be impregnated with the minutest portion of iron in any state, this will communicate a yellowish tint to the linen, which it will be very difficult to get rid of; and such water will therefore be very unfit for washing.

6343. *Sea water is not fit, in its natural state, for washing linen,* because the salt in the water decomposes the soap, and prevents its action. To remedy this, add soda to the sea water, the effect of which will be, first, that the water will become turbid, and a precipitation of earths will take place. When, by adding sufficient soda, all the white precipitation has subsided, the water will be found soft and fit for washing. The explanation of this effect is as follows: Sea water contains a certain proportion of hydrochloride of calcium and hydrochloride of magnesium, as well as hydrochloride of sodium. As hydrochloric acid has a stronger affinity for soda than for lime or magnesia, it will unite with the soda which has been added and leave the earths, which therefore fall down or are precipitated. The water is now salter than before; but more soda must be added than is sufficient to form sodium, or saturate the hydrochloric acid; then the latter is rendered ineffective, being unable to decompose soap. Sea water, therefore, with this excess of soda, acts nearly as fresh water. A kind of soap is now made and sold for washing in sea water.

CHAPTER V.

ON STARCH.

6344. *Starch is one of the essential articles in the business of the laundry,* and though it can always be purchased of good quality in Britain, yet, in uniformity with our plan, we shall describe its manufacture or mode of production, as well as its properties and the manner of using it.

In treating of the principles of vegetables, Book VII., Chap. VII., we showed that starch is ready formed in certain plants, being one of their proximate principles; and all that the manufacturer has to do is to separate it from the other constituents. It will be proper here to enumerate again the properties of starch, as far as they are concerned with its use in the laundry.

6345. *Starch consists* of extremely minute oval-shaped grains, much too small to be distinguished by the unassisted eye, but which may be plainly seen by a good microscope. When pure, the mass is of a brilliant snow-white, and without any taste. It will not dissolve in water either cold or below 160°; but in water between 160° and 180° it forms an imperfect solution, thickening into a gelatinous or jelly-like consistence, in which state it is employed by the laundress.

6346. *Although all vegetables contain more or less of starch,* yet some possess a much larger proportion than others, and are therefore fittest for the production of this substance. In treating of the constituents of vegetables in general, we pointed out those from which it is extracted in the greatest quantity.

6347. The starch made with us for the use of the laundry is procured from two vegetables only, wheat and potatoes.

6348. *Starch from wheat* is manufactured as follows: It is not necessary that the grain should be ground into flour. The entire corn, well cleaned, is soaked in cold water until the husk easily separates; and the grains, having become quite soft, give out a milky fluid by pressure. The wheat is then taken out of the water, put into coarse linen sacks, and transferred to another vat with water, where it is subjected to pressure. The milky juice exudes and mixes with the water; and when the whole has been pressed out, the sacks and their contents are removed. On the whole standing still, the starch precipitates to the bottom, but will not be quite pure, as it holds a small quantity of the gluten of the wheat, though the greatest part of this remains in the sacks. In order to free the starch from this gluten, the whole is suffered to stand still for about ten days in summer, and fifteen days in winter. During this time a fermentation takes place, owing to the following cause. Dissolved in the water, there is a little saccharine mucilage, which is also one of the principles of the wheat: it is this that begins the fermentation, which is of the acetous kind, and, in consequence, a small quantity of sour liquor or vinegar is produced. This acetous acid acts upon the gluten and dissolves it, but not the starch; which is, therefore, freed from the other matters. After this fermentation has continued long enough, the starch subsides to the bottom quite pure, and the water is let off.

The starch, well washed by several waters, is dried by a gentle heat, first in the open air and afterward in an oven, during which it cracks into those irregularly columnar forms in which it appears when sold, and which have had a slight tinge of blue given to them in the manufactory to overcome any tendency to a yellow colour which they might possess. Very fine starch is imported from Poland and from France, usually considered to be superior to the English, which is not unfrequently adulterated.

6349. *Lately a very superior kind of starch has been made from rice,* which, it is said, has some advantages over wheat starch, particularly that of not causing the linen to stick to the iron in ironing.

6350. *Starch made from potatoes* is not equal to that from wheat, but is found useful upon occasion.

6351. *To make potato starch,* procure some of the best mealy potatoes and a common bread grater. Wash the potatoes, grate them into a pan or tub of clean water, and stir the pulpy mass well about in the water: after a little time the thickest part will subside to the bottom; then pour off the white water, keeping back all the pulp. Add some more water to the pulp, stir again, and pour the whitened water off as before. Repeat this process with more water as long as the water comes off whitish. Let the whitened water that was poured off remain at rest some time, and the white part will settle to the bottom, leaving the water quite clear. This subsided matter is the starch. Pour off the water, and dry the starch in the sun; it will generally weigh one fifth of the best potatoes. Here fermentation is not necessary, because potatoes have no gluten like wheat; the starch is pure at once. This kind of starch, though it answers for some domestic purposes nearly as well as wheat starch, is sensibly different; it sets or becomes a jelly with a degree of heat somewhat lower than wheat starch, and is more apt to become moist in damp weather; but it is said to go rather farther than common starch, a smaller quantity being sufficient for the purpose of the laundress. It is, however, but little used.

6352. *A tolerable starch has been made from horse-chestnuts* by the following process, although it is now out of use: The prickly husk of the chestnut being removed, all the coloured skin must be pared off, and the chestnuts rasped, bruised, or ground very fine in water and well stirred. The white water is then poured off and suffered to stand till the starch settles to the bottom.. This, if not quite white, is again mixed with water, and passed through a flannel tamis or muslin sieve, and left to subside as before. By repeating this process as is found necessary, the starch is obtained, and is afterward dried for use. A patent was granted in 1796 to Lord W. Murray for this process.

6353. *Powder and stone blue,* used in washing linen, is a kind of coarse smalt, prepared abroad, and brought here either in the state of powder or lumps. *Smalt* is a glass coloured blue by zaffre or oxyde of cobalt, and reduced to a fine powder. The use of blue to the laundress is to mix with starch to destroy the yellow tint that the latter is apt to impart; and in general, when the linen is ill-coloured, a little blue neutralizes the yellow-brown, and makes it appear to be more white.

CHAPTER VI.

PRACTICE OF WASHING, DRYING, IRONING, ETC.

SECT. I.—WASHING.

6354. *Some directions for the management of linen previously to its being washed* may be useful; and we may, at the same time, observe that, though the term linen strictly means only cloth made from flax, yet, on this subject, it is usual to apply it in a general way to express most of the articles, whether linen or cotton, which are submitted to the various processes of the laundry.

6355. *Soiled or foul linen ought not to remain long unwashed,* as the dirt is then more difficult to be removed. Some families wash only once a month, but once a fortnight would be better; in the mean time the various articles, as they are soiled, should be put aside till washing day (for which Tuesday is usually chosen) with method, instead of being thrown together in a heap. This will save a great deal of trouble in sorting and keeping account of them. When they are numerous, each kind of article should be put into a separate division, bag, or place, by itself; and, to be very exact, it would be easy to make an entry on a tally or book of the number of things put by. What has been used in the kitchen and other offices should be kept separate, being generally greasy, or otherwise very foul; and, as nothing is more unwholesome, or more apt to injure the air of a house than collections of foul towels or rags of any kind, these should, if possible, be kept in some outhouse. Silk stockings, blonde, lace, dresses, and various nice articles that require particular skill in cleaning, come within the province of the lady's-maid. Washing blankets and bed furniture does not take place above once a year.

6356. *With respect to the persons engaged to wash,* bodily health and strength are first-rate qualities; yet general intelligence is also very desirable, since much, after all, must be left to their discretion; and it would be well that they should be of such a disposition that they will attend to any directions given to them, although these may vary somewhat from their usual practice; and that they should be free from that obstinacy and tenaciousness of old modes, which become very troublesome when improvements are introduced.

6357. *Spots of grease or gravy on table-linen or napkins* should be washed out with soap and water as soon as the cloths are withdrawn, otherwise they are sometimes difficult to remove after the linen has lain long by; and stains from ink, wine, or fruits should likewise be taken out. The manner of doing this will be pointed out.

6358. *The usual process of washing has been thus given to us by an intelligent laundress:* "On the Monday, the day previous to washing day, the business of the laundress begins by collecting all the various articles to be washed, and entering them in the washing book; in preparing the coppers, filling them with water, laying the fuel ready to be kindled, &c.

"*Soaking and Washing.*—On the afternoon previous to washing day, the linen should be put to soak in a weak lye of lukewarm water, having a little soda put into it; but first it must be well soaped in such parts as are the most soiled; and this operation should be performed with care, as it contributes much to the facility of the washing by loosening the dirt, and thus saving labour as well as the wear of the linen. For soaping the worst parts, soft soap will be found most economical. No more warm water should be used than is just sufficient to cover the linen when pressed down in it, that the strength of the soap may not be reduced. When washing is required to be done in the best manner, it is the custom with some laundresses, besides rubbing the worst parts with soap, to run the whole through water that has had soap dissolved in it by cutting it in slices, by which every part of the linen is sure to be penetrated by the soap, and no part can be missed. Care must be taken that the first washing is not done with water too warm, or it will set in the dirt."

6359. *Some have recommended to mix lime-water with the water in which the linen is soaked,* with the view of saving soap and softening the water. The lime-water is made by mixing a pound of quicklime in ten gallons of water, and letting this stand for twenty-four hours: the clear water is then decanted off from the lime. This practice undoubtedly has the desired effect of rendering less labour necessary in the subsequent washing, and does save soap; but, when used too freely, there is danger of the linen being injured, owing to the causticity of the lime. Indeed, complaints have been made that household linen has been found to be destroyed in a few weeks after coming home from laundresses who have been in the habit of using lime.

6360. *It is unnecessary to say much respecting the manual operation of washing,* since that is well known. Those who attempt it for the first time generally rub the linen against the skin, by which the latter is frayed, and sometimes rubbed off; whereas practised washerwomen take care to hold the linen so as to rub one part of its surface against another part, and, of course, not against the hand, otherwise they could not continue their work for the length of time which they do. We refer the reader to what we have said on the theory of washing for the *rationale* of the effect of the soap and friction in removing the dirt, and restoring the linen to its pristine purity.

To save soap, it is usual now to put some soda into the lukewarm water to render it soft: the quantity must be determined by experience; if too much be used it will exhibit its effects upon the hands of the operators. Soda is more particularly useful when the water is at all hard, and will not make a lather: the best way of using it is to have a jug at hand with the soda dissolved in water, and to add a little at a time as the lather becomes weak. Careless washers leave their soap in the water, where it dissolves, and is wasted unnecessarily. It is a good plan to provide little wooden bowls with perforated bottoms, placed on saucers, to put the soap into when it is not used: wood is the best, as not being liable to be broken.

"*After the linen is well washed with plenty of lukewarm water the first time*, it is to be put into a fresh quantity of water as hot as the hand can easily bear, and washed in this again, examining the whole carefully to see that no part has been missed; any such must be again washed until the whole is quite clean.

"*The next operation after washing is boiling the clothes*, in order to produce a good colour, and to remove entirely the soap or other detergent matters that have been used, which, if left in, would occasion a disagreeable smell. In the water used for boiling, a little soda is sometimes added in the proportion of half a tea-spoonful to a gallon of water. Some enclose the linen in a bag before it is put into the copper to boil, in order to guard it effectually from the scum of the water, which is apt to attach itself. After being boiled for about twenty minutes or half an hour, the linen is taken out, well rinsed in abundance of clean hot water, and afterward in clean cold water which has a sufficient quantity of blue to give the proper tinge. It is then taken out and wrung dry; and care must be taken that the texture is not injured by the operation. It is then ready to be conveyed to the place where it is to be hung up and dried. It is necessary to state that, if the operations were commenced by boiling the linen, the dirt would be fixed instead of being removed. Washing, therefore, precedes the boiling."

6361. *In some countries the manual operation of washing is different from the English mode.* In Paris, the *blanchisseuse* takes her linen, after soaking it with soap, to a large barge on the River Seine, and then, having dipped it into the water, she lays it upon the flat edge of the vessel, and beats it with a wooden beetle, dipping, rubbing, and beating alternately until all the dirt is removed. It may be supposed that this will wear the linen much more than our mode, but it does not appear to be the case; and it saves much manual labour as well as fuel. In the country parts of Scotland it is usual to take the linen to a clear running stream, and not only to wash it there by hand, after having bucked what is most foul, but to beat it on a smooth flat stone with a round wooden mallet something like that of a paviour, and to tread it with the feet in a tub of water, beating, treading, and rinsing alternately, after which it is spread out and dried upon the grass; this process renders the linen beautifully soft and white, with little expense of soap. These simple methods have suggested the idea of using machinery for washing, which we shall speak of afterward.

6362. *The directions we have hitherto given for washing apply more particularly to linen and white cottons or calico:* we shall add some observations on the modes of managing with other fabrics.

6363. *Calicoes*, and all articles made of cotton, are more liable than linen to lose their colour and turn yellow by insufficient washing or lying by: the best way of restoring their whiteness is to get them bleached occasionally by country washing, where they can be dried in the open air in the manner described under "Bleaching." The use of chlorine, or of the bleaching liquid, has been attempted with this view; but, though extremely valuable and efficacious in the hands of manufacturers, it is scarcely safe in ordinary domestic economy, as it requires more care and experience than are usually met with, and without which the articles would probably be irrecoverably destroyed. For such as wish to try the experiment, the method of proceeding may be gathered from what is said in Chap. X., Book XVII., on "Bleaching."

6364. *With respect to printed cottons and muslins*, the use of soda is apt to discharge or injure the colours, and is therefore better omitted, using soap only.

6365. *To wash Nankeen so as not to discharge the Colour.*—Put it to soak for twenty-four hours in cold water into which a handful of salt has been put; then wash it in warm lye without soap, and do not wring it.

6366. *Flannels, worsted hose, and other woollen articles* require particular treatment. It is the nature of all woollen textures to shrink considerably if put into hot water, from their property of felting, as explained under "Woollen Manufactures;" and it is therefore a good practice to shrink the flannel before it is made up into any article of dress, by soaking it in water very warm, otherwise, perhaps, it will be found too little after washing. Cold water shrinks woollen less than hot, but it is not always sufficient to remove the dirt; the water must generally be lukewarm; 85° is about the right temperature. All flannels will continue to shrink by washing in a small degree, but the Welsh flannel least. Soda should not be used for flannels or blankets: for farther directions respecting the latter, see "Scouring." Flannels should be well rinsed after washing, for any soap left in them will injure the texture.

6367. *Coloured silk* handkerchiefs require peculiar care, and are generally the worse for washing. India handkerchiefs wash best. Soda should not be used; and they should be washed with soap as expeditiously as possible in cold soft water, and perhaps afterward in a lather only lukewarm, and immediately rinsed and dried, as remaining long in the soap injures the colours. Such as are soiled by snuff require soaking over night.

6368. *It is not usual to wash silk dresses:* these are generally sent to the scourer's or dyer's; or they are turned, where economy is consulted. Nevertheless, they may be washed by using a particular method. To succeed, it is best to take the dress to pieces, or at least in great part, where there are many folds. The silk should then be laid upon a smooth board, and rubbed one way, a portion at a time, with a piece of flannel well soaped, with lukewarm water. When the dirt is removed, a sponge well wetted in cold water must be used to remove the soap. One side being done, the other must be treated in the same manner, taking special care to leave no soap on the silk. After this washing it is not to be wrung, but simply hung up to dry in the shade in the air, or on a horse within doors, for the sun will injure the colour. Some finish it by sponging it with gin; but whiskey or spirits of wine are preferable, as the sugar in gin will render it clammy. Silk ribands may be cleaned by the above process. Silk stockings may be washed with soap, then laid smooth, and dried by rubbing them with flannel. If they are ironed, the iron should not be very hot, and a fold of blanket should be interposed. Some prefer mangling.

6369. *Blonde and lace* are among the most difficult things to wash. This, however, may be effected by winding it round a glass bottle in a single fold, then covering this with two or three folds of muslin. Soak this in clean strong soap-suds, and rub and press it through the muslin till the dirt is removed. Rinse it well without taking it off, and apply to it a weak solution of gum Arabic in water to stiffen it. Dry it nearly by applying to it clean cloths; and, as it is unrolled, finish by ironing, or glazing with a glass bottle. If the articles are too large for a bottle, a smooth cylinder of hard wood may be used.

6370. *All articles that are very dirty,* such as kitchen cloths, dusters, &c., should be washed by themselves, otherwise they become a dye for the rest, which are thus infallibly spoiled. To free them from grease, they should be well soaped and soaked over night. To save soap in such cases, where that is expensive, a soapy liquid or lye may be made in the following manner, to soak them: Mix potash or soda and quicklime with water, and let the mixture stand till it becomes clear; then pour the clear part off into a vessel, and keep it for use. When the liquid is wanted to be used, add to it a thirtieth or fortieth part of oil, and shake them together: a milky compound will be formed, which is liquid soap. This may be put into the water in which the things are soaked, and will answer the same purpose as soap. Care must be taken not to put too much oil, otherwise it will not all mix, but some will float upon the surface. The difficulty in using lyes of this or any other kind is from the excoriating effect which they have upon the hands when too strong: the use of the oil is to prevent this. For a utensil for washing very dirty clothes, see Chap. VII., "Construction of the Wash-house and Laundry," &c.

Sect. II.—Drying.

6371. *It is not sufficient that linen is well washed, if it be not likewise dried in the best manner,* since the whiteness and good appearance depend much upon this. The smoke of towns is evidently injurious, from the particles of dust and soot which fall and attach themselves; hence the best laundresses generally reside on the outskirts of towns, to have the advantage of drying as much as possible in the open air, by which they also save some expense in fuel.

In treating "On Bleaching," Book XVII., Chap. X., we explained the effect which the sun, air, and water have in destroying colours; hence we may easily understand the use of drying white linen or cottons out of doors; and why exposure for some time to the rays of the sun, and occasionally sprinkling water on white linen hung out to dry, have a powerful effect in whitening it. This method, indeed, is often resorted to when linen has acquired a bad colour, from injudicious washing, lying by, or any other cause: it thus undergoes a kind of bleaching. The superiority of washing in India is to be ascribed to the great power of the sun's rays acting upon the calico often wetted.

Great care should be taken with respect to the mode of hanging up the linen to dry, avoiding palings, or any materials that may communicate a stain, particularly from iron, as this will cause iron-moulds.

In the country, or where there is convenience, a drying ground is frequently attached to the laundry, or in some situation proper for the purpose, to which the linen is carried in clean baskets. It is then usually hung upon lines fastened to wooden uprights, which should be fixed to the ground by permanent sockets, as they can thus be more firm and secure than when driven into the ground. One end of the lines is made to pass over a pulley at the top of an upright, by which the clothes may be raised or lowered together. The lines should be of worsted or soft flax.

The various articles are best secured to the lines by wooden pegs made of a branch, and having a cleft, which is bound at one end by a hoop of iron, tinned, to prevent rusting. For want of this tin the end may be bound very tight by packthread, or it may be let into a socket of wood. It is advisable to have a sufficient stock of these wooden pins, as common pins are apt to tear the articles hung up. When linen is laid upon grass to be bleached, it is often necessary to keep it down by clean stones, and to have it well watched for fear of its being blown away or stolen.

6372. *But the same cause which renders drying in the sun beneficial to white linen renders this injurious to all dyed and printed articles*, as being destructive to colour. These should, therefore, be dried in the shade, and never hung in the sun: it is the sun's rays, and not merely the air, which particularly occasion colours to fade. There may, therefore, be a shed for the purpose of drying coloured articles, or some place may be selected that is sheltered from the sun's rays. It is not uncommon for printed cottons to suffer considerable injury for want of this precaution, either from negligence or ignorance of the principles we have mentioned. Some articles require particular modes of hanging them up to dry. Very thick articles, as quilts, waistcoats, &c., are best hung over two lines placed a few feet apart, in order that both sides may be sufficiently exposed to the air. The summer months are best for washing thick and heavy articles of furniture, as blankets, counterpanes, bed curtains, &c., on account of the greater facility with which they may be dried out of doors in that time of the year, and thus, also, acquiring a better colour. Laces and lace veils require to be stretched smooth, and tacked to a piece of white calico before they are hung up. Muslin and other dresses must be stretched as smooth as possible, that they may not get wrinkled in drying. But it is unnecessary to detail all the little precautions to be observed in hanging out various articles of dress, since these are sufficiently understood by those who are practised in it, and scarcely admit of being explained by any short directions. But, notwithstanding the superiority of drying clothes in the open air, this is not always practicable, and they are then dried within doors. We shall describe the best methods of effecting this when we treat of the "Construction of the Laundry."

SECT. III.—STARCHING.

6373. As it is necessary to have certain parts of linen and various articles of dress less pliable than usual, starch is employed to give the requisite stiffness. The chemical nature of starch, and the process of manufacturing it, have been already explained.

6374. *To make the starch for use*, it must be mixed with a sufficient quantity of cold water, until it is about the consistence of common paste, carefully breaking all the lumps, and rubbing it with a wooden spoon till it is quite smooth: then add boiling water in the proportion of a pint of water to an ounce of starch; put the blue flannel bag into it, and let enough colour be dissolved to give the required tint. The making of starch properly requires some care. If made in a tin sauce-pan, it is a chance if it does not burn, like all thick liquids. The best vessels for making it in are a bell-mettle skillet, or a copper vessel, tinned, or an earthen-ware pipkin. It is said that an iron vessel would make it turn black; but this is impossible if the iron is tinned: a small cast-iron sauce-pan, tinned inside, will answer very well.

The starch being properly mixed, put it on the fire and let it boil, taking care to stir it all the while, to prevent burning. When it is taken off the fire and poured out, cover it with a plate, to prevent a skin forming. If it be wanted stiffer than common, a little gum Arabic or isinglass dissolved may be added: and for some articles of lawn, gum Arabic alone is used, without starch. Some add a bit of white wax.

6375. *As an economical kind of starch*, for articles where no nicety is required, some use common paste made of wheat flour.

6376. *The parts of linen and other articles of wearing apparel that require to be starched* are too well known to demand enumeration, and even these vary somewhat with fashion; the process of starching consists merely in dipping the part into the starch, and squeezing it.

6377. *What is called clear starching* is the starching of laces, muslins, and other transparent tissues, which requires to be done with peculiar care; for these the starch is made thicker and hotter than ordinary, and the articles, after having been well washed, rinsed, and dried, are dipped into the thick starch, previously strained, before it is quite cold. After squeezing them out, they are clapped between the hands, to produce clearness. Instead of clapping, which is apt to injure lace, some prefer, after starching and squeezing out, spreading them on a linen cloth, rolling them up in it, and letting them lie for an hour, when they will be ready for the irons. Muslins and cambrics do not require the starch so thick as net or lace. If the articles are too dry for the iron, they may be damped again by rolling them in a damp cloth; but this should, if possible, be avoided. All linen, after starching, requires to be made nearly, though not quite, dry before ironing.

6378. *It is sometimes found that starched laces and muslins stick to the iron*, and several methods of preventing this are employed. Some recommend drying the things first, then dipping them in the starch before it is quite cold; then dipping them in cold water, and drying them again; once more dipping them in cold water, spreading them on a dry cloth, and rolling up previous to ironing: by this process sticking to the iron is prevented. Some put a little tallow, hogs' lard, or olive oil in the starch; but a lump of refined sugar is preferable. In India all muslins are stiffened with rice water, which is said to be excellent; and the rice starch is said not to stick to the irons.

CHAPTER VII.

IRONING AND MANGLING.

6379. Linen and cotton, or cloth of any kind, after being washed and dried, is full of wrinkles, and a beautiful smooth appearance is to be produced by ironing or mangling. The last is the most expeditious, and least apt to injure the colour, but can only be applied to the large articles, the hot iron being necessary where there are many folds, or where the texture is too delicate for the mangle.

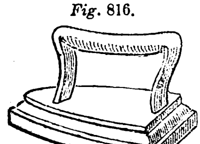
6380. *Previous to ironing*, all linen and other articles, after being washed and well dried, must be properly folded, and slightly damped by sprinkling water upon them just before the application of the hot iron. The proper degree of dampness is a nicety learned only by practice, but it is essential to the success of good ironing.

6381. *Ironing is a very important part of what is termed the getting up of linen;* bad ironing is known by the creases left, and inaccurate folding, and sometimes by the marks left by ill-cleaned irons, or even iron-moulds. To iron well, it is necessary not only to be dexterous in the use of the iron implement, but also it is essential that the mode of heating the irons should be effectual.

6382. *Smoothing irons* are employed to give smoothness to such articles of wearing apparel as do not admit of being wound round a cylinder to be mangled. These implements are of three kinds: the common flat iron, termed among ironmongers the sad iron; the box iron; and the Italian iron. The first is so named because the word sad in the North means solid.

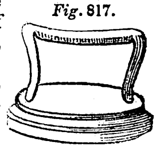
6383. *The common flat iron* (*fig.* 816), which is most frequently employed, is well known. They are manufactured of various sizes, varying in length from four to nine or ten inches. The body is of cast iron, ground smooth at the bottom, and the handle of wrought iron, turned round so as to be hollow. The larger the irons, the longer they retain the heat, and the greater the pressure they are capable of giving. Small irons are employed for more delicate articles.

Fig. 816.



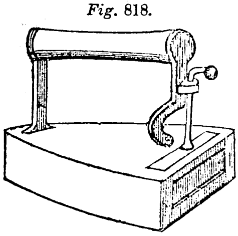
6384. *The oval flat iron* (*fig.* 817) is sometimes employed for the cauls of caps, or such things as might be apt to be torn by the pointed iron. It is to be observed that it has of late become usual to make the last iron (*fig.* 816) round at the point, instead of being sharp as formerly, and as represented in the cut.

Fig. 817.



6385. *The box iron* (*fig.* 818) is an oldfashioned implement, less used than formerly, but ingeniously constructed. As considerable pressure is frequently useful, this iron is made large and heavy; and to retain its heat longer, it is made hollow, the cavity containing an iron heater, which is made nearly red hot occasionally as the iron cools. To keep this heater in its place, an iron slider is made to shut down in front. Accidents of burning have sometimes happened by lifting these irons negligently, without seeing that the slider was down, so as to allow the heater to fall out.

Fig. 818.

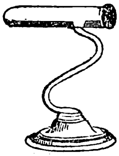


6386. *The proper degree of heat in the smoothing iron is very necessary to attend to*, and which can only be learned by practice. Before using it, it is proper to try its effect upon a piece of blanket kept on the table for that purpose; if the iron be too hot, it will scorch the linen, and if not hot enough, it will not properly perform its office. In the first case, it may be proper, not to lose time, to iron some coarse thing that a very hot iron will not injure. The best manner of heating the irons will be described under "Construction of the Laundry."

6387. *The use of the iron* in the various articles of wearing apparel can be learned only by practice under a skilful instructer; no verbal directions can be sufficient. A few hints, however, may be given. Things that require to be very flat, as shirt collars, are best to be covered by a towel in the first ironing, and then gone over on both sides with the box-iron. Laces and worked muslins require a very soft and good ironing blanket, and they are to be dried by rolling them up, and to be unrolled as they are ironed. When silks are ironed, they should be covered over with paper to prevent the iron from touching the silk itself, which produces a disagreeable glossiness. Great care must be taken not to scorch anything, for this is in fact reducing a portion of the surface to charcoal; and though receipts are given for restoring the colour, these are nearly, if not quite, useless.

6388. *The Italian iron* (*fig.* 819) affords a very neat and expeditious way of ironing certain articles, as frills, that require to be puffed. It is a hollow tube, and is heated by a cylindrical piece of iron made red hot and inserted in it. The articles to be ironed are drawn over the iron, instead of passing the iron over them.

Fig. 819.



6389. *Plaiting* is used in frills, breasts of shirts, and similar parts of dress, and is either *small* plaiting (*fig.* 820) or *box* plaiting (*fig.* 821). The plaits are first folded with the fingers, and then ironed down flat with the box heater, or a heavy common iron. If any part of the articles to be ironed have become too dry, they must be re-damped; and should the iron stick to the linen, it should be well rubbed with a coarse cloth; and should that not be effectual, it must be rubbed upon a board on which a little brickdust or powder of cuttle-fish bone has been scattered, wiping the iron afterward.

6390. *Crimping machines* (*fig.* 822) are for performing a kind of plaiting or fluting on

Fig. 820.

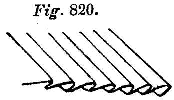


Fig. 821.

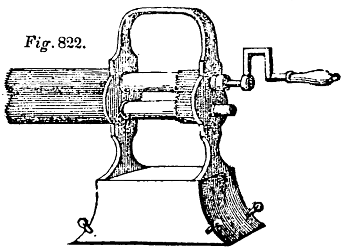
Fig. 822.



frills with much greater regularity and expedition than could be practised by hand. This is done by grooved rollers, heated like the Italian iron. The process is performed merely by putting the articles between the rollers, and turning the handle.

6391. *Gauffering machines* differ from those used for crimping only by having the grooves much larger and less regular.

6392. *The following method of gauffering by means of straws* is given in the "Workwoman's Guide:" Procure a board about a yard long and six nails broad; cover it with flannel, and fasten two tapes lengthwise, leaving about a quarter of a yard between them; then pin the net to the flannel at one end, and place a straw over the tapes (between which the net is lying) and under the net; the next straw is laid under the tapes and over the net, and so on alternately, taking care that the upper straws are put close to each other upon the under ones, forming two layers of straws. When all the net is folded, dip a coarse cloth in water, and wring it as dry as you can; lay this upon the net, and iron it dry, pressing on the board as much as you can without splitting the straws; remove the cloth, and place the board before the fire for half an hour, when you may draw out the upper straws, and run in some cotton to secure it; after which the remaining straws may be taken away, and the work is complete. Some persons hold the board in the steam of a kettle for some time, and then dry it before the fire, in preference to ironing it; others sprinkle it with starch, gum, or rice water, before ironing.

6393. *Plaiting and crimping are operations which have been long in use.* There is reason to think, from their sculpture and paintings, that the Egyptians plaited their drapery; and other ancient nations followed occasionally a similar practice. In Queen Elizabeth's time they used, for this purpose, what are called *poking sticks*, which were first made of wood or bone, and afterward of steel; and the ruffs then in vogue were plaited with great care.

6394. *Mangling* is a mode of smoothing linen that gives a beautiful flatness and even gloss not to be effected by ironing, and it is used on this account, as well as for expedition, in all the larger articles, such as table and bed linen, as well as various articles of dress; but things of a delicate tissue, or where there are folds and plaits, cannot be mangled without injury. The best construction of mangles will be described when we treat of the furniture of the laundry.

CHAPTER VIII.

CONSTRUCTION OF THE WASH-HOUSE AND LAUNDRY, AND DESCRIPTION OF THE FURNITURE AND APPARATUS USED.

In the most complete establishments these offices are always detached from the house.

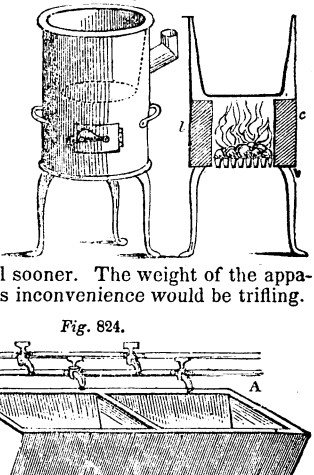
6395. *The wash-house may be fitted up* in the following manner: The floor should be of Yorkshire or other stone, laid with a sharp current towards a sink-stone, for the convenience of keeping it as dry as possible. In the roof there may be a cistern for rain water, which may be collected from this and the adjoining buildings; or, if that be inconvenient, a tank may be formed in the ground, with a pump to raise up the water.

6396. *The copper* for heating the water should be placed lower than the supply cistern in the roof, whether of rain or other water; and on a lower level than that should be the copper for boiling the clothes, so that the latter may be filled from the former by a pipe, which will save much trouble. In some cases, a filtering apparatus may be useful in case of sediment or impurities in the cistern. On a small scale, the copper is generally made round; but when very large, an oblong form is preferable, on account of the setting in brick-work, and the economy of fuel. In that case, the cover may be hinged, and made to open by a rope and pulley. A steam rim, such as that described under "Kitchen Furniture," may surround the edge, to prevent the steam from coming into the wash-house, except when it is opened.

The copper for boiling the linen should be furnished with a copper colander for holding the linen, which should be drawn up by a jack and pulleys. The jack should have a ratchet to keep the colander suspended over the copper till the water is drawn from the linen, which can then be turned out altogether into the rinsing tub; by which the usual mode of poking the linen out by a stick, which sometimes injures it, is avoided. All the coppers should be furnished with brass cocks, to let off the water.

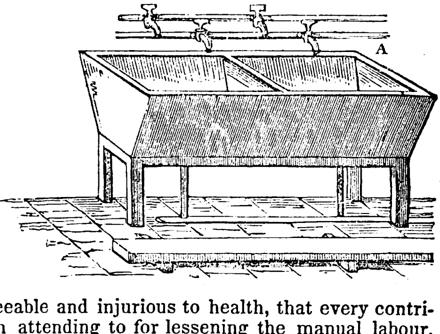
6397. *A portable copper* is very useful for heating water for washing, where there is no fixed one, and likewise on many other occasions where boiling water is wanted. The copper, *a*, *fig.* 823, is suspended by its rim in a cylinder of sheet-iron, which contains the fire. In the manner in which they are usually made, this iron gets extremely hot, sometimes red hot, and not only heats the apartment intolerably, if small, but is very apt to set fire to the clothes of those who use it. This apparatus would be much improved by lining the part which contains the fire with brick about two inches in thickness, as at *b c*. Windsor brick should be used, that bear the fire, and are so soft as to be cut. This would prevent the over-heating of the iron cylinder, would make it last much longer, and would cause the water to boil sooner. The weight of the apparatus would, of course, be a little increased; but this inconvenience would be trifling.

Fig. 823.



6398. *The wash-tubs*, large and small, are usually round, and raised upon blocks or forms; but some prefer having them of an oblong shape, narrower at the bottom than at the top, *fig.* 824, and with a groove running all round on the edge, to carry off the slop that is made. They should be placed in a good light, in a range as numerous as is necessary, and each should be furnished with pipes, A, having cocks for hot and cold water, and should also have one at the bottom for letting off the soap-suds into a waste-pipe, which goes into the drain or a cesspool.

Fig. 824.



The labour of washing is so disagreeable and injurious to health, that every contrivance which may facilitate it is worth attending to for lessening the manual labour, and even for improving the process itself. Besides the wash-tubs, there must also be proper rinsing-tubs, and trays to put linen upon, linen-baskets, folding-horses, clothes-lines, and pegs. A good wash-house should be 24 feet long, 10 feet wide, and 9 or 10 feet high; but this, of course, must be modified according to the work required.

6399. *A serious objection to washing at home arises from the steam* diffusing itself through the house, rendering the air damp, and spoiling the furniture, besides the destruction of comfort. In a wash-house constructed on purpose out of the house, ventilation is easily effected by an aperture in the roof properly contrived to carry off the steam. See Book III., "On Ventilation."

6400. *A method of destroying the steam* has lately been invented, by which it may be got rid of in any situation, and is actually here converted into fuel, and made to assist in heating the copper. It has long been known that steam, passed into the fire of a furnace, is decomposed and converted into the elementary gases, hydrogen and oxygen; and it had been observed that, when only a small stream of water was played against a house on fire, it assisted instead of preventing the combustion. Waste steam is now burned in manufactories, by conducting it into the air-flue that feeds the fire; and is thus employed in wash-houses, breweries, and several large establishments. Dr. Fife, in a paper in Jamieson's Journal, July, 1837, has shown that a great accession of heat may be gained by this process.

6401. The method of effecting this is very simple. "The boiler is kept closely covered; but at one side, that next the wall, there is a flue of communication between the upper edge of the boiler, immediately under the lid, and another flue which conducts the air down to the ash-pit. By keeping the ash-pit door shut, no air is admitted to the fire but what is drawn through this flue; and, of course, it draws down the steam along with it, and both air and steam pass upward through the fire. By having the upper opening of the air-flue immediately under the ceiling, in the case of wash-houses, breweries, &c., any steam from the washing-tubs, or any vapour which may be floating in the atmosphere, will be drawn down and consumed." Thus the wash-house, which at present is a most unwholesome and disagreeable place, may be much improved, although it will be still impossible by this contrivance to get quit of the steam that escapes when the cover of the boiler is taken off, or what rises from the wash-tubs.

6402. *The laundry should adjoin the wash-house*, and may be 18 feet square, and 11 or 12 feet high. It should be well lighted; the floor should be level, of rubbed Yorkshire stone, laid upon brick piers, to keep it perfectly free from damp. It should be furnished with a mangle, or that may be better in a separate small room, a furnace for heating the irons, an ironing board 12 feet by 3 feet, clothes-horses, large drawers for the ironing cloth, iron-holders, &c., proper places for putting away the clothes-baskets, and a place for coals. In small establishments, the laundry usually serves for the double purpose of drying and ironing the linen, particularly when there is no convenience for drying in the open air, the advantages of which have been already explained; and notwithstanding the superiority of the latter method, yet, by proper arrangements, it is possible to dry clothes perfectly well, and with a good colour, in doors.

6403. *When the laundry is used as a drying-room, the air is necessarily kept very hot and damp*, which renders it very unhealthy for the laundry maids. The usual method of heating it is by an iron stove and iron pipe for the passage of the smoke, which is simple and effectual, though less wholesome than by pipes filled with steam or hot water. It is essential that a draught or current of air should be excited in a drying-room, or a laundry used as such, to carry off the moisture from the linen. This current may be obtained by keeping a part of the upper sashes open, or panes to open, and likewise by having an opening at the lower part of the door.

6404. When a laundry is built on purpose, proper ventilation may be easily provided by proper lubber boarding in the roof; but it must be observed that it can never be expected that the hot air can pass out at the top except proper openings are made somewhere at the bottom to supply its place. Sometimes a room in the attic story can be spared, and this may be advantageously converted into a drying-room, since there openings in the roof may be easily obtained. The oldfashioned high roofs, so common on the Continent, are very convenient for this purpose, for which they are often employed, as well as for drying stores of various kinds. When the laundry is a separate building, the drying may be placed over the ironing-room. When there is no drying closet, the clothes are hung up in the laundry on standing or leaf-folding horses, or lines stretched across, or, what is better, on frames with horizontal bars suspended to the ceiling, and raised and lowered by a rope and winch.

6405. *The best method of drying in doors is by a drying-closet* adjoining the laundry and wash-house. By this the health and comfort of those employed are greatly promoted, by their being almost entirely freed from the pernicious effect of damp vapour, and in not being incommoded by great heat in hot weather; and the linen is kept quite free from smoke and dust. The drying-closet may be 8 feet by 6 feet, and may contain four wooden horses, each with five rails or bars. Each horse runs in and out of the closet upon two small iron wheels upon an iron railway. One such horse will hold six shirts, or a proportional quantity of other linen, and the whole will dry off as much and as speedily as six women can wash in succession; or the drying-closet may be so small that two horses only can be used, and the heat may be sufficient to dry the linen in an hour. The same furnace that heats the irons may likewise heat this drying-closet, by making the flue continue round the bottom of it before it is carried to the top of the building. The top of the horizontal part of the flue must be of cast-iron plates, and a few inches above it the above-mentioned iron railway is laid, between which and the flue there is a flooring of wire-work, to prevent any accident from the casual falling of linen upon the flues, but so as not to prevent the ascent of warm air. Level with the railway, inside the closet, there must be an opening 15 inches square, communicating with the external air. The ceiling of the closet should be in the form of an inverted hopper, terminating in a funnel of the same diameter (15 inches) as the external aperture. Both these openings are furnished with sliding doors, which open and shut, as required, by pulley-cords. like sashes. The principle upon which it acts is by heating it to a degree sufficient to excite a strong evaporation from the wet linen, and carrying off the moisture by means of the two openings. During the time of its acquiring this heat, both the openings and the horses are kept closely shut, so that the closet is nearly air-tight. As soon as the proper degree of heat is obtained, both the vents are to be opened, when a strong current of air rushes in at the lowermost, carrying up all the vapour from the linen through the upper opening or funnel, and thus the drying is very speedily completed.

6406. *But the best mode of heating the drying-closet is by means of a steam-pipe* passing through it; the steam may be furnished by a small copper placed in the wash-house. This will obviate any danger that there may be in heating it with a smoke-flue or iron pipes, which, except very great care is employed in the construction, will exist. In case of using steam, the drying-closet may be constructed entirely of wood, taking care that the joints are made in such a way as not to open by shrinking.

Fig. 825 represents the longitudinal section of such a drying-closet, and *fig.* 826 is the transverse section. *a*, *a*, *a*, *a* is a steam-pipe traversing the interior of the closet, which is seen at bottom again, surrounded by an enclosure; and the air that enters by an aperture underneath is heated, and issues into the bottom of the closet; on each side of this steam-pipe, in the interior, is a horse on rollers for the linen, which is represented, in *fig.* 825, as partly drawn out by a handle. In the transverse section, *fig*, 826, this horse is represented with linen hanging on it. The hot air, with the moisture, passes off at each side through a narrow aperture that communicates with an upright tube, *b*, that can be closed as much as necessary to regulate the draught by a valve turning on a centre.

Fig. 825.

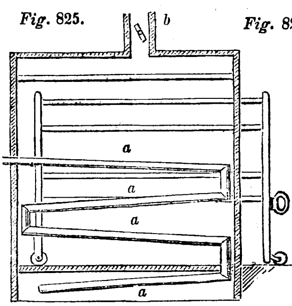


Fig. 826.

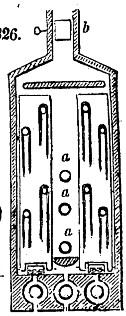


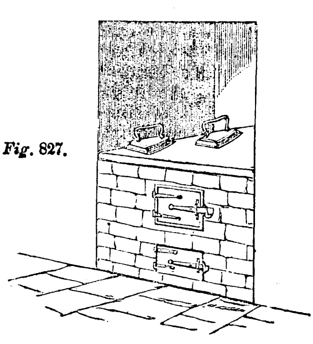
6407. *Drying-houses* are constructed for drying calicoes and other similar fabrics in manufactories on a large scale. They are heated by steam passing through pipes in the drying-house; the cloth is suspended on lines, and the vapour is carried off by apertures in the roof. The advantage of the steam is, that it is quite safe, and that the place can never be overheated.

6408. *A cleanly and expeditious mode of heating smoothing irons* is very essential in a good laundry. In a very small way, these irons are heated by placing them on a moveable iron shelf hung on the bars of a grate; but in this manner they are very apt to be soiled by the ashes and coals, and require very careful wiping to prevent staining the linen. To obviate this inconvenience, *ironing stoves* are constructed, by which the irons are heated without the possibility of their contracting any dirt.

6409. *The best ironing stove is a recess in the wall*, like a small chimney, *fig.* 827, with a hot plate and furnace below it, in the same form as the hot plate described among the apparatus for the kitchen. Upon this hot plate the irons are set to be heated; and there should be an air-flue above this plate, to carry out the hot air and prevent its incommoding the laundry. Generally, however, the ironing stoves are detached, and stand in the laundry, and then answer the double purpose of warming the room and heating the irons.

Fig. 828 is one of the smallest kind; it is all of iron; the fire is contained in the box

Fig. 827.



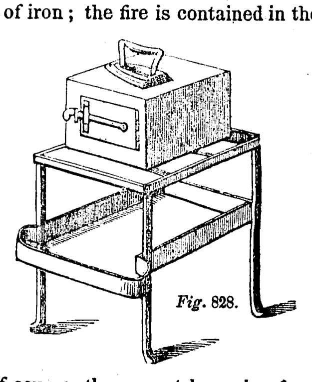


Fig. 828.

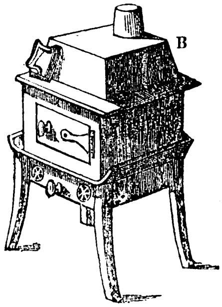
on which the smoothing-iron is placed, and, of course, there must be a pipe from the back to carry off the smoke into the chimney-flue.

6410. *Fig.* 829 is a larger one, to hold several irons all round. *Fig.* 830 is one still

Fig. 829.



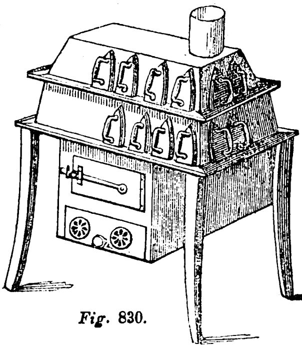


Fig. 830.

larger, for two rows of irons. Both these have registers to the ash-hole, to regulate the draught; by merely closing these, the fire will keep in with very little consumption of fuel, particularly if anthracite be used.

6411. *Joyce's apparatus for heating Italian irons, fig.* 831, is a sheet-iron cylinder within another about four inches wider, the inner one being filled with lighted charcoal, and the space between empty; four cylindrical pieces of brass pass through this space, and enter into the fire-chamber, by which means they are heated sufficiently. The fumes or deleterious gas formed by the combustion of the charcoal pass out through the tube *a*, seen in the apparatus, and when the cover, *b*, is put on they issue through the holes in it.

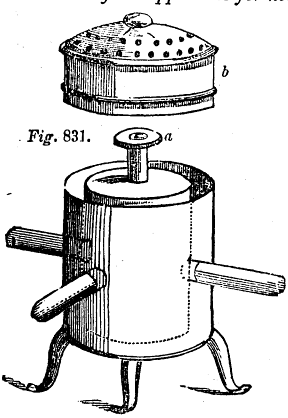

Fig. 831.

In contradiction to those who state that the fuel sold with this apparatus is charcoal, prepared in such a way as to *prevent it from giving out any noxious fumes*, we must observe that the charcoal *does give out* the same deleterious air (carbonic acid gas) as common charcoal; and therefore this apparatus should never be employed where a brazier of charcoal would be considered as unhealthy; no method has ever been discovered of depriving charcoal of its noxious quality when burning, nor is it at all probable that such discovery will ever be made.

6412. *The ironing board,* or table, should be very strong and steady; and for this purpose one end or side of it is generally placed against a wall. It should likewise be placed on the window side, to have the benefit of a perfectly good light. The iron-cloth, which is a kind of blanket made on purpose, of a proper width and thickness, should be double, and should be firmly and securely pinned down round the table, to prevent its moving. Its length must depend upon the quantity of work to be done and the number of persons employed in ironing.

6413. *The mangle* is a necessary article among the furniture of the laundry.

6414. *The common mangle* consists of a large square box loaded with heavy weights, usually stones, which is moved backward and forward upon wooden rollers placed on a level, strong table; and round these rollers the various articles to be smoothed are wound. The motion of the box is accomplished by means of straps fixed to each end, and passed over an upper roller carried round by a winch. By this machine the mangling is done sufficiently well; but the labour of working it is excessive, not only on account of the strength required to move it, but from the continual reversing of the motion; for scarcely has it been got into motion by great exertion than it becomes necessary to turn it back again, and thus power is wasted in constantly having the *vis inertia* of the heavy box to overcome. Its cheapness (the price being from £5 to £8) causes it to be most in use among the poorer laundresses.

6415. *Various patents have been taken out for improved mangles;* one of the best is Baker's mangle, in which the operator keeps always turning the winch the same way, and yet the box moves backward and forward as usual. A fly-wheel is likewise added to equalize the motion. This mangle usually costs from £12 to £18.

Another simple mangle consists of two cylinders placed near each other, as in the wringing machine, but with more pressure; round these the clothes are wound. Such a mangle may be made to take up very little room. Although the operation of the mangle has several advantages, as despatch and preserving the whiteness of the table linen, yet, if not very carefully managed, it may be very injurious to the texture of the cloth submitted to its pressure, particularly in articles where folds are necessary; the creases thus produced are very unseemly, but in the best table-cloths these are taken out afterward by ironing. When there are buttons, or hooks and eyes, in the parts of dress, they are often broken by the mangle, which can scarcely be prevented by any care; such things had better be ironed, or have the buttons taken off. Linen requires to be longer in the mangle than calico; and some things that demand a very high gloss should remain in the mangle all night.

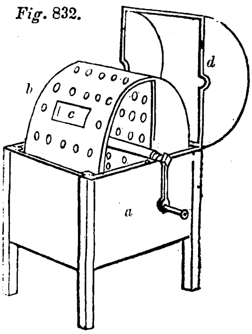
CHAPTER IX.

WASHING BY MACHINES.

6416. *Many attempts have been made to lessen the labour of washing by the use of machinery;* and although it does not appear that any method has yet been invented so simple and effectual as to do away entirely with the manual labour in the ordinary method, yet, as machine-washing has succeeded to a certain degree, and been found useful on some occasions, particularly in manufactories, hospitals, &c., it deserves consideration. One of the advantages of this method is, that hotter water can be employed than in the common way; and, likewise, that alkaline lyes may be used stronger than the hand can bear. Steam may also be combined with it; all of which has the effect of so loosening the dirt that very little hand labour afterward is sufficient.

6417. *A washing-machine was constructed by Mr. William Strutt,* being a modification of the common washing-wheel used by manufacturers, which was used in the Derbyshire Infirmary and other establishments, and is said to have answered completely, at least for the purposes to which it was applied. *a, fig.* 832, is a water-tight cistern, in which a hollow cylinder, *b*, is made to revolve by means of a winch. This cylinder is divided into four parts, internally, by partitions, and a portion of the end of the cylinder is represented as removed to show the inside; these partitions, as well as the cylinder itself, are perforated by numerous holes; and there are larger apertures with doors, *c*, through which the clothes are introduced into the divisions of the cylinder. The linen is well wetted and soaped, or dipped into a soapy liquor, or an alkaline lye, the night before washing. Before the operation commences, as much water, nearly boiling, is put into the cistern as will rise to the height of four or five inches within the cylinder. The clothes are then introduced into the cylinder, and the latter is turned round by the winch. It is necessary to regulate the velocity of the motion very exactly; for, if this be too quick, the clothes will apply themselves close to the sides of the cylinder from the centrifugal force, and if the motion is too slow, they slide down the sides, in either of which cases little effect is produced. The velocity should be such that the linen may be heard to fall from one side to the other every time it is raised out of the water. This discharges most of the water from it, and it becomes filled with a fresh portion every time it dips into the water below. The quantity of soap employed should be such that a strong lather is produced; and if enough has not been rubbed in the linen, some more must be added by cutting thin slices, or some soapy mixture may be used. The process of washing one change of linen may require half an hour; and, to keep the water hot, a pipe may convey steam into the cistern. A cover, *d*, hung on hinges, is made to shut down over the cylinder when it is revolving. The edge of the cover fits into a groove which goes round the top of the boiler, and which, being filled with water, prevents the escape of the steam. When this operation is completed, a little hand washing may be found necessary; and, finally, the clothes must be rinsed and boiled as usual. Previously to rinsing, when the clothes are taken out of the machine, they may be laid upon a tray with holes placed over some vessel, which shall receive the soapy water that drains from them, and which may be used again in the machine until it is too foul. It may be observed that, in cases where a strong alkaline lye is required, pearlash may be used as more economical than soda, although the latter answers very well. An alkaline lye may be prepared from common potash thus: dissolve it in its own weight of water, stir it frequently, and then let it stand for half an hour to settle; pour off the clear liquor for use; it will contain all the alkali, the sediment being impurities.

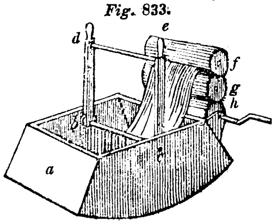
Fig. 832.



6418. *For some common purposes,* and where articles are very dirty, the alkali may be made caustic in the following manner, by the addition of lime; but this must be used with great caution, otherwise, as has been already stated, it will corrode and destroy the texture of the linen. Put common pearlash in a stone jar with five or six times its weight of water; let it stand till it is quite dissolved, and add as much weight of fresh slacked lime as that of the pearlash; stir this mixture frequently for several days, and let it stand to settle; then pour off the clear liquor, and keep it for use in a stone bottle well corked. A small quantity of this caustic solution will be more effective than soap for particular purposes; and it is to be observed that alkali may be employed without danger to some articles that would be too strong for the washerwoman's hands.

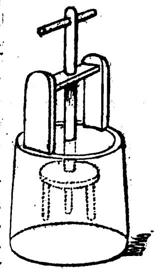
6419. *Another washing-machine sufficiently simple* is represented in the wood-cut opposite. *a*, *fig*. 833, is a box to hold the clothes and the water, with alkali or soap, in which is a frame, moveable backward and forward on the centres *b* and *c*, by means of the handles *d* and *e*. The lower part of this frame consists of a series of wooden bars to agitate or beat the linen until the dirt is removed.

Fig. 833.



6420. *The Dolly*, *fig*. 834, is a useful implement for washing such clothes as are very dirty, and is used in many laundries. It is in form somewhat like a small churn, and strongly hooped. Two uprights and a cross-piece support a shaft with a cross-handle; on the lower end of the shaft, and inside the vessel, there is a circle of wood containing three or four strong projecting pegs. When the clothes dipped in lye have been put into this vessel, with water, the shaft is turned round sharply by the handle, and by the dashing them about they are sufficiently cleaned without the usual manual labour.

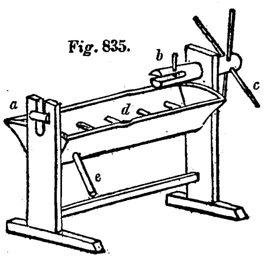
Fig. 834.



6421. *Machines for wringing the clothes* after washing and boiling have also been contrived; and it is observed that the ordinary process of wringing by hand is peculiarly destructive to wearing apparel, especially such as is of a delicate texture. One construction of this apparatus is the following: the linen is put into a square bag of strong sacking, kept open by wooden hoops; this bag is put into a strong box, which opens at one side to admit the bag, and then is closed firmly. The interior surface of the box is grooved to let the water out when pressed. A cover that fits the inside of the box is put in over the bag, and a strong pressure is applied by a lever to the cover, or by a rack and pinion. The pressing down the cover forces the water out of the clothes, which thus receives less injury than by the usual twisting.

Another wringing-machine is represented as attached to the washing-machine, *fig*. 833. *f*, *g* are fluted rollers for the clothes to go between, covered with several folds of flannel to give elasticity to the pressure, and prevent injury to the fabrics. The cylinders have toothed wheels on the end, and are moved round by a small pinion, *h*, turned by a winch The cylinders are capable of being placed at a distance from each other suited to the several articles; but the contrivance for this, as well as the upright stand by which they are supported, are here omitted.

Fig. 835.



6422. *Another wringing apparatus*, *fig*. 835, is described in Loudon's "Cottage Architecture" as useful in small families. The articles to be wrung are taken out of the wash-tub, and being passed over the pin at *a*, the two ends are put through the hole of the twister, *b*, which is turned round by the spokes, *c*. The water drops into the trough, *d*, from which it runs off into a tub or other vessel, through the tube *e*. When small articles are to be wrung, they are put into a coarse hempen bag, which is then treated as above mentioned. This machine does not wear the linen more than common wringing.

CHAPTER X.

WASHING BY STEAM.

6423. Washing by steam has met with little encouragement in England; yet it has been practised many years ago, and has been employed with great success in France. It was first tried by Chaptal, a celebrated French chemist, and the process was improved by Cadet-de-Vaux and by Curandeau, and, lastly, by M. Bourgon de Layne. The process is very simple. The clothes are first soaked in a lye of potash, and then hung in a large vessel kept full of steam by a pipe communicating with a boiler. This vessel for the clothes must be steam-tight; and, on a small scale, a large cask will answer. After remaining a certain time in the steam, generally half an hour, the dirt becomes loosened, and little labour in a subsequent washing is sufficient to detach it by washing with soap. The saving of fuel and labour is thus very great, and the linen is rendered extremely white.

It is stated in "L'Echo du Monde Savant," June 7, 1837, that blankets are washed by these means in Paris for a farthing a pair. We have known washing by steam practised in a tradesman's family in London with perfect success. It should be stated that it will only answer for white articles, for the action of the steam is so powerful as to discharge the colour of dyed things. It is likewise necessary to observe that the linen should be suspended in the steam vessel in such a manner that it shall not come into contact with the suds that drain from it, which, in this case, would produce a bad colour difficult to wash out. Also, it is essential that no iron should be admitted in the apparatus, lest rust should come in contact with the linen. A large copper tea-kettle will produce steam enough for a moderate washing; and to fill with steam the vessel in which the clothes are put, it is necessary to leave an aperture open, at first, by which the common air may be driven out as the steam enters, and which should be shut as soon as the vessel is full of steam; for it is to be observed that the vessel cannot be filled with steam, while, at the same time, it remains full of air; the latter must be driven out, that the steam may occupy its place.

CHAPTER XI.

MARKING LINEN.

6424. *The marking of linen* being connected with the business of the laundress, we shall introduce the subject in this place. Marking has usually been practised with the needle, and still must be for blankets and woollen articles, but linen and cotton can be more conveniently marked with an ink that is indelible by the ordinary processes of washing; observing, however, that this will be discharged wherever the bleaching liquid is used.

6425. *The best marking ink is made in the following manner*, which it is useful to know, as in some places it cannot be purchased or depended upon. Get one drachm of lunar caustic (fused nitrate of silver), which every surgeon keeps; dissolve it in less than half an ounce of pure water (distilled or rain is best), having put into it a drop or two of nitric acid; but this is not essential. This forms the ink; but as it is yet colourless, the writing done with it would not be visible, and it would be too thin. To give it a little colour, add to it a little indigo, or even a drop of common ink; and to give a little thickness, add a very little gum, which by itself will give a greenish colour. To prepare the linen to be written upon, dissolve an ounce of salt tartar (sub-carbonate of potash, the common potash used for washing) in an ounce and a half of water. Wet the linen with this preparation, and let the place dry completely: when the part is dry, rub it with something hard to smoothe the surface, and write with the ink prepared as above. The writing will be indelible. Any one may easily make this ink; but it must be observed that lunar caustic will burn the skin if handled; it should, therefore, be lifted by a pair of pincers or scissors. The ink also makes a black stain upon the skin, which no washing will remove; it must, therefore, be used with neatness and care. If the ink is too pale, there is not lunar caustic enough in it; if there is too much, the ink will be apt to run or blot. Should it not be possible to obtain lunar caustic, the deficiency may be supplied by dissolving a bit of silver, as a small coin, in some aquafortis; the solution is nitrate of silver, nearly the same as lunar caustic, and will answer for marking ink with the addition of a little gum and colour. The vial containing the ink should be kept from the light by wrapping paper round it, or keeping it in a case.

A marking ink is now sold that requires no liquid as a preparation before writing with it. It is said to be indelible, but not being quite certain as to this fact, we cannot at present safely recommend it.

6426. *An indelible ink for printing on linen with types* may be made thus: Dissolve some asphaltum in four times the weight of oil of turpentine; add some lampblack or fine black-lead powder, so as to make an ink of a proper consistence to print with types. Or, take the black residuum after making oxygen gas by manganese and sulphuric acid; mix it with water, and filter it; mix the paste left on the filter with a little dissolved gum tragacanth. The cloth to be marked with must first be wetted with a solution of potash or soda, in the proportion of ten parts water.

CHAPTER XII.

SCOURING, REMOVING STAINS, ETC.

6427. *In England scouring comprehends* such processes for cleaning silks, cloths, woollens, lace, and other articles as do not come within the province of the laundress. The mode of proceeding is more varied and difficult than that of ordinary washing; hence the scourer has become a distinct trade. Those who practise it possess a good deal of knowledge which is not usually attained completely in domestic economy; and when various articles of dress and furniture cannot be cleaned properly at home, they are sent to the scourer, who has not only more skill, but greater conveniences for his business. Nevertheless, as scouring is expensive, a good deal of what is not very difficult may be easily practised with a little attention. We shall in this section treat of scouring, properly so called, where the whole of the cloth is to be cleaned, and likewise of the taking out of spots and stains.

6428. *General Principles.*—Previously to the invention of soap, which affords us so easy a mode of cleaning woven fabrics, various other materials were used. The Romans made use of certain plants and of argillaceous earths; ashes, gall, soda, and urine were likewise employed; and the Persians made use of boles and marly earths. All these materials have still a convenience, and are used in particular cases of scouring, which is, in fact, a variety of washing.

6429. With respect to taking out spots and stains, regard must be had to the nature of the cloth that is stained, and also to that of the matter which produced the spot, since it is desirable to remove the stain without affecting the original colour The most usual substances that produce stains in clothes or furniture are, 1. Fatty substances, as oil, grease, wax, &c.; 2. Resinous matters; 3. Vegetable and animal juices, as wine, fruit, &c.; 4. Iron, ink, &c.

To remove any of these matters, we must find some substance capable of dissolving them without injuring the cloth. Fat, oils, and grease are dissolved by ether, essential oil of turpentine, soap, ox-gall, and solution of alkali; or they may be absorbed by blotting paper, chalk, fullers' earth, &c. The choice of these will depend upon the nature of the cloth that is stained. Soap, or alkali, for instance, will remove grease with ease, but they will also destroy the colours of many dyed stuffs.

When stains are occasioned by acids, alkalies, or any liquids containing these, the colour of the stuff is acted upon and changed. The colour may sometimes be restored by the application of something that would have a neutralizing effect; for an acid, an alkali, and for an alkali, an acid; but this can happen only in case of the acid or alkali having been very weak. The fixed alkalies can unite with oily substances, and, by converting them into soap, render them soluble and easily washed out, but it exercises a powerful action upon wool or silk, so that it cannot be used on them, particularly the latter, except with the greatest care. The volatile alkali, ammonia, has not the same inconvenience as the fixed alkalies. When the oil, or grease, in a spot has been converted into soap by the application of an alkali, this newly-formed soap may be dissolved by spirit of wine. The absorbent earths, such as chalk, fullers' earth, and French chalk, which contains much magnesia, are employed to remove grease, where an alkali would be dangerous. Ox-gall dissolves the grease without injuring the stuffs or affecting the colours generally. To produce the desired effect better, several of these substances are sometimes mixed together to form a material for removing spots; as, for instance, soap, gall, and absorbent earth, and are called *scouring balls.* Sulphuric ether is a powerful solvent for oils and resins, and does not attack the colours, but it is so volatile, that it leaves what it has dissolved too soon. The essential oil of turpentine is, in general, the most convenient agent for combining with and dissolving oil or grease, wax and resins, while, at the same time, it does not affect the stuffs nor the colours; and the disagreeable smell it leaves may be overcome by another essence more agreeable. Some fat substances, and pitch, may be removed by blotting paper, and a hot iron to absorb them. Particular receipts will be given for each of these cases.

6430. *White silk or satin* may be cleaned thus: Dissolve some of the best curd soap in boiling water, and, when the solution is as hot as the hand can bear, pass the silk through it thoroughly, handling it gently, not to injure the texture. If there are any spots, these may be rubbed carefully till they disappear. The article must then be rinsed in lukewarm water, and dried by stretching it out with pins. If satin, the glossy or bright side must be well brushed with a clean clothes-brush, the way of the nap, till it shines; it may then be calendered; or it may be finished by dipping a soft sponge in a little isinglass dissolved in boiling water, and rubbing the wrong side of the satin, which must then be again pinned out, and again brushed and dried. Plain silks do not require brushing.

If the satin is not much soiled, the brightness may be restored by strewing on it some French chalk in powder, and then brushing it off with a hard brush; if once is not sufficient, the process may be repeated. When the silk is large, it may be laid smooth upon a board, and a little soap spread upon the dirtiest parts; then, having made a lather with fine white soap, this may be passed over the silk on one side with a brush, and then upon the other side. It must then be put into hot water, and afterward rinsed in cold water; it must next be dried and smoothed on the right side with an iron not too hot, or calendered.

If the white silks are flowered, the best method is to clean them by sifting on them some crumbs of stale bread, which must be rubbed on with the hands, and then thoroughly shaken and brushed off. If a very little powder blue be mixed with the crumbs, it will be advantageous for some shades of white.

6431. *Black silk is best cleaned* by some ox-gall put into boiling water. The silk must be laid out smooth on a table, and have both sides sponged with the gall liquor; it must then be rinsed out well in clean water. A little gum Arabic, or glue, must be dissolved in water, and passed over the wrong side of the silk with a sponge, when the silk may be stretched out with pins and dried. In many cases it is necessary to unpick the seams of articles of dress, in order to lay each piece flat upon the table.

Gall is a fluid in an animal, likewise termed bile, and is chiefly collected into a receptacle named the gall-bladder, from which it is procured. It is a liquid of a yellowish-green colour, about the consistence of thin oil, and extremely bitter. It contains a good deal of soda; hence its use in removing grease from clothes, &c. When agitated with water, it froths like soap and water; when fresh, its smell is somewhat like musk, but it very soon putrefies and becomes offensive.

6432. *Coloured silks* require a different treatment, on account of the risk of discharging the colours. For common colours, the silk may be immersed and rubbed gently in a solution of soap, as described above, and afterward rinsed in lukewarm water, taking care to be expeditious, lest remaining too long in the soap should affect the colours. More effectually to prevent this accident, the silk should afterward be immediately dipped in water slightly acidulated with oil of vitriol, if the colours are bright yellow, crimson, maroon, or scarlet; orange, fawn, or brown, of any shades, do not require such precaution. Bright scarlet requires to be dipped in water containing a few drops of a solution of muriate of tin. In cleaning silks of various colours, the water should be barely hot enough to extract the dirt, and it is better to give them a second and a third liquor than to use the water too hot. It should be observed that, without considerable skill, the colours of silks are liable to be discharged; and, upon the whole, it is safest to give these to a professed scourer.

6433. *White lace veils* are cleaned by boiling them for a quarter of an hour in a solution of white soap. They must then be gently squeezed till clean, and rinsed in warm water, and afterward in cold water, containing a drop or two of liquid blue. The veil must be starched and cleared by clapping it between the hands, and then dried on a frame, or by pinning out.

6434. *Black lace veils* are cleaned by passing them through some warm water with bullock's gall, and then rinsing in cold water. They are stiffened by dipping them into water that has a little gum or glue dissolved in it, clapped between the hands, and dried as the last.

6435. *Point lace*, if it be not very much soiled, may be cleaned by fixing it in a tent frame and rubbing it gently with crumbs of bread, afterward dusting out the crumbs. If it is necessary to wash it, fix it in the tent frame, make a warm lather of Castile soap, and dipping a soft brush in this, rub the whole gently. Afterward throw over it some clean water in which a little alum is dissolved. The wrong side is then to be gone over with some fine thin starch, and when dry, the same side must be ironed. It is to be finished by opening it with a bodkin, or otherwise it may be cleaned as directed under "Washing."

6436. *Cashmere shawls and Merinoes* may be cleaned by passing them through cold water, having in it some solution of soap in spirits of wine and purified ox-gall, and then through alum-water. They may be stretched and starched as the lace.

6437. *To clean Silk Stockings.*—Wash the stockings in lukewarm water with white soap, to get out the rough dirt; then boil them with soap and water for ten minutes, rinse them in clean water, and wash them again with fine soap, if necessary; if required to have a blue cast, put into the last water a little stone blue in a flannel bag, taking care not to give the stockings too strong a tinge of colour; if required to be of a flesh colour, a little rose pink will do. Dry them, and, to smooth them, put them on wooden legs, two at a time, one over the other, observing that the outsides are face to face; then polish them with a glass, or send them to be calendered or mangled.

6438. *To scour Wool.*—Wool in its natural state is covered with a kind of grease called the yolk, which, as it is found to preserve it from insects or moths, is not removed by scouring till it is to be dyed or spun. The process for scouring wool is this: the wool is put for about a quarter of an hour into a kettle of water, to which some soap or alkali, or, what is better, about a fourth of stale urine, has been added. It is then heated to 140°, occasionally stirred, and, being taken out, is allowed to drain. It is next put into a basket and exposed to a stream of running water, and moved about till the grease is so completely separated that it no longer renders the water turbid. If the wool is intended for dyeing, this process must be very carefully performed. The mode in which the urine acts in scouring is explained thus: urine, left to itself for a few days, is found to contain a portion of the volatile alkali, or ammonia; this combines with the oil in the wool, and forms a soap, which, being soluble in water, is dissolved and carried off. When wool is required to be perfectly white for dyeing, it is sulphurized; and the harsh feel given by this is removed by washing with soap.

6439. *The scouring of blankets* being heavy work, the instrument called a *dolly*, or maid, is sometimes employed to lessen the manual labour in beating and wringing them (see *fig.* 834). Its use is to beat the blankets, counterpanes, and such heavy articles, in the tub with water and soap to clean them. To prepare the water for scouring, cut a pound of mottled or of yellow soap into thin slices, and dissolve it in a gallon of boiling water, adding an ounce of pearlash or of soda. When the soap is quite dissolved, mix the solution with a quantity of cold water, to make it only so hot that the hand can bear it. Put this with the blanket into the scouring tub, which must have a very strong or double bottom, and beat it with the doll, turning it frequently. After it is thoroughly cleaned, the next operation is to wring out the soap and water. This being difficult to do by the hands alone, may be assisted by hanging up the blanket till the two ends meet, and, fixing this to a hook in the wall, pass a short thick stick through the fold; by means of this the blanket can be twisted and wrung out very hard.

In London, blankets are usually sent to the scourers, few town houses having sufficient convenience for this business to be performed at home. But laundresses sometimes undertake them.

6440. *A counterpane* may be scoured in the same manner. If the colour is bad, it will be necessary to boil it in a copper, and in beating it with the dolly to add a little liquid blue.

6441. *Black, blue, and brown wollen cloths* require a different process. The greasy spots must first be plastered over with a paste made with fullers' earth and boiling water, and these places must be dried by the fire or the sun. A little ox-gall must now be mixed with stale urine, adding a little boiling water, still taking care not to reduce the strength too much. Dip a hard brush in this, and brush well the spots which had the fullers' earth, and any other places that may require it. Immerse now the whole cloth in cold water, wash off the dirt, and hang it up to dry. When it is nearly dry, brush the nap of the cloth the right way, and to bring on a gloss, pour a very little olive oil in the hand, and passing the brush over it, brush the cloth over carefully and evenly.

6442. *Cloth of all other colours*, except scarlet, may be cleaned by rubbing the greasy spots with a ball of yellow soap, and when this is nearly dry, brushing off the soap with warm water. If once is not found sufficient, the process may be repeated.

6443. Scarlet cloth requires peculiar care in scouring, as the dye is liable to be discharged. If the cloth is not much soiled, it may be cleaned by washing it in bran water, made by pouring boiling water on bran placed on a hair sieve, adding to the liquor a little white tartar; the process may be repeated, if necessary. If the colour begins to discharge, a drop or two of the solution of muriate of tin must be added to a second liquor of the same kind, and the cloth be kept immersed in it for ten minutes, and then be wrung out and dried. If the scarlet cloth is much soiled, the worst parts must be brushed with soap dissolved in warm water, or the whole must be dipped in strong soap and water, and rubbed quickly; but as soon as the colour begins to give, it must be removed and rinsed out in warm water into which some muriate of tin has been put; after remaining in this for ten minutes, it should be dried in the shade, in a warm room; it may then be cold-pressed.

6444. *In London, in which there are professed scourers*, window-curtains of *moreen* are generally given to them to clean, if the colour is not too faded. They usually charge about sixpence per yard; if watered, about two-pence more.

6445. *Carpets and hearth-rugs may be cleaned in the following manner:* If they are very dirty, they are perhaps best sent to the scourers; but if not, after being well beaten, they are to be laid down, and all the spots of grease removed by laying on them a hot paste of fullers' earth, and next day, when it is dry, brushing it off. The whole of the carpet must now be rubbed over, a piece at a time, with a flannel on which soap has been rubbed, wetted in water that has a little soda dissolved in it, and as soon as a part is thus cleaned, the soap must be removed by another clean flannel, and plenty of clean warm water. Some prefer ox-gall instead of soap, or mixed with the soap, as less likely to injure the colours, using more gall with the water where the spots are worst. Lastly, the carpet must be finished by rubbing with a clean, dry flannel, and dried thoroughly by setting the windows open to remove the smell. If the carpet is very dirty, and not valuable, it may be scoured as a blanket, and beaten with a doll, though this is apt to injure some colours. Professed scourers have a large scouring-board, across which they draw the carpet, to get at it more conveniently; and they rub the dirtiest parts with a piece of soap dipped in boiling water.

6446. *The following receipt for the same purpose* has been given in the "Workwoman's Guide:" Dissolve an ounce and a half of alum in a quart of warm water; also one ounce and a half of fullers' earth in another quart of warm water; put a little of each into a bucket full of soft water, adding a very little gall, and rubbing in some common brown soap. Then wash a small piece of the carpet with a flannel dipped in this mixture, so as to make it rather wet; and, to show the colour, brush it over with soap, which must be well washed off, and the carpet rubbed over with a coarse cloth. Then wash it over with soap and water in which gall, alum, and fullers' earth are mixed, and rub it as dry as possible with a cloth. When the whole carpet is washed over in this manner, piece by piece, it will appear as fresh and bright as a new one. The quantities here given are enough for a large carpet.

Another Way.—Boil some bran in water, and with this wash the carpet with a flannel and brush, using fullers' earth for the worst parts. When dry, the carpet must be well beaten to get out the fullers' earth, then washed over with a weak solution of alum to brighten the colours.

6447. *To clean coach-linings of cloth*, or coarse cloth of any kind, dip a brush in warm gall, and go over the greasy parts ; this will dissolve the grease, and the parts may be rinsed in cold water. Having dried the cloth, take fine sand a little damped, and strew it over ; then beat the sand in with a brush, and brush it off again.

6448. *Clothes powder, for cleaning cloth or cassimer of every kind,* is useful to travellers. It is made by mixing a pound and a half of pipe-clay, an ounce of starch, and two ounces of spirits of wine. Each article should be powdered separately very fine, and the whole mixed together, adding the spirits, a few drops at a time, and breaking the knots ; pack it, when made, in boxes for travelling. An ounce of white pepper added will keep away moths. To use it, sprinkle a small quantity of the powder on the cloth, and rub it in with the hand, then brush the powder out with a clothes-brush. Should there be any spots of grease, put a little of the powder on them with boiling water, and let it lay on till dry, then brush it off.

6449. *Of printed cottons,* some will bear washing in the ordinary way with soap ; others will not, without the colours being injured. This depends upon the processes employed in the printing. When they are washed, it is recommended to add twenty drops of oil of vitriol to the gallon of water in which they are dipped after rinsing, to preserve the colours.

6450. *Chints bed and window furniture,* when not very dirty, may be safely cleaned in the Oriental manner, by using rice water. Boil two pounds of rice in a gallon and a half of water ; when the rice is soft, rub it upon the chints as if it was soap, and wash it in the rice water. Then strain the rice from the water, and wash again till the chints is quite clean. Rinse the cloth, dry, and instead of ironing it, glaze it with a polishing stone, or have it calendered or mangled. The rice water serves instead of starch. If the rods or grooves of the chints be disturbed by this washing, twenty drops of sulphuric acid should be put into the gallon of water before the chints is wrung out, which must be done very gently. It is, of course, necessary to take all chints hangings to pieces, and to separate the fringe bindings and linings, before they are washed. The linings may require to be re-dyed. In London, chints hangings are usually sent to the dyer's.

If the chints is very dirty, it may be scoured with ox-gall and water, which will not injure the colours.

6451. *A method of cleaning silks, stuffs, moreens, printed cottons, or chintses, by the use of potatoes, without injuring the colours,* is described in the "Transactions of the Society of Arts for 1805." Grate raw potatoes, washed and peeled, to a fine pulp ; add water in the proportion of a pint to a pound of potatoes ; pass the liquid through a coarse sieve into a vessel, where it is to remain till the fine white starch subsides to the bottom. Pour off the clear mucilaginous liquor, which is to be used for cleaning. To perform this process, spread the article to be cleaned upon a table, which should be covered with a linen cloth ; dip a sponge in the potato liquor, and apply it till the dirt is removed ; then wash the cloth in clean water several times. The coarse pulp which does not pass the sieve will do to clean worsted curtains, carpets, or other coarse furniture ; and the white starch that subsides may be employed for starching, or instead of arrow-root. Some use the whole of the pulp and water for the scouring ; and others slice the potatoes, and rub them on the stuff as if it was soap.

6452. *To remove spots of Grease from Woollen Cloth, Silk, Cotton, or Linen.*—If the articles will bear washing this will remove it, particularly if the spot be touched with a little alkali ; but if washing cannot be employed, the following methods will be effectual Some absorbing substance may be used, as fullers' earth, or tobacco-pipe clay, of which the first is the best. These earths, melted, must be laid upon the spots, and as the water evaporates the oil will be absorbed, and leave the fibres of cloth ; then, when dry, the earth may be brushed out. A little sulphuric ether may sometimes be necessary to remove the stain completely, and this, again, may be washed out with spirits of wine ; or the following compositions, wetted, may be laid on the cloth. Take an ounce of pipe clay, and grind it with twelve drops of turpentine and twelve of spirits of wine. When dry, the composition must be rubbed and brushed off, when the stains will disappear.

Another Method.—Rub a little magnesia, moistened, on the spot. When dry, brush it off, and the stain will have disappeared.

Grease spots in cloth may also be removed by using soap and water and a nail brush, and afterward wiping off the lather with a wet towel. French chalk may also be used for the same purpose, thus : Cover the spots with scraped French chalk ; place these parts on a water plate containing boiling water, or on the face of a warm iron. This will melt the grease, and the French chalk will absorb it, and the whole may then be removed by brushing. If once is not sufficient, repeat the process ; or the French chalk may be mixed with lavender water, or with turpentine, so as to make a paste, which is to be put upon the stain ; over this lay a piece of blotting-paper, and run it over with a hot iron : then brush off the chalk.

6453. *An excellent method of removing spots of grease from silk or cotton dresses* without hurting the colour is the following : Grate raw potatoes into water, so as to form a pulp ; pass the liquid through a sieve into another vessel of water, and let the potato subside. Pour the clear liquor from the top, which may be bottled for use. Dip a sponge or a small brush in this, and wet the spot till it disappears ; then wash it in clean water. Be very careful not to wet more than the spot, as there is danger of discharging the colour. Spirits of turpentine is, perhaps, the safest thing for this purpose; apply this with a bit of sponge, and rub it with a clean linen rag; the turpentine will dissolve the grease, and the rag will absorb it. A little essence of lemons will correct the smell of the turpentine.

6454. *Scouring drops*, which are made of equal quantities of oil of turpentine and essence of lemon, are sold for taking out stains and grease from silk. They are rubbed on with a bit of flannel, and generally answer perfectly well.

6455. *Scouring balls, for taking spots of grease from cloth or silk*, are likewise convenient. They are made thus: Take pipe-clay, two pounds; fullers' earth and whiting, each four ounces; ox-gall, a quarter of a pint. Powder the whole, and mix the gall with these, stirring and bruising them, so as to compose a stiff paste, which is to be made into the form of rolls, balls, or any other convenient shape. To use them, rub the ball over the soiled part, until it is well covered; then rub it briskly between the hands, and brush out the dust with a clothes-brush: if once is not enough, repeat the operation several times. Any part that is very greasy may be treated by scraping a little of the composition and putting it on with hot water, and when dry, brushing it off. If required to be quite white, the fullers' earth may be omitted, and whiting used in its stead; they do not injure any coloured cloth; or they may be made by mixing eight ounces of white soap, an ounce of oil of turpentine, two ounces of ox-gall, one drachm of lemon-juice, and eight ounces of starch powder.

6456. *Rolls may also be made for removing grease from silk* as follows: Mix an ounce of pounded French chalk with five ounces of pipe clay, and add to this two ounces of spirits of wine. Form this paste into rolls of the size of one's finger. When dry, they may be applied to silk or stuffs to remove grease, in the same way as the balls above described were to woollen cloth; and the stuff must be afterward washed with cold water.

6457. *To remove Oil or Grease from Boards.*—Moisten fullers' earth with hot water, and let it stand till it is cold; then spread a thick plaster of this over the spots: let it remain on all night; next day scour the place with hot water. If necessary, repeat the process.

6458. *To remove spots of wax* from clothes, moisten them repeatedly with strong spirits of wine; this will so far dissolve the wax that it will become dry and brittle, and may then be brushed off; or a few drops of rectified turpentine may be employed as still more effectual; and the turpentine may be washed out with soap and water.

6459. *Balls for cleaning chamois leather* are made by pounding and mixing together one pound of Bath brick, four ounces pumice-stone, two pounds pipe clay, and half a pint of ox-gall. If a yellow colour is required, add sufficient yellow ochre. They are used as the balls last described.

6460. *To take out Spots of Oil Paint from Clothes.*—The paint may be removed before it becomes dry and hard, by brushing the part with soap and water, or more effectually by turpentine; but after the paint has become dry and hard, soap will not remove it. The spot should then be touched with turpentine applied with a pointed stick; this should remain for some time, till the turpentine has dissolved the hardened oil and loosened the paint. When the place is dry, it may be rubbed between the fingers, and the colour will crumble off in loose powder. The smell of the turpentine will go off in a day or two, but may be removed sooner by laying a piece of brown paper on it, and applying a hot iron, or by spirits of wine.

6461. Pitch or tar must be removed by spirits of turpentine, either from cloth or from the hands.

6462. *Recent stains of ink* may be nearly removed if, before the ink is dry, the places be washed with plenty of water after a sponge has been used, to take up as much of the ink as possible; if this does not succeed, rub the part with lemon juice, tartaric acid, or purified wood vinegar, and after that wash it with soap and water.

6463. *To remove Spots or Stains of Ink which have dried, and Iron Moulds.*—The black colour of ink is owing to red oxyde of iron united to a principle existing in all barks, called gallic acid; and iron moulds are the red stains of iron, owing to the red oxyde of iron which is left by itself, from ink, or from contact with rust of iron. Whatever dissolves the iron will destroy the iron mould; acids have this effect, but if they are too strong, they likewise corrode the linen. Certain weak acids, which have a strong affinity for iron, are selected for this purpose, the best of which is the citric acid, or the acid found naturally in the citron, in limes, in lemons, and other fruits. On account of its having been procured plentifully from lemons, it is sometimes called *salt of lemons*, or crystallized lemon juice. For a more particular account of it, we refer the reader to our description of the lemon among "Fruits," Chap. IX., Book VII.

Another acid which has the same effect, and which is now more used, from being cheaper, is the *oxalic acid*, which, it is proper to know, is a deadly poison. This acid exists naturally in wood sorrel; though in this plant it does not exist pure, but combined with potash, forming oxalate of potash, which is also poisonous. The leaves of wood sorrel, which contain in their grain this oxalate of potash, when bruised and rubbed upon iron moulds, removes them; but as a more convenient mode, this salt has been extracted from sorrel and is sold for this purpose, under the very improper name of salt of lemons.

6464. *The method of taking out iron moulds with salt of lemons*, whether the genuine or the fictitious (the salt of sorrel or oxalate of potash), is this: A small quantity of the salt is pounded and applied on the spot; and then some hot water is dropped on it, and rubbed in, upon a pewter plate placed upon a stove, or on a water plate containing boiling water; the acid dissolves the iron in the iron mould or the ink, and a little warm water washes all out. If one is not enough it must be done over again. The rationale of this effect is, that the oxalic acid has a greater affinity for iron, whether in the ink or in the state of iron mould. It unites, therefore, to the iron, leaving the potash, and forming an oxalate of iron, which salt is colourless, and being soluble, is easily washed away. The method of making the salt of sorrel from the juice of the plant has been described in our account of "Sorrel," Chap. IX., Book VII. If the stains are of long standing, and difficult to remove, the spots may be wetted for five minutes with sulphuret of potash or muriate of tin, and after this is washed out, applying the citric acid.

Iron moulds may likewise be removed by the bleaching liquid to be described.

6465. *Stains from vegetable substances, as fruit, wine, &c.*, may be removed by simple washing, if that can be done before the stain is dry; but after that the colouring matter adheres with more force, and is sometimes difficult to remove. If the stain be recent, it may be destroyed sometimes by rubbing on a little alkali, as soda or pearlash; but a mixture of ammonia and spirits of wine is safer; the spots should be soaked in it some time. Some faint stains left may be destroyed by moistening the cloth and holding the spot, at a due distance, over the fumes of a brimstone match.

Some recommend putting salt upon the part as soon as the accident has happened; and probably the stain may come out in the washing. Rubbing on the stained part immediately soap and whiting is also recommended; after which it must be well bleached in the air. Some stains may be removed by sour butter-milk.

6466. *If the fruit stains have been long in*, rub the part on each side with yellow soap, then put on thick starch in cold water and rub it well in; hang the linen in the air, exposed to the sun for three or four days, and, if that is not sufficient, repeat the process.

6467. *The most effectual thing for removing stains of all kinds, except those from grease, is the bleaching liquid.* This is sold for the purpose under that name, but as the price is considerable, we shall show how it may be procured at a cheaper rate. The powder called chloride of lime (for the nature of which, see "Bleaching") is sold, and may be bought for 6*d*. a pound. To make a solution in water, which constitutes the bleaching liquid, put four ounces into a wide-mouthed quart bottle, add to it a little water, and stir this together with a stick; then fill the bottle nearly full with water, and let the whole stand together corked for about a fortnight, that the chloride may dissolve. During this time, some gas will be disengaged, and to prevent this driving out the cork, twice a day it will be well to take out the cork for an instant only; and it is to be noticed that the gas has an extremely offensive, suffocating smell, and that it must by no means be suffered to get into the lungs, or it will cause excessive coughing; though when diffused through the apartment in such small quantity it is not hurtful. At the end of the fortnight the clear solution is to be poured off, and kept in a well-corked bottle, with paper wrapped round the bottle, in a dark place, for light or air injures its properties. This solution, or bleaching liquid, when diluted with water, will remove any stains from linen by keeping the part some time wetted with it; but it has no effect upon grease or oil.

6468. *If neither the bleaching liquid nor the chloride of lime can be procured*, chlorine itself may be formed thus; and it will have the same effect: Into a large tumbler put one drachm of black oxyde of manganese finely powdered; this may be had at most of the druggists'; add to it three drachms of common salt. Pour upon this mixture two drachms of oil of vitriol; a thick greenish vapour will immediately appear, which is the chlorine gas, set loose from the salt; and it is this gas that has the peculiar property of destroying colours, and, consequently, of removing stains, as is explained under "Bleaching." The fabric that has been stained must now be wetted, and held tight over the top of the tumbler, that it may come in contact with the gas, which will very soon cause the stain to disappear. But this can only answer for textures that are white; for if coloured ones, it will remove the colour, together with the stain, in which the remedy would be as bad as the evil. It is necessary to observe that, whenever the bleaching liquid or the chlorine gas is applied, the linen must be *immediately* very well washed and rinsed afterward; since if this should be neglected, its texture would be rotted or much weakened; but if employed with proper precautions, they are as safe as soda or pearlash. The bleaching liquid is safer than the chlorine gas.

6469. *An extemporaneous bleaching liquid* may be thus made: Put a few grains of the chlorate of potash (a salt kept by most chemists and druggists) into a tea-spoonful of common salt, and dilute it with water.

6470. *To remove Mildew from Linen.*—Moisten a piece of soap, and rub it on the parts affected. Then rub over the parts with whiting; lay the linen on the grass, and from time to time, as it becomes dry, wet it a little.

6471. *To restore the nap* in places where clothes have been worn threadbare, a process may be occasionally resorted to which is employed by dealers in old clothes. They soak the cloth in cold water for half an hour, and then, having laid it upon a smooth board, they raise the nap by rubbing it with a thistle called a teazle, used by manufacturers of cloth. The nap is then brushed in one direction to lay it.

6472. *To raise the Pile of Velvet when pressed down.*—Warm a smoothing-iron moderately, and cover it with a wet cloth, and hold it under the velvet; the steam or vapour rising from the heated cloth will penetrate through the velvet, and enable a rush whisk to raise the pile.

6473. *To sulphur Silks, Woollens, Straw Bonnets,* &c.—The fumes of sulphur, consisting of the sulphureous acid gas, have a powerful effect in destroying colour; and are, therefore, much employed in whitening various substances. The way of managing it is as follows: Provide a large box or cask to hang the clothes in, and on the bottom of the box place a small chafing-dish with some lighted charcoal; upon this strew some brimstone, and cover up the box close, leaving the things to hang for several hours.

6474. *To clean white, brown, or fawn-coloured Feathers.*—Dissolve some fine white soap in boiling soft water, and add a small bit of pearlash. When the water is just cold enough for the hand to bear it, pass the feathers several times through it, squeezing them gently with the hand. Repeat the same process with a weaker solution of soap, and then rinse the feathers in cold water, beating across the left hand for about ten minutes, to expel the water; when they are nearly dry, draw each fibre or flue over the edge of a small blunt knife, turning it round in the direction you want the curl to go; then, if the feather is to be flat, put it between the leaves of a book to press it.

6475. *Black feathers* may be cleaned with water and some gall, proceeding as with the last.

6476. *Wash-leather gloves*, as their name implies, may be easily washed with soap and water; when nearly dry, the fingers should be stretched with a piece of wood.

6477. *White and coloured kid gloves* are more difficult to clean; but it is said they may be cleaned perfectly by laying them on a clean towel, rubbing them with a piece of flannel dipped in a hot, strong lather of white soap, till the dirt is removed, using as little water as possible. Hang them up at a distance from the fire to dry gradually, and after they are quite dry, pull out the shrivels and stretch them on the hand.

BOOK XXIII.

CARRIAGES.

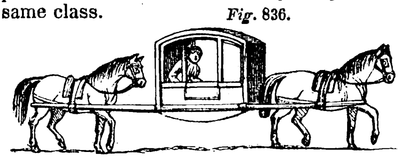
CHAPTER I.

HISTORY OF CARRIAGES.

6478. No nation entirely in a savage state is possessed of any vehicle such as we denominate *a carriage;* and mankind must have advanced somewhat considerably in civilization before they subjected animals so far as to domesticate them for the purpose of drawing wheel-carriages. The Esquimaux have trained dogs to draw their sledges, and the North American Indians use horses for riding, an art introduced by the Spaniards. Besides these, asses, mules, lamas, camels, dromedaries, elephants, and even the bull and cow, have been used in various countries for draught, though the origin of their substitution for human power cannot be traced. Of these, the horse, the ass, and the mule are found the most generally useful; the camel and dromedary are preferred by the Arabian only when he crosses the sandy desert, on account of their being able to subsist long without drink. Among the Indians of Peru the lama is the common beast of burden; and in other countries, as Iceland, the horse is the sole means of conveyance from place to place, and to carry provisions and merchandise.

In crossing steep and rocky mountains, impracticable for carriages, or even for horses or mules, such as parts of the Andes of America, travellers are carried in a chair on men's backs; in China, one of the best modes of travelling is in a sedan, carried by two men on elastic poles, connected at the ends; and the same method is used in some parts of Brazil. In India, the palanquin is a more luxurious kind of conveyance of the same class.

Fig. 836.

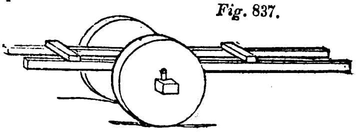


6479. *The ancient litter, fig.* 836, was a kind of vehicle borne by men upon shafts, in the manner of the palanquin. It was much used among the Romans; and Pliny calls it the traveller's chamber, the name *lectica* having probably been derived from *lectus*, a bed, there being usually a pillow and a quilt within. In the time of Tiberius, these were in common use, as we learn from Seneca. The litter was also sometimes conveyed by horses; and the horse litter, which was introduced into Rome from Bithynia, was first brought to this country by the Normans; it is still used by the pope on certain state occasions, and also by travellers in the mountain passes in Sicily, Spain, and Portugal. For several reigns succeeding the Norman conquest, these were the only carriages employed in England for travelling by opulent persons; and this vehicle was used as a conveyance even long after the introduction of coaches, being the easiest, and giving least fatigue of any then known. The mother of Charles I.'s queen entered London in a litter after having travelled from Warwick in a coach.

6480. *Previous to the invention of wheels, the sledge* was no doubt long in use. The facility with which a log of wood can be dragged would suggest the idea; and in northern countries the sledge is constantly employed, in the present day, when the ground is covered with frozen snow. In Madeira, the heavy pipes of wine are drawn on sledges from the mountain vineyards to the coast, and a person accompanies them to wet the bare rocks with a mop, to diminish the friction. A similar instance is the sledge loaded with barrels employed by the London brewers, and drawn by a single horse. In Wales, sledges are used to draw hay and corn; but in all sledges on dry ground the friction is considerable.

6481. *Wheel carriages are of great antiquity*, being mentioned in the history of Joseph when among the Egyptians; and drawings from ancient representations of Egyptian chariots have lately been published. Indeed, the discovery of the wheel could not be long after the practice of moving logs or trunks of trees by means of the lever. Heavy stones were likewise moved, in ancient times, upon rollers.

Fig. 837.



The first wheels were probably solid cylinders (*fig.* 837), which would afterward be lightened by connecting together by a beam or axle two slices cut off a tree; and two poles joined by cross-pieces laid upon this axle would form the simplest carriage. The next improvement would be rounding the axle (*fig.* 838, *a*) and making the solid wheels revolve upon it; and a frame of wood-work, with a handle to draw it by, was probably the first wheel carriage. Nearly such a vehicle may still be seen in the hands of the modern mason. The antique car used in war by the Egyptians and Greeks was equally simple; the wheels were small, but perforated to give them lightness (*b*, *fig.* 838), the warrior standing in the carriage. A box, or basket, placed upon the axle, makes the rude cart; and the construction of the wheels in the present mode, of naves, spokes, and felloes, is another advance towards perfection, which not only admits of their being of larger size, but causes them to be more durable, by a metal band all round the circumference.

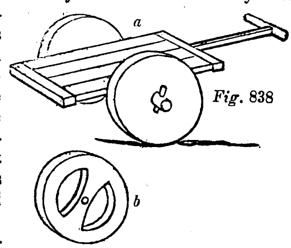


Fig. 838

But two-wheeled carriages would be found inconvenient for moving heavy loads, because part of the load must be supported by the power employed for the draught, whether men or animals. This would give rise to the use of four wheels, by which the whole weight would be on the carriage, and the power of draught only required; with this view, at first, no doubt, all the wheels were of equal size, like those on our railroads, and such was, probably, long the construction of four-wheeled carriages.

6482. *Though Beckmann, in his History of Inventions, has taken considerable pains to prove that covered carriages* for travelling and pleasure, under different forms and denominations, were used among the principal nations of antiquity, yet the earliest mention of them in modern Europe is towards the end of the thirteenth century. During the feudal times, it was the fashion for the lord to appear on his courser, and the fine dames sat gracefully upon their palfreys; but when Charles of Anjou entered Normandy, his queen appeared in a *caretta*, highly ornamented with velvet and gold. The French *charette* was the same kind of ornamented and covered cart; it is mentioned by Chaucer as having been introduced into England; and probably it had no springs. Various contrivances of this kind appear to have been employed, either for invalids or as a luxury, although the accounts of them are extremely imperfect. Hungary is the reputed birthplace of the proper coach, and, according to some, received its appellation from *Kotsee*, a Hungarian village, where it was first invented. In 1294, Philip the Fair forbade the use of these vehicles to citizens' wives; and in the reign of Edward III. of England, although they were not uncommon, it was long considered as effeminate to ride in a coach. Various kinds of vehicles no longer known were, however, used formerly in this country by the middle classes; and at tournaments they were objects of great display.

6483. *About the beginning of the sixteenth century coaches became extremely numerous* among the nobility on the Continent, and frequently consisted of a carriage having pillars supporting a canopy with curtains, to which, ultimately, glass succeeded. Stowe informs us that coaches were not used in England till 1555, when the first was made for the Earl of Rutland; and in 1564 one was constructed for Queen Mary. Queen Elizabeth had been on the throne seven years before she had a coach, but she used frequently to travel in one during her progresses; before that time, she used frequently to ride behind her lord-chamberlain on horseback. Since that time coaches have been in constant use.

6484. Mr. Adam, in his interesting work on Wheel Carriages, has described a vehicle contrived in France in the reign of Louis XIII., and brought into general use in Paris. It was named a *brouette*, or *roulette*, and was in the form of a sedan chair, placed or suspended between two large wheels, in such a manner that the bottom of the body was within a foot of the ground, and it was drawn by two men. This mode of hanging the carriage may have partly suggested the form of our present hackney cabs.

6485. About 1624, *sedan chairs* were introduced into England by Sir S. Duncombe, who was a great traveller, and had seen them at Sedan; these were long a rival to coaches.

6486. *The addition of springs to carriages*, with a view to prevent the jolting which occurs in passing over rough roads, is, comparatively, a late improvement. Before steel springs were invented for this purpose, the bodies of the four-wheeled carriages of Europe for travelling were suspended by long ropes or thongs placed beneath, which were fixed to the frame with wheels; and the seats were suspended on straps, somewhat in the manner in which we still see occasionally light butchers' carts in the country parts of England. In countries where the roads are very bad, springs can scarcely be used, being liable to break, and repairing them on the spot being generally impossible; but the inconvenience of the necessarily long leathern straps by which the bodies were hung would naturally lead, in time, to interposing some kind of spring between the body and the carriage to break the concussion, and elastic wood was first resorted to. This was applied in various ways, until the superiority of springs made of steel became evident, and the improvements in roads permitted their adoption.

CHAPTER II.

CONSTRUCTION OF FOUR-WHEELED CARRIAGES.

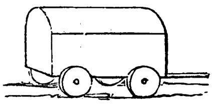
6487. *The construction of modern carriages is far from being simple or obvious to persons in general* who have not paid particular attention to them; indeed, we believe that few persons will be found, even among those who keep carriages, who have correct ideas respecting their construction and mode of action; as, for example, in what manner a four-wheeled vehicle is enabled to turn. On this account, and likewise because this interesting subject has not hitherto been treated of satisfactorily in any popular work, we have considered it desirable to explain the leading principles on which wheel carriages in general are constructed, a branch of knowledge highly useful to all who have to choose such vehicles for their own use; and we shall likewise point out the distinctions between the various carriages at present in fashion, but confining ourselves to those used for pleasure and convenience, and drawn by horses, omitting steam-carriages and all vehicles for transporting goods, as carts, wagons, &c.

6488. *Less than half a century ago the variety of carriages was very limited;* but these have multiplied so much of late years, that an enumeration, or even a distinct classification of them, has become difficult. Besides our native constructions, a few foreign kinds have been introduced, which have been submitted to the alterations of our coachmakers to adapt them the better to English habits. As it is now the custom much to consult the particular wishes and tastes of the possessors, coach-builders have departed from the trammels of ancient forms, and are continually producing new varieties, which cannot be easily classed; and the former names having been still, in a great measure, retained, with some modification, great confusion has taken place in the nomenclature of carriages. Among those which have been so remarkably altered, the phaetons may be cited as an example, and carriages termed phaetons are exceedingly unlike each other. This is endeavoured to be corrected by some addition to the name, as cab phaeton, britzschka phaeton, &c.; but it would be impossible to lay down any rule by which an inexperienced person could name or class the different carriages now in use. In some cases the new carriage has been named after the inventor, as the Tilbury and Stanhope.

6489. *Carriages are divided into four-wheeled and two-wheeled*, each of which forms a class that requires to be considered separately; and although the latter is the simplest, yet we prefer commencing with the first, as containing the greatest number of parts, many of which are common to both classes.

6490. *The most simple kind of four-wheeled carriage* is that which was probably of the original construction, a large open box, or a covered chamber placed upon two fixed axels, having wheels on each end, in a similar manner to some of those first used on the railroads (*fig.* 839). But the construction at present of carriages for pleasure, which are drawn by horses, is much more complicated; and to explain the origin and nature of their structure requires that we should enter into some previous details. When four-wheeled carriages were first used in the simple form we have mentioned, it would be found that they would go perfectly well upon straight roads, or where there was very little bend; but that it would be difficult to make them turn in a confined space, because, while turning, both axles being fixed, the fore wheels would partly drag along the ground, instead of revolving like the hind weels. This inconvenience is now obviated by a very ingenious contrivance, which is adopted in all four-wheeled vehicles.

Fig. 839.



6491. *Although, in common language, the term carriage is applied to the whole vehicle,* yet, among coach-makers, it is more limited in its application; according to them, the vehicle consists of two parts, the *body* and the *carriage;* the first being the receptacle for the passengers, and the second the system of frame-work with the wheels, to which the body is fixed or suspended. The carriage part is also divided into two, called the *upper* and *under carriage*, these being separate and distinct framings. The upper carriage or framing remains either attached to the body, *a a* (see *fig.* 840, which represents the under side), or, at least, always remains in the same relative position with respect to it, and it contains the hind axle, with its two wheels, *b b*. But the under carriage or framing, which contains the axle with the fore wheels, *c c*, is so contrived that it is moveable on a centre, *d*, into oblique positions, the use of which is, that, being by its moveable property always at right angles to the direction of the road, represented by the dotted lines, its wheels can revolve instead of dragging along the ground, as they must have done if fixed to the body like the hind ones. Thus, though both axles are parallel while moving forward in a straight line, they are no longer so while the carriage is turning. The fore wheels may be considered as the conductor of the carriage, and their axle is turned by means of a long, horizontal lever attached to it, called the *pole*, passing between the horses. This turning of the fore axle is termed "*locking*."

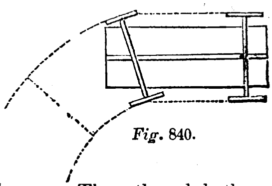


Fig. 840.

If the body be considered as a large open box, having the hind axle fixed on the under side, and the fore axle turning on a pin in its centre, we shall have the construction of the ordinary four-wheeled carts, and perhaps of the most ancient carriages. But the introduction of the present manner of hanging the body by straps or braces, to lessen the concussion from rough roads, caused the carriage part to be detached from the body, and the hind and fore axles, with their wheels, to be connected together, not by the body, but by a separate long piece of wood or iron, *d e*, called the *perch* of the carriage. The under carriage turns upon a pin, called the *perch bolt*, passing through it and the perch, thus connecting them together, while the perch is fixed immoveably to the hind axle. The two axles with the perch now become the proper carriage part, and, if detached from the body, may be drawn together alone by the horses, as may be frequently seen when repairs or alterations are being made, and in breaks for horses. This construction, however, of an upper and an under carriage, though productive of so much advantage in turning, has given rise also to some imperfections. It is obvious that if the body be as long as the distance between the axles, when the fore axle is turned into an oblique position, it will come into contact with it, and be prevented from moving farther round, except the body be placed so high that all the wheels may pass beneath it; but this great elevation of the centre of gravity would be unsafe and inconvenient, and has led to making the fore wheels smaller than the hind ones, that they alone may pass beneath the body in turning; or that the body should be modified so that the fore wheels shall not interfere with it, which is sometimes effected by cutting away a portion of the front under part, called by the coach-makers, technically, a "step piece." These considerations have been the occasion of the custom that has long been universal, of making the fore and hind wheels of carriages of different sizes; and some have erroneously imagined that a mechanical advantage has been thus obtained; whereas, on the contrary, the fore wheels, being smaller than the hind ones, lose somewhat of leverage, and, besides being obliged to make more revolutions in the same time than the hind ones, have increased friction, and wear out sooner; but, notwithstanding these defects, the great accommodation in turning has caused the practice to be continued.

6492. *Having now given the simplest idea of the principles by which a modern four-wheeled carriage is enabled to turn easily,* and which is essential to its perfection, we shall proceed to describe the actual structure of the carriage of a coach, as this will enable the reader to understand more clearly that of any other travelling wheel vehicle.

6493. *Figs.* 841, 842, 843, 844, represent the plans and elevation of the carriage part of a coach. *Fig.* 841 is the plan of the carriage part, in which the upper carriage is drawn in full lines, and the under carriage in dotted lines. For the convenience of reference, the same letters are attached to the corresponding parts in all the figures 841, 842, 843, 844.

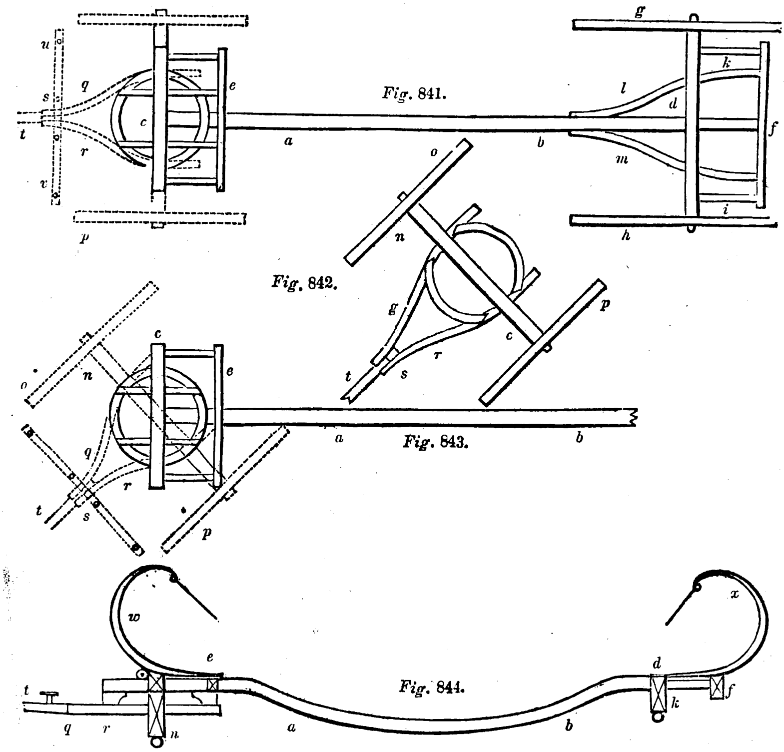

Fig. 841. *Fig.* 842. *Fig.* 843. *Fig.* 844.

To begin with the plan of the upper carriage: *a b* is the *perch*, which, as seen in the elevation, *fig.* 844, is of the curved kind. It is framed into a cross-piece, *c*, called the *fore transom*, in the fore part, and into another cross-piece, *d*, called the *hind axle bed*, which is a strong piece of wood, in the under side of which the hind axle of iron is bedded, carrying the hind wheels, *g* and *h*, *fig.* 841. To complete the description of the hind part of the carriage, we may point out another cross-piece, *f*, called the *hind transom*, or *hind spring bar*, connected with the hind axle bed, *d*, by short pieces, *i* and *k*, *fig.* 841, called *nunters*. Two curved-spreading pieces, *l* and *m*, called *wings*, cross these, and are fixed to the perch. In the fore part of the upper carriage, besides the fore transom *c*, already mentioned, there is another cross-piece, *e*, called the *horn bar*, connected with the fore transom by short pieces. To comprehend the under carriage, the reader must imagine a very strong piece of timber lying beneath the fore transom and the perch, the ends of which are seen projecting in dotted lines beyond, carrying the fore wheels *o* and *p*, *fig.* 841, but which appears distinctly in *fig.* 844, where it is marked *n*, and also in an oblique position, *n*, *figs.* 842 and 843, which represent the fore axle in the act of turning. An iron pin, called the *perch bolt*, passes down through the fore transom and the fore axle bed, thus connecting together the under and upper carriages, and enabling the fore axle to turn on it as a centre, as is represented in *figs.* 842 and 843, which is the contrivance to make the carriage turn already spoken of. To render the nature of the under carriage more evident, it is represented not only in the dotted lines in *figs.* 841 and 843, but by itself, and without the upper one, in *fig.* 842.

To enable the horses to turn the fore axle *c*, two curved pieces, *q* and *r*, called *futchels*, are framed into the fore axle bed, and are united together at *s*, called the *chops of the futchel*, between which the pole, *t*, that passes between the horses, is inserted: *u* and *v*, *fig.* 841, is the *splinter bar*, fixed upon the futchels, to the roller bolts of which the traces are attached, to draw the carriage by.

If the reader will now refer to *fig.* 845, he will see a perspective view of the fore part of the upper and under carriage, in which the names of the different timbers are written on them to render the subject clearer. *Fig.* 846 represents a view of the framing of the fore part of the carriage by itself. In *figs.* 845 and 846 the place of the perch bolt is marked by a small circle, *x*, in the middle of the upper side of the fore transom and of the fore axle bed, it being this pin that connects the under with the upper carriage, as above stated, and by which one turns on the other.

It remains now to explain the circles seen in *figs.* 841, 842, 843, 844, 845. To keep

Fig 845.

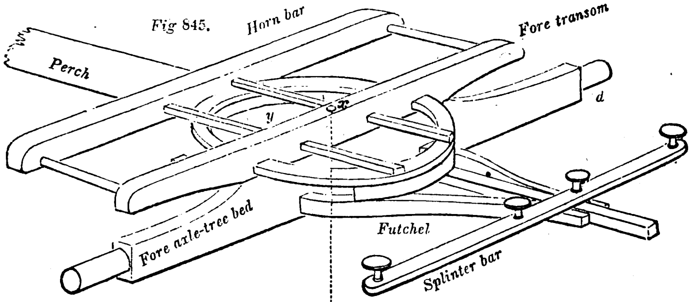

Fig. 846.

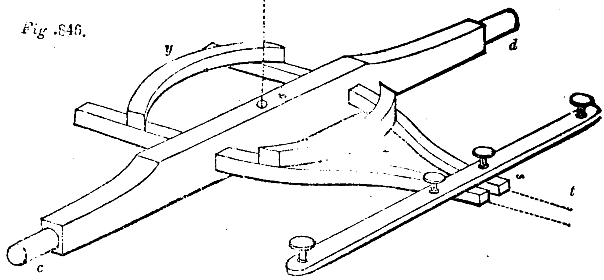

the upper and under carriages more steady, in turning them, than if there was only the perch bolt to depend upon, and to give a greater bearing to the upper one, a circle of iron, or, rather, an annular plate, called the *wheel plate*, is fixed on the under side of the fore transom, and, of course, between it and the fore axle bed; and, to bring its bearing to the futchels, short pieces of wood, being portions of circles, are placed under it at *y* and *z*, *fig.* 846, of which *y*, *fig.* 846, is called the *sway bar*, and *z* the *felloe piece*. The edge only of the wheel plate can be seen as a thick black line in *figs.* 845 and 846, because the upper side of the plate is protected by a circle of wood. It may be observed that this wheel plate, being attached only to the fore transom, which is a part of the upper carriage, remains always fixed, the under carriage turning against it. *c* and *d*, *figs.* 845 and 846, are the axle-tree arms on which the wheels revolve. Having thus explained so minutely the various pieces of the fore part of the upper and under carriages on *figs.* 845 and 846, it will be unnecessary to go over the ground again by a reference to the wheel plate in *figs.* 841, 842, 843, 844. In *fig.* 844 the springs are represented, *w* and *x*, from which the carriage is suspended, as in the complete representation of a coach, *fig.* 853. The construction we have just described may be seen in almost every private and hackney coach; and the reader who wishes to have a perfectly clear idea of the subject will do well to follow our description by an actual examination of one of these carriages; but it must be stated that, to render the wood-cuts simpler and more easy to be understood, we have purposely omitted all the ornaments with which the various timbers are usually decorated.

6494. *Springs of Carriages.*—Having now explained the construction of the carriage part of a coach, and other four-wheeled vehicles of the first class, the next subject that demands our attention is the manner in which the *body*, or place for the passengers, is connected with it. The most ancient wheel carriages were without springs or any other method of lessening the jarring produced by rapid motion over rough roads, which, in the antique cars, as represented in bas-reliefs, appeared to be so considerable, that the drivers were obliged to stand upright to enjoy the benefit derived from the elasticity of their muscles. The simplest, and probably the first method of affording ease, was to suspend the seat by straps or lashings. The next improvement would be the separation of the sitting part from the frame carrying the wheels and axles, and the supporting of the former by long ropes or straps stretched beneath it, and fixed to uprights rising from the frame: a construction borrowed, doubtless, from the horse-litter. The four-wheeled carriages of Europe, used for state purposes, were constructed upon this plan; and their great weight and slow movement prevented any violent concussion. Many of the stage-coaches of France are suspended on the same principle, as well as many of the carriages in Canada. In countries where the roads are very bad, the use of springs is scarcely admissible, as they are then very liable to be broken. In these cases, considerable weight is useful to prevent the vibration from side to side. Elastic substances, to prevent the concussion, are an improvement on suspension only. Wooden springs were first used, suggested, no doubt, by the elasticity of the bow; and some of these were in use not long since. Steel was next employed for a spring, and at first it consisted of one piece only, tapering; but afterward several laminæ of steel plates bound together, as at present, were found to be better, as being less liable to be broken.

6495. *The method of connecting the body with the carriage part forms one of the most important distinctions in carriages*, and much of the ease of the passengers depends upon the particular manner of effecting it. It is either now suspended by *strong leathern braces attached to springs rising from the carriage part*, in the manner of the coach, *fig.* 853, or, without any suspending traces, it is placed *upon the carriage part, springs of some kind intervening between this and the axles*, as in the phaeton, *fig.* 857.

In the carriages that have the bodies suspended by braces and springs there are sometimes, likewise, other springs beneath the carriage part, resting on the axles. In the latter case the vehicles are termed *under-spring carriages;* and these are the easiest of all for the passengers.

6496. *It is necessary that we give a technical description of the various kinds of springs now constantly employed to diminish the jarring or jolting occasioned by obstacles on roads.*

6497. *Single elbow springs, fig.* 847, are nearly straight, being only very slightly curved, and consisting of several plates of steel laid upon each other, and each shorter than the others, so that the whole tapers from one end to the other, the largest plate being the thickest. The several plates are kept together by hoops or clips.

Fig. 847.

6498. *The double elbow spring, fig.* 848, is the single elbow spring repeated right and left. Examples of it may be seen in the modern phaeton, Tilbury, Dennet, Stanhope, and in most two-wheeled carriages, where it is fixed across the axle at right angles. It is also used in the omnibus and stage-coach.

Fig. 848.

When the weight leans upon the spring by means of curved pieces of iron, called *loops, fig.* 849, which are connected with the springs by shackles, *b, b*, it is called the *grasshopper spring*, and is used in the Dennet and light carts. The longer the springs are, the more elastic and easy is the motion.

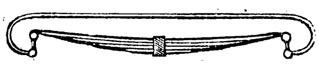

Fig. 849.

6499. *Double curved springs, called S springs*, were formerly the principal springs to which the bodies of four-wheeled carriages were hung by suspension braces; see *fig.* 853, in the coach; but they are now scarcely ever used, being superseded by the spring described next.

6500. *C springs, fig.* 850, are now universally employed for suspending the bodies of carriages with perches, as may be seen in the cuts of the coach, *fig.* 853, chariot, *fig*, 855, &c. One great advantage of this form over the S spring is, that the leathern brace is stretched round the back of it, and can be tightened by means of a small iron axle and notched wheel called a jack, *a:* this is rendered necessary occasionally, because the weight of the body gradually stretches the braces, causing the body to sink down nearer to the ground. Accidents from breaking rarely occur in C springs, though they are frequent in double elbow and elliptic springs. The C springs, also, from their long braces, yield a universal motion before, behind, downward, and sideways, and therefore are the easiest for the rider, though not for the horse; whereas elbow and elliptic springs are confined to vertical action, which is less easy.

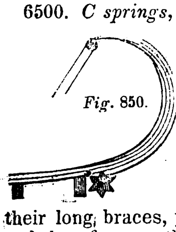

Fig. 850.

6501. *Elliptic springs, fig.* 851, are those most commonly now used in modern light carriages without perches. They consist of two curved springs placed on each other with the concave surfaces opposite, and connected together at the ends, forming nearly the figure of an ellipsis. They are placed on the axle-trees at right angles, and the weight of the body bears upon the upper spring. Examples of these may be seen in all the four-wheeled carriages without perches. They are less easy than the C springs with braces; but, through the great improvement of roads and pavements, they are not much inferior in this respect. They are easier than the double elbow.

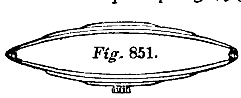

Fig. 851.

6502. *When under springs are used* in under-spring carriages, mentioned above, the most usual one is a curved spring like the lower part of the elliptical; but, instead of another curved spring being placed above this, there is a curved iron, *fig.* 852, simply called a *dumb stay*, because in this case so much elasticity is not required.

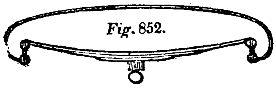

Fig. 852.

6503. *Combinations of several of the above springs* are employed in various carriages, and receive different appellations by coach-makers. Thus, when four elliptic springs are used in a four-wheeled carriage, the whole is termed the *nut-cracker springs*. *Telegraph springs* are a combination of eight springs, when used in four-wheeled carriages. Two of these are placed longitudinally on the frame-work of the body, and two transverse ones are suspended from it by shackles; on the latter the weight rests, and thus the body is placed two removes from the concussion. The Stanhope is suspended on four of these springs: from the small space they occupy, they are constantly used in stage-coaches; but they are not very easy without a great weight on them.

6504. The springs of carriages are made of a peculiar kind of coarse steel prepared expressly, and having little carbon, that they may be less brittle. Forging coach-springs is a peculiar branch of business. Though springs are kept painted, yet they are liable to decay by the rain, forcing its way between the plates, rusting the inner surfaces. Mr. Adams recommends tinning each plate before putting them together. Mr. Adams likewise observes that a difficulty arises in adjusting the elasticity of springs to the weight of the carriage; for if springs are calculated for a certain weight, say six persons, and only three enter the carriage, the springs will be found too hard, and with more weight the carriage would be easier. Even when properly adjusted, light carriages are not so easy to ride in as heavy ones, because the concussion on a rough road takes more effect on a light carriage, in causing it to rebound, than it does on a heavy one.

CHAPTER III.

DESCRIPTION OF THE FOUR-WHEELED CARRIAGES WITH PERCHES.

The following representations of carriages are all drawn accurately to the same scale, which is placed below the wood-cut of the coach.

6505. *The coach, fig.* 853, is the principal carriage in use. It is properly a four-wheeled carriage, with two seats within, and capable of holding four or six persons. There are several varieties, but the *town coach* is the most complete. Of this the carriage has been already described. The *body* is now always suspended by braces and C springs, the braces passing over the springs so as to be tightened by winding round a *jack* placed at the bottom. This is a great improvement on the S springs, *fig.* 854, used not many years back, and which could not, from their form, be so tightened. The body is attached to the braces by curved irons, called *body loops*. Some coaches have the coachman's seat covered by a rich hammer-cloth, supported upon the horn of the loop by means of branch iron-work, and others have a *Salisbury boot*, like that of the chariot, *fig.* 855. The *platform* behind for the footmen is best suspended from the body, or from the C springs, which, in that case, ought to be very strong; when placed merely upon the carriage, the jarring is intolerable. Some coaches, besides the C springs, have also under springs, as in the chariot, *fig.* 855, and these are

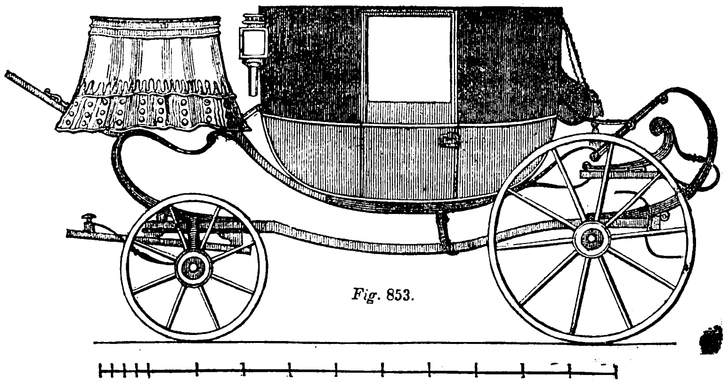

Fig. 853.

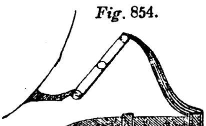

Fig. 854.

by much the easiest. When there are under springs, the footman's platform is generally placed upon them, though the jarring is still very considerable. Coaches have the great advantage of affording the most comfortable accommodation to a family in all weathers ; but having no convenient lookout in front, they are not so agreeable on some other occasions as other vehicles which have been substituted for them; they are, however, upon the whole, the most complete of all carriages.

6506. *Crane-necked carriages* are so called from a particular form of perch, which obviates the difficulty which we have dwelt upon respecting the limit in turning the fore wheels. The crane neck is formed by removing the perch of wood, and substituting two long bars of iron arched upward in front, as in the phaeton, *fig.* 857, somewhat in form of the neck of a crane, by which means the fore wheels can pass underneath in turning. This answers the desired end, and adds much to the strength of the vehicle, but likewise much to its weight. This contrivance is not modern; and as coaches were formerly kept only by the rich, who could afford to keep abundance of horses, the difficulty of draught was not regarded as of much consequence ; at present it is almost entirely confined to state equipages, all of which are so built, on account of its elegance and convenience in turning; but the description of these does not come within our limits.

6507. *Travelling coaches* are now seldom used, lighter vehicles being found more convenient. When an ordinary coach is used for travelling, it is fitted up in a particular manner. The hammer-cloth is taken off, and, instead of the Salisbury boot, another, of a square form, is introduced, capable of holding trunks. It may be interesting to notice that formerly, instead of the present boot made of boards covered with leather, one made simply of stiff leather was made to hold the luggage, called a *budget*, whence the term so well known to politicians. A similar one is placed behind, or a seat for servants, supported on the springs. Two flat boxes covered with leather, called *imperials*, are sometimes placed upon the roof of the body, and even a contrivance beneath the body, called a *well*. *Venetian blinds* are added to the windows; a *chain* and *drag-staff* are added for going down hill, and a *tool-budget* should never be omitted.

6508. *The landau* is a coach having the upper part to throw open occasionally in fine weather. This is effected by means of jointed metal levers, called *irons*, on the upper quarters, as in the pilentum landau, *fig.* 870. When the carriage is required to be open, the two quarters separate in a joint in the top, and each folds back. These carriages, which are hung and fitted up in every respect like a coach, are extremely convenient, as they answer the purpose of an open and close carriage, without the expense of keeping two, and accommodate many persons without the care of driving, as in other open carriages. The bodies not being assisted by the connecting strength of the upper framing, it becomes necessary to make the lower parts of stronger materials, and even to have much iron-work, which somewhat increases the weight; also, the upper quarters, with the joints, are obliged to be covered with the leather, which, though well blacked, has not the same good appearance as that of coaches with fixed roofs, and, after much use, looks indifferently. It appears, nevertheless, to be a kind of carriage, upon the whole, well suited to our uncertain climate, and if built light, without a perch, and with elliptic springs only, is found extremely useful. They are sometimes made narrow, to be drawn by one horse.

6509. *The landaulet* is a chariot having the head to open, in the same manner as the landau: there is, of course, only one seat. The same observations may apply to it as to the latter carriage.

6510. *The barouche* is constructed like the lower part of a coach, with a perch, and two seats in the body, and hung on C springs; but it is essentially an open carriage, having no roof, and only sometimes a jointed head, to put occasionally on the hinder part. The driver's seat is in front, and there is seldom a place behind for the footman, who sits on the box with the driver. It was formerly a very fashionable carriage, and is extremely agreeable in fine weather, and convenient for a party, but it is not calculated for bad weather. The head may be closed in by a glass frame, like the britzschka, but this is inconvenient; and this carriage is now much superseded by the britzschka, which answers several purposes.

The barouche, together with the phaeton, britzschka, and some others, come under the denomination of *open carriages*, as the coach and chariot are *close carriages*.

6511. *The barouchet* is to a barouche what a landaulet is to a landau, an open carriage with a head, and in form like the lower part of a chariot.

6512. *The sociable* was a carriage formerly in use, constructed like the barouche, but with sides of worked cane.

6513. *The chariot* differs from the coach in having only one seat, and it is, in fact, like a coach with the fore part cut off, whence the French appellation, a *coupé*. It is hung in the same manner as the coach, with C springs, and has, as well as the coach, what the coach-makers call a compass perch; sometimes, also, it has under springs, as *fig.* 855. The Salisbury boot, as in the wood-cut, and hammer-cloth, are the same as in the coach. It is considered as the most elegant for a dress or court carriage, but is

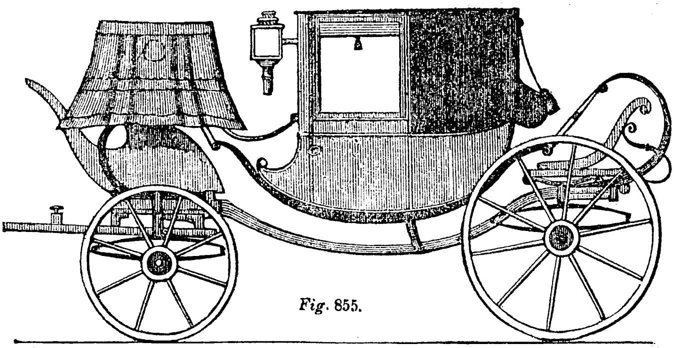

Fig. 855.

not any lighter than a coach, though more agreeable to the eye, and affording a view in front. The very best work of every kind is executed in this carriage, and good taste is exercised in the painting, varnishing, and other decorations in a chaste and not gaudy style.

6514. *Travelling or posting Chariot, fig.* 856.—When the chariot is intended for trav-

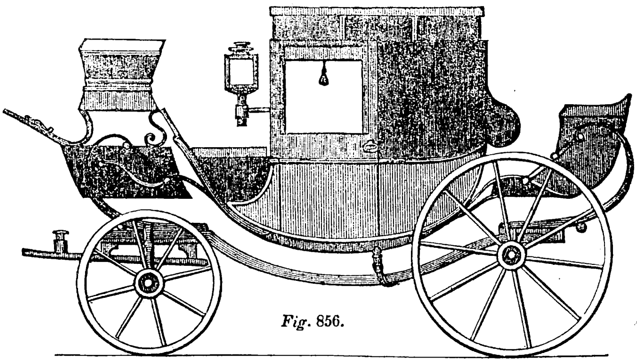

Fig. 856.

elling it is built somewhat stronger, the hammer-cloth is removed, and a driving-seat placed there. Families who travel with post-horses sometimes have their own carriages, which, among other conveniences, prevents the luggage from being shifted. The ordinary chariot is sometimes converted into the travelling one, by removing the coach-box, and supplying its place by a trunk-boot, the coachman riding one of the horses as postillion. A compass perch is used; and some have a crane neck, which admits of the fore wheel turning in less room in narrow streets; or sometimes a *swan* neck, which consists of a single perch instead of a double one, the arched part only being of iron. Another trunk-boot is placed behind, with a seat for servants: on the roof is placed a large square box, called an *imperial*, and sometimes there is also a case below the body, called a *well*. All these are covered with water-proof black leather, and they are well secured by leather straps and buckles. There are likewise Venetian blinds to the windows, and a sword-case, drag, and chain. So many conveniences are useful, because it is not uncommon, in some countries, to be obliged to carry portable tables and stools, beds and beddings, together with some cooking and other utensils. For persons who wish to lie at full length, the front panel can be taken out, and a boot added at the bottom of the body to stretch the legs and feet into; this is termed a *dormeuse*. A chain, shoe, and staff are likewise necessary on a journey. The chain is to lock one of the wheels, to check the velocity in going down a hill. The shoe is to put under the wheel, and the staff is to stop the carriage, to give a rest to the horses on ascending a hill. The chain is fixed to the middle of the perch, and is covered with leather, to prevent it from rattling. A box with some necessary tools should never be omitted in case of an accident, such as a wrench, hammer, chisel, saw, pincers, a few bolts, nuts, and screws, &c.

6515. *A light travelling chariot* may be put upon elliptic springs without a perch; but particular care should be taken that the body is well secured by iron plates, as in that case these alone will connect the fore with the hind carriage. This will not be so easy a vehicle as when hung with C springs, X braces, and will require very smooth roads.

6516. *The post-chaise* is of the same general form as the travelling chariot, but, being intended for quick travelling, is built light; and, to render it still lighter, there is no coach-box, the driver sitting on one of the horses.

6517. *The phaeton of the end of last century* was a very lofty, open, four-wheeled carriage, with a jointed head, *fig.* 857; it had a very showy appearance, but, from its preposterous height, was far from being safe, whence probably its appellation from the fabled car of the son of Apollo. It was for some time much in fashion, and was a favourite driving carriage of George IV. when Prince of Wales, and also of Sir John Lad, and other whips of the time. There were several varieties, of greater or less elevation, and, consequently, hazard to the driver; but we give, in *fig.* 858, a representation of the crane-necked phaeton, with iron perches, from Fulton's work "On Carriages," with a view to show the absurdity of the taste of those days, and the improvement that has taken place since in carriage building. It was considered, from its comparative lightness and elevation above the dust of the roads, to be an improvement on former vehicles, and safer than those with two wheels; but this lofty construction has now gone entirely out of use, in consequence of the numerous accidents, often fatal, which occurred.

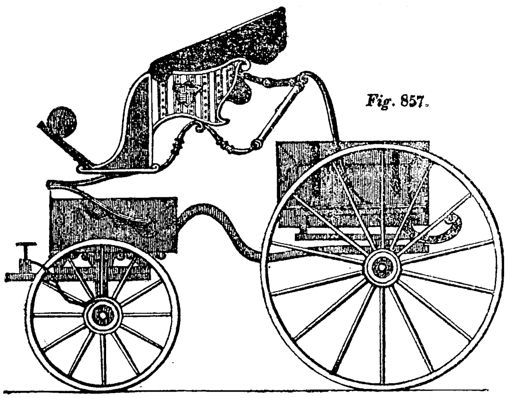

Fig. 857.

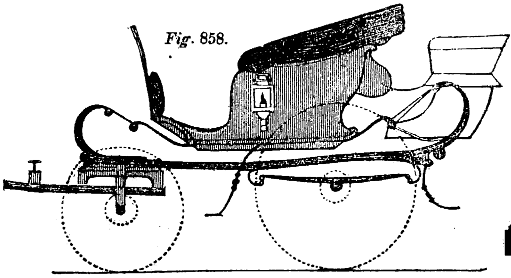

Fig. 858.

Fig. 858 represents a *perch phaeton*, not long since made; somewhat after the old fashion, but much reduced in height.

6518. *The modern phaeton, fig.* 859, bears scarcely any resemblance to the fashionable vehicle of former times, but is one of the simplest forms of four-wheeled carriages in ordinary use. "It is," says Adams, "literally a long box and locker for luggage, usually painted black, with an arm-chair and hood in front, and a bench behind; an arch in the locker is usually contrived to permit the fore wheel to pass beneath, and thus allow it to be much higher." The body rests on four cross springs, whose ends are suspended from four side springs placed across the axles. These springs are connected at the ends by links called *shackles*, as in the ordinary stagecoaches, which, if not properly constructed, are apt to occasion a jingling noise. Some have substituted leathern braces instead of them. By those who like to drive themselves, the body with the driving-head is placed in front, as in the wood-cut; and the phaeton is generally double bodied, that is, having another seat behind: but the seats may shift their places, in order that a servant may drive in bad weather. Though convenient for town use, or for travelling, being light, with rather large wheels, yet it is not very graceful, and is now much superseded by the britzschka.

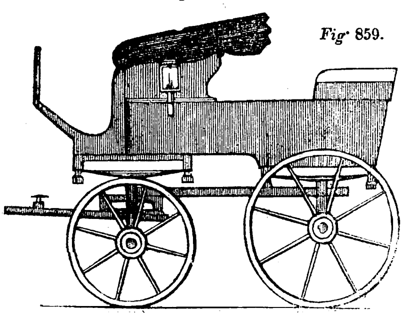

Fig. 859.

6519. *The under-spring phaeton* is suspended on C springs, and has likewise double elbow mail, or elliptic springs.

6520. *The shooting phaeton* is fitted up with a receptacle in the body to carry dogs, game, &c.

6521. *The britzschka* is a carriage lately introduced from Germany, and, on account of its great convenience, has become extremely common. *Figure* 860 represents the original German britzschka. The body is so long that the traveller may recline at full length and sleep, a convenience not possessed by other carriages. It has a perch with C springs: the head is sometimes fixed as in the wood-cut, but is sometimes, also, moveable: for cold weather it is closed in front by an ingeniously-contrived shutter, with panes of glass, which folds up in a recess, and which, when let down, fills the whole front, closing with a tight joint. The wheels are rather low, and the driver sometimes sits in the body of the carriage, or he may have a seat in front. The part of the body not sheltered by the head is covered by a moveable wooden flap, which folds back in several pieces.

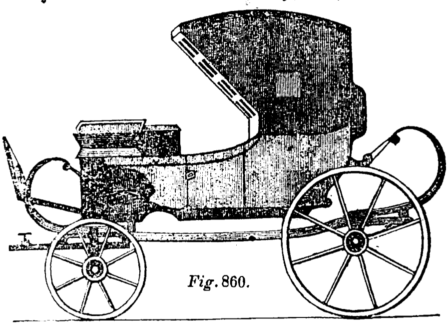

Fig. 860.

6522. *The britzschkas made in England* have nearly the same form, *fig.* 861, but are

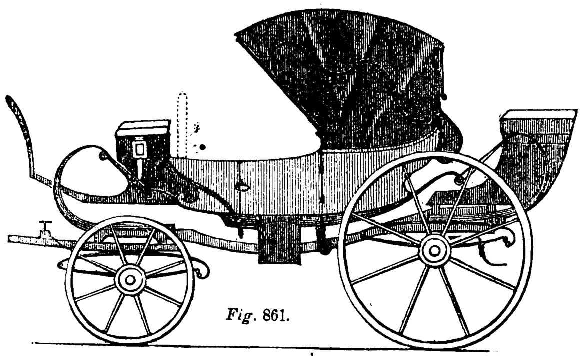

Fig. 861.

more convenient. The head is always a moveable calash, and there is a place for the driver in front, and a seat for servants behind. Though in wet weather, when the head and glass frame are up, and the knee-flap down, the body will hold but two persons, yet in fine weather two more can be accommodated, by raising the knee-flap, which folds back, so that part of it, padded on the lower side, stands upright, as in the dotted line *a*, and serves for a back to those who are on an additional seat: some of these britzschkas are also made with additional under springs, or put upon elliptic springs. For travelling, sometimes the driver's seat in front is removed, to give room for more trunks, the driver sitting on one of the horses.

6523. *The vis-a-vis* was a carriage formerly fashionable, though now not in use. It was, as the French name implies, a narrow coach, in which only two persons could sit face to face. The advantage of it was that, on account of its small size, the passengers could not be jolted against each other, and, being confined, it was warmer than larger carriages.

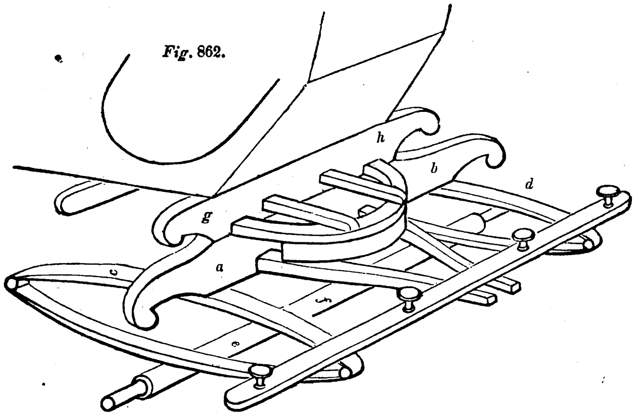
6524. *The sulky* was a name given to a carriage used formerly, built light, with one seat, in the form of a chariot, but, like the vis-a-vis, with the seat so contracted that one person only could sit on it; and it was so called from the proprietor's desire of riding alone.

CHAPTER IV.

FOUR-WHEELED CARRIAGES WITHOUT PERCHES.

6525. Within these few years a numerous class of carriages has appeared without perches, having the driver's seat attached to the body, which rests upon the axles, with elliptic springs intervening, see *fig.* 862: they are usually termed "elliptic spring carriages" One material advantage attending the omission of the perch is, that the

Fig. 862.



body can be brought near to the ground, thus lowering the centre of gravity of the vehicle, and rendering it safer and less liable to be overset; it also affords greater convenience of ingress and egress. These carriages are particularly suited to the infirm, and ladies who find it difficult to mount the high steps of an ordinary coach. They are also less expensive to build, and, being lighter than perch carriages, do not require such strong horses; but they are not quite so easy for the rider as perch carriages with suspension braces and C springs, although the improvement of the roads by Macadamizing has rendered them little inferior when the springs are well made.

By comparing the construction of the fore part of the carriage of one of these, in *fig.* 862, with that of perch carriages, in *fig.* 845, the difference will be readily perceived. In the elliptic spring carriage, the fore transom, *a b*, instead of resting upon a fore axletree bed, as in *fig.* 845, bears upon the elliptic springs *c* and *d*; and these rest upon the iron axle *e f*, without any bed of wood. The bar *g h* is fixed to the bottom of the body of the carriage, and a bolt similar to the perch bolt passes through this bar and the fore transom, *a b*, on which the carriage turns, the wheel plate and futchels being the same as in the perch carriage; *g h*, therefore, belongs to the upper, and *a b* to the under carriage, the principle of turning being the same in the carriages without perches as in those which have them. These four-wheeled carriages on elliptic springs, and without perches, are now so numerous, that it is impossible to go into the streets of any of our principal cities or towns without seeing some of them; and they are best examined in the objects themselves after the clew which has just been given.

6526. It has been stated that when the wheel of a carriage comes in contact with any impediment, it is most essential that the whole of the impetus or momentum which the carriage has already obtained in moving should be brought into full action; and, consequently, that no elasticity should intervene between the wheel and the load in the direction of the progressive motion, that is, longitudinally. But carriages hung upon C springs admit of a very considerable longitudinal movement in the body of the carriage, and, on that account, they are the most heavy to draw. Cabriolets hung in this manner require heavy, powerful horses to drag them, whereas vehicles with grasshopper and elliptic springs have no elastic motion in a longitudinal direction, but only an up-and-down motion; they are, therefore, much easier to pull, and may be drawn by lighter horses. Carriages suspended on C springs are the easiest for the passenger, though not for the horses; because with them there is not only a longitudinal, but likewise a side motion, as well as a perpendicular one, which causes the jolting from passing over stones or other obstacles to be less felt than with grasshopper or elliptic springs. Now, however, from the great improvement in our roads, carriages on elliptic springs are nearly as easy to the rider as those on C springs, and, being much lighter for the horses, are much in fashion. The more elasticity, or, in other words, the more action there is in the latter springs, the more effect will they produce in diminishing the draught: with a C spring a contrary effect is produced. The greater the elasticity, also, the more will springs lessen the sudden shocks to the load. Some are of opinion that post-chaises, which are now hung on C springs, may afford all the ease that is required by placing them on well-constructed grasshopper springs, and with considerable advantage to the horses.

Much of the forms and construction of carriages depend upon the roads, since it is requisite to suit them to the condition of the latter. The late improvements on roads have had a considerable effect upon modern carriages, which are now built much lighter than formerly, when greater strength was required to resist the concussions caused by obstacles.

6527. *Phaetons are now very generally made without a perch*, and placed upon elliptic springs. *Figure* 863 is one of this kind, in which the body is nearly the same as in the phaeton with a perch.

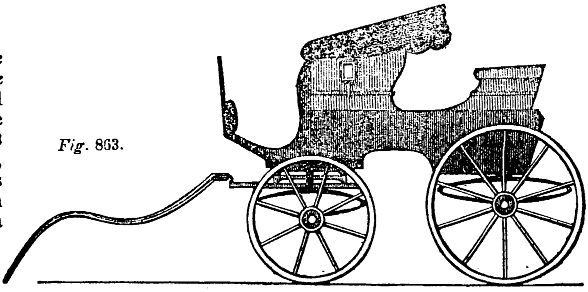


Fig. 863.

Fig. 864 is a variety called a *Stanhope phaeton*.

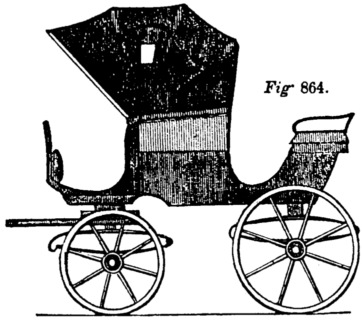

Fig. 864.

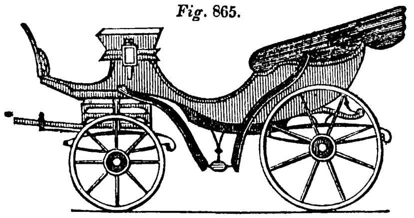

Fig. 865.

6528. *A pony phaeton* is a small, light phaeton with low wheels, intended for parks, where ladies can drive themselves ; but a boy may ride as postillion on one of the ponies

6529. The cab phaetons, *figs*. 865, 866, are other examples of the varieties of this kind of carriage that have appeared of late. These are sometimes hung on C springs with a perch ; and sometimes the upper part of the body is of cane.

6530. *Fig*. 867 is a cab phaeton with a hard seat.

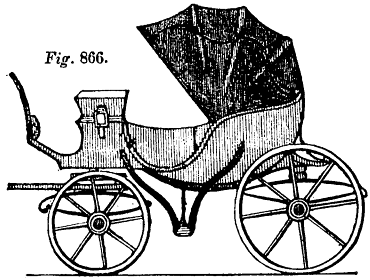

Fig. 866.

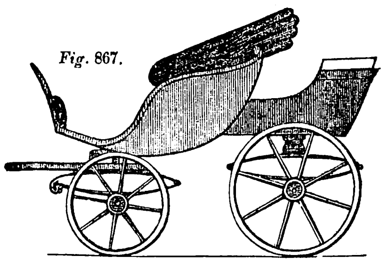

Fig. 867.

6531. *The pilentum, fig*. 868, invented by Mr. Davies, coach-builder, of Wigmore-street, London, is one of the most characteristic of carriages without a perch. It is a four-wheeled carriage, the fore and hind parts of the body resting upon the elliptic springs that are placed upon the iron axles. The central part of the body, with the door, is brought down very low, affording easy access; and the box and driving seat, instead of being detached from the body, form one mass with it. Leather splashers are placed on each side of the

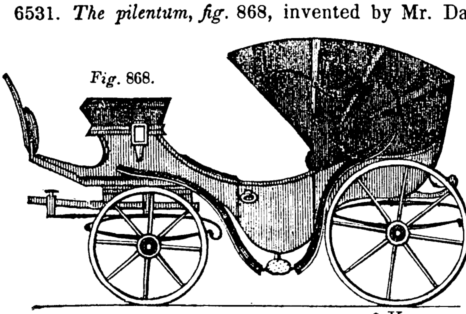

Fig. 868.

door to defend the passengers from the dirt of the wheels. This carriage has usually a head to throw up, and may be open, or furnished with a glass and frame in the manner of the britzschka.

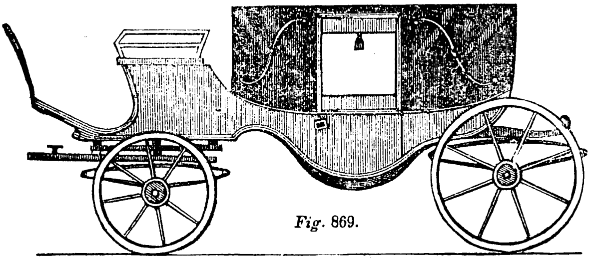

Fig. 869.

6532. *The pilentum landau, figure* 869, is another carriage by Mr. Davies, on the same principle, on elliptic springs, and the centre of the body brought low.

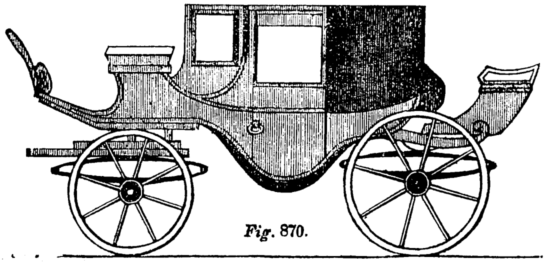

Fig. 870.

6533. *Fig.* 870 is the construction called a *Clarence.*

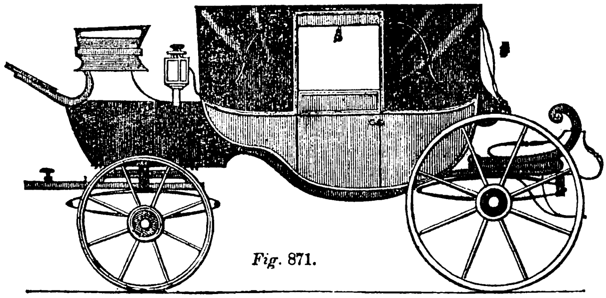

Fig. 871.

6534. *Fig.* 871 is a landau on elliptic springs.

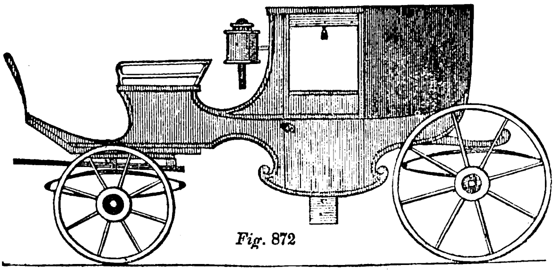

Fig. 872

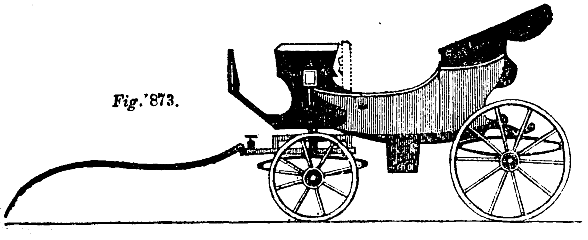
6535. *The sovereign chariot, fig.* 872, by Mr. Davies, exhibits another instance of the adaptation of the principles we have mentioned.

Fig. 873.



6536. *The demi-britzschka, fig.* 873, is a small four-wheeled carriage in the form of the britzschka, but without a perch, and placed on elliptic springs. By lifting up the knee-flap, it will accommodate four persons in fine weather. It has a German shutter for bad weather, when it can only accommodate two persons.

6537. *The Pelham, fig.* 874, is another of Mr. Davies's carriages, having some of the qualities of the britzschka.

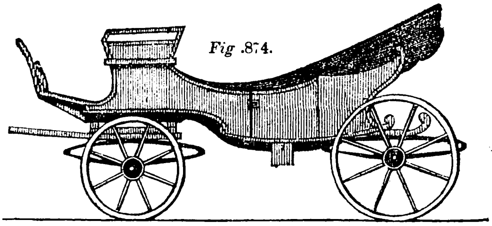


Fig. 874.

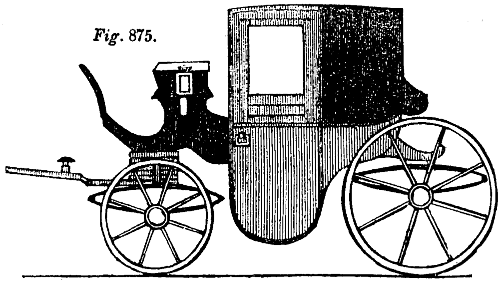
6538. *Fig.* 875 is a small light carriage, having the body brought very near the ground, extremely convenient for invalids. Its form is borrowed from one of the street cabs, but it is larger and more elegant.

Fig. 875.



6539. *Of hackney cabs, fig.* 876 is an example of the usual construction, which is found very compact and convenient.

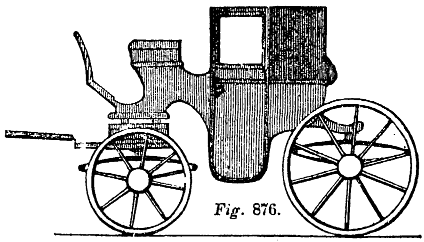


Fig. 876.

Fig. 877 is another example, in the form of a small chariot.

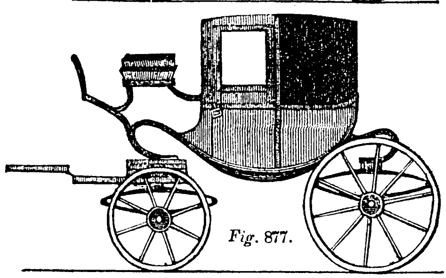

Fig. 877.

6540. *The droitzschka*, or, as it is commonly called, *drosky*, is a Russian carriage, *fig.* 878, being the most common vehicle for hire in the streets of Petersburgh and Moscow. It is described by Mr. Barrow as a very low four-wheeled carriage, the body of which is near the ground; it is, in fact, a narrow bench on wheels, at the hinder part of which is a small back, about as high as the middle of a man's body, and against which he leans, sitting straddling across the bench, with his legs straight down on each side, as he would sit on horseback. If a second person be in the drosky, he sits on the same bench sideways, with nothing to rest his back against. In front of all is the driver, with his legs also across it, and separated from the person next to him by a small iron bar about six inches in height. The form of the droskies kept by private gentlemen is the same, but they are more ornamental: they have padded seats and backs, and splashing-leathers to keep off the dirt from the wheels. Mr.

Fig. 878.

Barrow found these vehicles both unpleasant and dangerous, from the jolting and the difficulty of the rider keeping himself on the bench, which serves as a seat. A carriage bearing the same name is now built in this country; but Mr. Adams observes that, "instead of its being similar to the Russian, it is rather a modification of the elliptic spring britzschka, by placing the passenger's seat nearly at the level of the hind axle, and sinking the central part of the body below the level of the axle for the legs." The Russian vehicle, however, appears to have suggested the great improvement of bringing the body of some of our new vehicles so low; and this may be seen well exemplified in our common four-wheeled hackney cabs.

6541. *The equirotal carriage* is an invention of Mr. Adams, an eminent coach-builder. Considering the defects occasioned by having the fore and hind wheels of different sizes, he makes all his wheels of the same size; hence the name given to his carriages. By this construction, he equalizes the friction of the wheels; and to enable them to turn readily, without adopting the usual methods, he separates the fore wheels, with the driving seat, from the body of the carriage with the hind wheels, by vertical hinges, which causes the driver to turn with the fore part of the carriage, thus having more command of the horses; whereas, in the usual construction, in which the driver remains in the same position while his horses are turning, he is sometimes almost dragged off. These principles, which are solid and just, are applied by the inventor to all sorts of four-wheeled vehicles, from the coach to the wagon.

CHAPTER V.

TWO-WHEELED CARRIAGES.

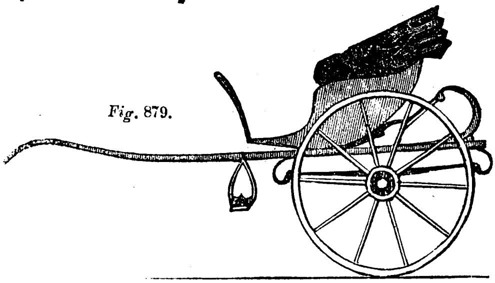
6542. The simplest two-wheeled vehicle is the common cart; this, made lighter and more elegant, and put on some kind of springs, constitutes the spring-cart, the buggy, and chair. With the body suspended, and put upon good springs, it has been improved into the one-horse chaise. The gig, the cabriolet, the Dennet, the Tilbury, and Stanhope are all varieties or improvements upon this. For lightness and simplicity, two-wheeled carriages are preferable; their comparative less cost, their being drawn by one horse, and consequently their economy, are the principal reasons for their being used. But they are not so agreeable to ride in as phaetons, owing to their unpleasant motion; neither are they so safe as four-wheeled carriages, because if the shafts give way the body falls to the ground with the passengers, who are precipitated forward with great violence: they are also more difficult to turn than those carriages that have two axles, one of them moveable. Those which are entirely open, without any kind of head, though light and well calculated for rapid travelling with a single horse, are inconvenient in rainy and cold weather; and the head, when it is up, is apt to be much affected by strong wind, and is not a complete security from the rain. Nevertheless, with all these and other drawbacks, they possess advantages sufficient to be very generally in use. Of two-wheeled carriages, some are suspended by braces and C springs, and others have the bodies placed upon springs beneath the shafts; occasionally, also, under springs can be used.

6543. *The shafts* are the long side framings of two-wheeled carriages which extend on each side of the horse, and answer the same purpose as a pole in a four-wheeled carriage, to draw and turn the vehicle by. As a considerable portion of the weight rests upon the shafts, it is essential that they are sufficiently strong, since in breaking the body must fall forward and throw out the sitters; but it is likewise proper that they shall have elasticity as well as the toughness requisite to render very great thickness not necessary. Ash is found, upon the whole, to be the best material for shafts, and they are strengthened by iron plates on the under side. Lance wood, obtained from the West Indies, has been much employed for shafts, on account of its great elasticity, which enables it to be much lighter than those of ash; but though valuable on account of its elasticity, it is a brittle wood; and being less to be depended upon than ash, it is much less used. It is strengthened by whalebone on the bottom, its elasticity preventing the use of iron.

6544. *Celerity of motion being one of the most desirable qualities in two-wheeled carriages*, the great art is to build as light as possible, yet so as to be sufficiently strong. Ash is the timber usually employed; the form depends much upon fashion. Very light carriages are never so easy to ride in as heavy ones, even when the springs are proportionally adjusted, for the concussion of a rough road takes more effect on a light carriage than it does on a heavy one. Gigs, and other two-wheeled carriages to be used in the country, should have their axles sufficiently long for the wheels to fall into the cart-ruts, and additional strength is required.

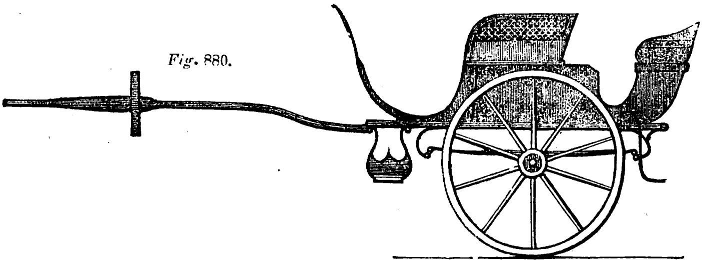
6545. *Cabriolet, fig.* 879.—"This," Mr. Adams observes, "is, in reality, a regeneration of the old one-horse chaise in a more elegant form, which has been borrowed, together with its name, from the French; and, as is common in most such cases, it has been improved upon. The form of its body, which is its characteristic feature, resembles that of the nautilus shell, and it has a head to raise up in bad weather, with curtains to draw in front, or it may be closed in by a German shutter. The knee-flap, instead of being a piece of flexible leather, as in the apron of the old one-horse chaise, is stretched tightly across a frame, which answers better." Though an elegant vehicle, it is not very safe when moving at a rapid rate. The body is hung on C springs, and braces behind, and it has a double elbow, or grasshopper spring beneath, resting on the axle; besides these, there are two small brackets affixed beneath the shafts, to take two straight springs which are bolted to the body. It is a convenient carriage for a single man to ride about town in, as it affords shelter from the weather, and, as the owner can drive it, it saves the inconvenience and expense attending on a close carriage with servants. A boy, however, may be carried behind, cut off from communication with the riders, and who may take charge of the vehicle. Its weight requires powerful horses, and to run a cabriolet about town all day two are required; and if day after day, three will be necessary.

Fig. 879.



6546. *The curricle, fig.* 880, differs from other two-wheeled carriages chiefly in being

Fig. 880.



drawn by two horses abreast instead of one; and it is the only two-wheeled carriage where two horses are employed. It has no shafts, and the body is suspended in a similar manner to the cabriolet. A pole is inserted into the front cross-bar of the carriage frame, and passes between the horses; from this a metal bar is suspended, resting on the horses' backs (represented in the wood-cut as turned upright); this, and the pole sustaining the weight of the carriage and passengers, is the same manner of yoking as that of the classic car. It fatigues the horses less than a four-wheeled carriage, but, as the safety of the vehicle depends entirely upon the strength of the pole, there is great risk in case of the horses becoming restiff. It is seldom made of a graceful form, though it might be so by a person of taste; but it has been almost wholly disused of late, perhaps on account of its want of safety. Any one-horse vehicle may be easily converted into a curricle by substituting a pole for shafts; but the curricle is usually made expressly with some peculiarities. *Fig.* 880 is a curricle, in form resembling a Stanhope, with a seat behind.

6547. *A tandem* is not, as some suppose, a particular kind of carriage; but the term (probably from the Latin *tandem*, at length) is applied only to the manner of placing two horses to draw any two-wheeled carriage in a team, or one before the other. When the roads are very bad and heavy, it is sometimes necessary to add one horse in this way to relieve the other, and promote speed. This method, however, can only be used by those who are expert in driving, unless the fore horse is rode by a postillion. As this may be often useful, it is convenient for every one-horse carriage to have a loop at the point of each shaft for the leading horse to be fixed to.

6548. *A gig* is a one-horse chaise without a head, or an open railed chair, made of a light construction for quick travelling, sometimes suspended by braces and springs behind, and having in addition some other springs between the body and axle; and some gigs have only the latter springs. Gigs are made of a great variety of forms well known, and with various accommodations for luggage. The name gig includes the Dennet, Tilbury, and Stanhope, which are gigs of particular constructions and modes of hanging. They have always a space beneath for holding a portmanteau or other luggage.

6549. *The Dennet, fig.* 881, is a light two-wheeled carriage, said to be so named from

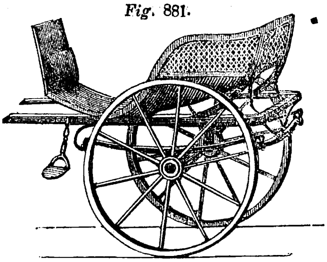


Fig. 881.

the Misses Dennet, two celebrated dancers. It is a gig made of various forms, but hung by a combination of three springs, two of them being placed across the axle at right angles, and the third suspended from them behind with shackles. The body may be with or without a jointed hood, and either of cane or close. The Dennet springs are very commonly used in light carts.

6550. *The Tilbury, fig.* 882, derives its appellation from a coach-builder of that name. It was for many years very fashionable, but it is neither sightly nor convenient, and though apparently light, it is in reality very heavy, from the quantity of iron-work: it is now little used. To support the body, it has an iron gibbet, *a*, fixed

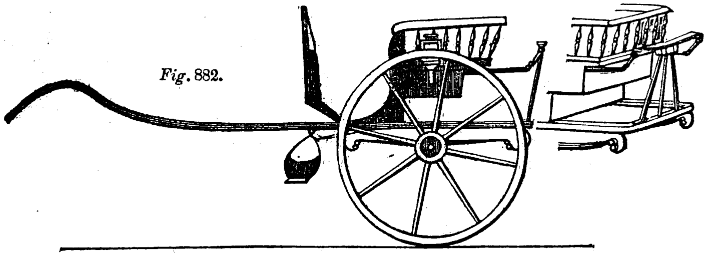

Fig. 882.

on the hinder part of the carriage, to which the body is suspended by leathern braces; and it has grasshopper springs fixed to the body beneath the shafts; likewise, in front there are two single elbow springs attached to the body, serving to suspend it by a short leathern brace. It has a small hose below the seat for luggage, and a cloth board in front.

6551. *The Stanhope, fig.* 883, resembles the Tilbury in the body, but has more room below for luggage. The origin of this carriage has been communicated to us by an eminent coach-maker well acquainted with the circumstances; Mr. Tilbury, who contrived the carriage that bears his name, was requested by Lord Stanhope to construct for him some novel kind of light carriage that should be called after him. Tilbury accordingly adapted to his own new carriage the springs that had just before been applied by Elliot to the mail, making some alterations. The springs of the Stanhope are accordingly the mail springs of that day. These consist of two springs fixed longitudinally on the side frame-work, and two transverse ones suspended from it by shackles; on the latter the weight rests. By this means the body is placed two removes from the concussion, but the shafts, and, of course, the horse, are exposed to the whole of it. This combination of springs is not easy without a great weight on them. Sometimes the upper part of the Stanhope is formed of cane-work, which gives it a lighter appearance, and now more frequently the body of the Stanhope is hung on the springs of the Tilbury.

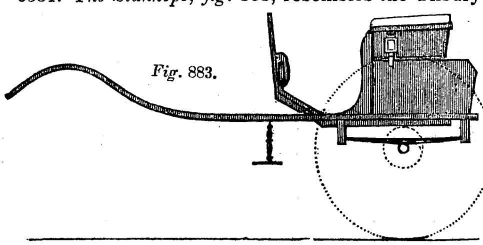

Fig. 883.

6552. *A whiskey, or chair*, is a small chair, not hung by braces, but placed on the shafts, having springs of some kind interposed between them and the axles. The most usual springs for this purpose are the double elbow. The body may be made with panels, or worked with cane. It is made very low and very light. In other respects it resembles the gig, and is the cheapest kind of spring carriage.

A kind of very low chair is sometimes made on two or four wheels, with or without springs, for a park; useful for invalids.

6553. *Buggy* is a name which has sometimes been given to a smaller one-horse chaise; sometimes it is so small as to contain only one person.

6554. *The jaunting car, fig.* 884, is a common travelling vehicle in Ireland, and is cheap, safe, and convenient, though not elegant. They are much employed as stage conveyances, and are likewise kept of a handsomer construction by private individuals. *Fig.* 884 represents one of the latter in a plain style, and calculated for six persons, drawn by one horse; the wheels are low, and the feet of the passengers come within a

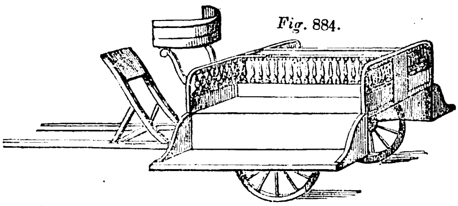

Fig. 884.

foot of the ground. Between both the seats is a space called the well, for luggage. Besides this, there are several other constructions. In some the wheels are outside, and the passengers sit face to face, instead of back to back, as in this figure; and these have sometimes the addition of upright standards and canopies for defence in case of rain, forming an economical summer carriage, extremely agreeable. The best kind are put upon springs. In the common country car, which is smaller, there is no separate driving seat, but the driver sits on the same seat with the passengers, or often runs before. Another modification, called "Bianconi's jaunting car," is on a larger scale, carrying four or five passengers on each side, has four wheels, and is drawn by two horses.

CHAPTER VI.

VARIOUS DETAILS RESPECTING THE PARTS OF A CARRIAGE.

6555. *The body* of a carriage is composed of a frame-work of ash, filled in with panels of soft, straight-grained mahogany, usually Honduras. The roof in close carriages is made of deal well blocked underneath, and covered externally with hides stretched and dried on, being afterward blacked. In some carriages the coach box and boot are connected with the body; in others they are detached and supported by the carriage part. At the back of the body there is a projection called the *sword case;* but in light carriages this is often omitted. In open carriages a *jointed hood or head,* covered with leather, is sometimes attached, and this is either permanently fixed, or made to take away if required. The most complete method of excluding the rain was described in the "Britzschka."

To give the body greater depth inside, without injuring the symmetry of the exterior, two pieces of wood, called *rockers* (because shaped like the rockers of a child's cradle), are fixed on the bottom angles, and to these the floor-boards are nailed. These pieces being painted black, are scarcely seen on the outside. The bodies of open four-wheeled carriages, as a barouche or a britzschka, must be made stronger, with iron plates at the bottom, than those of a close carriage, which requires none.

The variety in the forms of bodies is considerable, and chiefly characterizes the kind of vehicles. Open bodies have this advantage, that three persons can sit with tolerable ease on the same length of seat as would accommodate only two in a close carriage. A full-sized seat for a close body to contain three persons is about four feet two inches; that of an open body, three feet five or six inches; the seat in a close carriage for two persons is three feet five or six inches; in an open body, two feet eight or ten inches. The width across the seat is never regular, but generally from fourteen to eighteen inches; the height of the seat is usually fourteen inches. The height inside the body varies; from the top of the seat to the roof from three feet six inches to three feet nine inches, or more.

6556. *The doors* are framed double to admit of the glasses sliding down between the two thicknesses; in the best carriages the hinges do not appear on the outside. It is important that the doors should fit well; should they stick a little by swelling at first with the wet, it is best not to be in haste to have them reduced, as they will probably shrink in warm weather so as to be too little. The windows are of plate glass, for strength as well as appearance. The glasses are enclosed in frames of wainscot, covered with cloth or velvet. The door handles are of brass or of plated metal, generally plain, but sometimes richly chased in dress carriages.

6557. *Venetian blinds,* for excluding the sun in hot weather, and yet admitting the air, are added; and shutters of mahogany in panels, for shutting up the windows and excluding dust, are necessary when the carriages are not in use.

6558. *The steps* are made of iron to fold up double or treble, according to the height, and fill recesses in the insides of the doors when they are closed. They are covered with carpet or morocco. When fixed outside, care should be taken to place them conveniently, as they are often unsightly and in the way. When they are small and fixed, they are called *treads.*

6559. *The lining of the insides* of carriages was formerly always of light-coloured cloth, but now various kinds of silks are likewise used, and sometimes morocco. In summer this is occasionally covered with chints. The lining is ornamented with coach lace, fringe, tassels, &c.

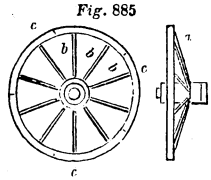
6560. *The seats inside* are strained over with cane or girth web, and upon this are laid cushings stuffed with horse-hair. Under the seats are placed portable boxes for holding things.

6561. *The floor* is covered with a carpet fitted in.

6562. *Pockets* are fixed to the insides of the doors, and also in front in chariots.

6563. *The wheels of a carriage* consist of the nave, spokes, and felloes. The *nave* is the short block of wood, nearly cylindrical, forming the centre of the wheel, *a*, *fig.* 885, and pierced by a hole for the axle to pass through. It is usually made of elm, but fustic has lately been used as a superior material. The *spokes* are the arms, *b b*, of oak, extending from the nave to the external rim, the several pieces of which are called *felloes* or *fellies*, which are made of ash or beech, and are hooped round and protected with iron, called the *tire*. This iron is either in several pieces, called *strakes*, or in one piece, put on heated; the last is the best way, as the iron, by shrinking in cooling, compresses the wheel, and binds it very tight; all carriage wheels are now made in this manner, which is termed *hoop-tire*, or *bond-tire*. Wheels are constructed in a form said to be *dished;* that is, the nave is not in the same plane with the rim or felloes, but falls back, so that the spokes form a very flat cone, as may be easily seen by viewing a wheel on the edge, as *d*, *fig.* 885. This is done for strength, and to throw off the mud and prevent it from clogging; it requires very skilful workmen to make good wheels; if bad, they often break down; and yet the men must be trusted for the work, for frequently no eye can detect bad workmanship. Wheels have been made wholly of iron, but though these answer in some cases for railroads, the elasticity of wood is found to be preferable in ordinary carriages and roads. The height of wheels varies.

Fig. 885



Mr. Adams observes, that, on a level ground, a horse will draw a vehicle with the greatest facility when the centre of the wheel is a trifle lower than the point of draught, viz., the point where the traces are affixed to the collar; but this in practice would be found inconvenient, inasmuch as you would be unable to enter the vehicle save from behind, and, moreover, the height of the axle would necessitate a corresponding and inconvenient height in the seat. For this reason, the total height of the wheels of two-wheeled vehicles is usually made to vary from three feet to four feet six inches. It must be borne in mind that a low wheel on a very level road, a railroad, for example, may be more efficient than a higher wheel on a rough and uneven road. But on the same road, and with an equal load, the high wheel is that which requires the smallest amount of power to turn it. The number of spokes varies according to the size of the wheel; there are two to each felloe; hind wheels have usually from seven to ten, fore wheels from seven to nine. An extensive manufactory has lately been established in Pimlico, London, for making wheels by machinery; and it is said that the wheels produced there are of a very superior quality.

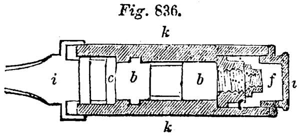
6564. *The axles* of carriages were formerly made all of wood, whence the old name axle-tree, but they now always consist of iron; the best are formed of several flat bars welded together, about two inches or two and a quarter in diameter for a coach; for light carriages an inch and a half. In common axles, the wheel is prevented from coming off by a pin, called the *linch-pin*, passing through the end of the *axle-tree arm*, the name of the part that the wheel turns upon; but as many serious accidents have happened through the linch-pin falling and the wheel coming off, an improved method of securing the latter is now practised, by means of a box, called the *axle-tree box*, which is contrived to answer the double purpose of keeping on the wheel, and to hold oil, grease, or some lubricating substance for lessening the friction. When iron axles were first used, it was the custom to drive a strong and broad iron hoop into the nave to prevent its being worn, and this plan is still used in heavy carts. The projecting seam formed in putting it together helps to secure it from turning on the nave. The commonest axle boxes now used for carriages are somewhat of a conical form, of plate iron, with a seam, as above, driven into the nave. At the upper part of the axle-tree arm the axle is left square, and against this a broad iron washer is driven or put to hold fast by shrinking; against this the axle-tree box works.

6565. To secure the wheel from coming off, an iron collar, called the *axle-tree nut*, is placed on the small or outer end of the arm, and through this and the axle arm the linch-pin passes. To hold the lubricating grease better, the inside of the box is sunk into hollows.

To prevent friction in wooden axles, soap or black-lead are the best materials; for common, coarse axles, a thick, unctuous grease is the best adapted; but for iron axles, which are accurately made and fitted to the boxes, there is no lubricating substance equal to oil of the purest kind, and freed from mucilage or gelatin, according as it may be of vegetable or animal production.

6566. Various patents have been taken out for axle boxes, but the most esteemed is Collinge's. This possesses the advantages of being very durable, giving a steady and silent motion to the wheels, and retaining the oil to prosecute a journey of 2000 miles without requiring to be replenished. *i* (*fig.* 886) is the axle-tree arm, made as perfectly cylindrical as possible, and of a peculiarly hard surface, the middle reduced in diameter so as to form a recess to contain the oil necessary to feed the axle-trees at the two bearings, *b b*, having a shoulder, *c*, against which the wheel-box, *k k*, takes its bearings; the adjoining collar is grooved for a washer to preserve the oil, and to prevent noise in its use, with a rim on the collar of the axle-tree. The end *f* is double-screwed, to receive two nuts for securing the wheels; one screw turns the way of the wheel, the other the reverse, and is meant as an additional security. *l* is a cap which covers the nut and receives the waste oil: it is made of brass, and screwed on. In order to ensure greater durability and greater freedom from friction, these axles and their boxes are always case-hardened, and the rubbing surfaces highly polished. These axles, excellent as they are, however, Mr. Adams observes, are not without their defects. Should, by any carelessness, the surface be suffered to be without oil, they fit so close that they would become hot by friction, and stick fast; likewise, should the smallest quantity of grit get in, it would cut into the metal and prevent motion. A patent has been taken out by Mr. Mason, which, according to Mr. Adams, remedies these defects. It is sometimes objected to Collinge's axles that, if any accident happens to them, such as a wheel sticking fast in the country, or on the Continent, their complication renders it a difficult matter to put them to rights. But this objection, observes Adams, is not of much force; for, if necessary, common boxes for grease may be applied to them as easily as to any others.

Fig. 836.



6567. *The pole* is applied when the carriage is put to use. It is fixed in the chops of the futchels, and secured by an iron pin. At the front end of the pole is a double staple, to which leathern straps called pole-pieces are attached, to hold the horses in proper position, and to prevent the carriage from overrunning them when descending a hill.

6568. *The coach-box* always forms part of a coach and a chariot, and also occasionally of some other carriages. The objection to it is, that it obstructs the view of the country from the front windows in travelling, and it is then frequently removed; but it is less fatiguing for the driver than when he rides one of the horses, and is also easier for the horse. The obstruction to the view is of less consequence in town. There are several kinds: the standard, the Salisbury, the travelling coach-box, and the chaise coach-box. The first two will be mentioned under "Boot;" the travelling coach-box, sometimes called a *dickey-box*, has a low iron rail round for the security of the driver; and the last resembles nearly a small chaise, in case the owner wishes to drive himself. The coachman's seat is stuffed with straw, and is covered with baize; it is made higher at the ends than in the middle, to give a more secure seat. This is covered by the hammer-cloth.

6569. *The hammer-cloth* is a constant appendage to the town coach and chariot. It is made of strong cloth stiffened with tarpauling, and is contrived to hang in large folds. The top and bottom are ornamented with bands of lace, and the bottom has, besides, a deep fringe. Some have a crest on the side.

6570. *The boot* is a box covered with black leather, placed on the fore part of the upper carriage for the purpose of carrying luggage. Boots are of various forms. Some are square, called platform boots, for holding trunks, &c., and then the coach-box is supported over it by upright standards of wood or iron; but that called the Salisbury boot is very generally used for town coaches; horns project upward from it, to serve as a support for the coach-box, and the coachman's foot-board is also a part of it. Formerly a kind of boot called the *budget* was very common in travelling-carriages for luggage. A boot behind, with a seat for two servants, is called a *rumble*.

6571. *Dashing or splashing frames* are fixed to the fore part of open carriages to keep off the dirt splashed up: they are made of leather strained upon iron frames (*fig.* 882) in the Tilbury. A curved sort has lately been introduced on each side of the body steps, to keep off the dirt from the wheels, borrowed, apparently, from the droitzschka. It is shown in the pilentum (*fig.* 866).

6572. *Lamps.*—In carriages, the term lamp is applied to the case or lantern that holds the light, whether that be given by a candle or oil. The simplest are wax candles contained in tubes, through a hole in the upper part of which the wick passes, the candle being pressed upward by a spiral spring as fast as it is consumed. In dress carriages, the lamps are circular and ornamental, and contain wax candles, though the light is inferior to that of oil. Lamps for travelling are square, with shutters for day to protect the glass: they burn oil with flat wicks, and reflectors of silvered metal are usually added. Means have not yet been contrived for using successfully Argand's lamps, as they are liable to be extinguished by gusts of wind, and the motion of the carriage causes the oil to overflow.

6573. *The iron* used in carriages requires to be of the toughest quality; the best is that kind called *king and queen*, which is prepared from fragments of old wrought iron collected and welded together. There is a large manufactory of it at Rotherhithe.

The irons are extremely numerous, and much of the strength of the carriage depends upon plates properly applied to the various parts. The springs have been already mentioned. The body loops, or iron brackets, bolted to the bottom of the body, one at each corner, to fix the suspension braces to, require to be very sound and strong.

6574. *On the quality of the leather* depends, frequently, the safety of the carriage; the *suspension braces* are made of several straps sewed together firmly. Besides these, there are *collar braces*, which go from the perch to each side of the body, to prevent it from turning over, and breaking the springs by a reverse action in case of violent concussion. There is also a *check brace* from the spring-beds to the body, to prevent it from swinging too far fore and aft.

6575. *Chaise heads*, used to most open carriages, are formed of hoops connected together by long iron joints, and covered with leather blacked and made water-proof. The fronts are round or square, with curtains to close it occasionally.

6576. *The painting and varnishing* of carriages are carefully performed. The body receives six or seven coats of oil paint; these, when dry, are rubbed smooth with pumice-stone and water, and two more coats are added; after that, it receives five or six coats of copal varnish, which, when thoroughly dry, is highly polished. This varnish is the hardest and least liable to be scratched. Adjusting the colours properly demands considerable taste. It is customary to confine the colours to the lower half of the carriage, except some stripes round the door and window; the remaining upper quarter is made black, a practice not ornamental, and which appears to have been continued from the time when it was the custom to cover all the upper part of the body with blacked leather. Heraldic bearings on the panels used always to be painted in their proper colours; now they are frequently painted in relief in nearly the same colour as the grounds. The carriage part and wheels receive several coats of oil paint, and are ornamented with stripes of various colours, to give a light appearance; they are then varnished with common varnish.

6577. *Carving* in ordinary carriages is sparingly employed, as it tends to harbour dirt, and impedes the process of cleaning; the timbers of the carriage are ornamented with a few sunk mouldings and small scrolls, to take off the plain appearance which they would have if left square. In state carriages more is introduced.

6578. *Carriage-building* is subdivided into numerous branches, and employs many distinct trades, only a part of which is engaged in the factories, as body-makers, carriage-makers, wheelwrights, axle tree-makers, smiths and spring-makers, curriers, brace and harness-makers, carvers, painters, japanners, lamp-makers, trunk-makers, blind-makers, lace-makers, ivory-workers, platers, chasers, embroiderers. Besides these, there are the manufacturers of cloth, glass, and other materials. In these various branches there are many skilful workmen, particularly the smiths and wheelwrights, some of whom receive high wages, and work by the piece; but few of them are in constant employment all the year. It is remarkable that the workmen consider themselves as of very different grades in point of rank, and the body-makers and wheelwrights stand at the head. It is generally admitted that the carriages built in England excel all others in point of lightness, strength, and goodness of workmanship; but we have been indebted to our neighbours for several hints in point of form.

6579. *In travelling*, several circumstances respecting carriages require to be attended to. If the axles of the vehicle are of the commonest kind, they will require to be looked at frequently, and have fresh grease every seventy or eighty miles. Collinge's patent axles will run from three to four thousand miles without fresh oil; but when they are to be fresh oiled, it is best to get a coach-builder to do it, except the servant has been taught and understands it perfectly. If the wheel runs dry, the axle gets damaged, and perhaps may break suddenly. The wheel-plate also requires greasing, and perhaps new leather to the transom. The suspending braces should likewise be examined, as the safety of the carriage depends upon them. Persons who suffer from the jolting of a carriage may sit on an additional loose cushion stuffed with horse-hair and wire springs, or on an India rubber one filled with air by means of a stop-cock.

6580. Though sometimes the same carriage is used for town and for travelling, and a town chariot may be converted into a posting one, yet there are some objections to this. Mr. Adams observes that "the springs adapted to a light weight easily are not adapted to carry a heavy weight, and *vice versâ*; and a carriage must lose much of its beauty when used for travelling. These disadvantages have prevented some from keeping carriages, and have obliged a few to keep two carriages. But another motive has perhaps been still more forcible. In travelling with a carriage rapidly, it is necessary to go with post-horses, or to travel by very easy stages with a single pair. Few persons like to travel slowly, and fewer still to leave their horses behind them, and be deprived of their use; and as the habits of those who keep carriages are mostly migratory at particular periods of the year, they would rather cease to keep horses and carriages than be confined to one spot. The desirable thing is to have one pleasure carriage perfect in all its parts, and to be able to convey it, servants, horses, baggage, and all, at a rapid pace, from one point to another, without injury to the carriage or horse; and to have the perfect use of it at any required spot with as much facility as though the owner had not left his home. This railroads will, in time, accomplish, as the carriage can be put on a platform, and conveyed with the steam vehicles, as well as the horses."

6581. *To preserve carriages* much care is required; and consideration should be paid to the various materials of which they are composed, which are as delicate as those of furniture. The coach-house should have a boarded floor, laid hollow, for the circulation of air beneath, and be extremely dry and well ventilated. It should not be placed, as is often the case, adjoining to stables, in the vicinity of dung-heaps, cess-pools, or open drains, as the gases disengaged from these places have a very injurious effect upon the paint and varnish. The wood-work is apt to swell with damp and shrink with heat, and, though it is well painted, yet the moisture will, in some degree, find its way in. If it be exposed in too dry situations, the panels will shrink, and perhaps crack; the wheels also require to be frequently wetted to prevent shrinking, particularly in summer. The iron-work is liable to rust with damp, which at last forces off the paint: the plated and brass-work tarnishes and suffers from the same cause. It is better to rub these dry every day than to suffer them to contract tarnish, which requires to be got off with whiting or plate powder. Leather requires frequent oiling to preserve its tenacity, which is particularly essential in those parts where great strength is required. Certain leathers, as heads and knee-flaps, where they are used merely to keep out the rain, are sometimes blacked or japanned, which answers for a time, so long as they do not crack; this saves a great deal of trouble in oiling, and has a good appearance. The cloths and linings of the inside should be kept free from damp, which will occasion them to rot from mildew, and the sun's rays will destroy their colours; but, above all, it is necessary, by frequent brushing and other precautions, to keep them from moths. To preserve hammer-cloths from rain, water-proof India rubber cloth covers are now used; and this has the advantage of keeping away moths, but the disagreeable odour prevents its being used inside.

After the carriage has been out, whether in the sun and dust or rain, it should be carefully washed and dried. It should, if possible, be cleaned before the dirt dries on it, and it should be well sluiced with plenty of water to prevent any sand from remaining, which might scratch the varnish in rubbing. Sea water should never be used. Great care in cleaning goes much towards the preservation of a carriage. The varnish of the body is very apt to be stained by the various substances in roads: the stains should be got rid of as soon as possible by rubbing with a baize or soft leather, and a little sweet oil, drying the place off with flour; or if the stains should be difficult to get off, a little rotten-stone or Tripoli, with oil, will assist. If the panels appear to begin to shrink, it will be proper to see that they are confined in their grooves, otherwise they may crack, which is a defect difficult to remedy; but this may happen without the framing giving way in the least. The wear of a carriage depends very much upon the coachman's driving, and looking after it when in the coach-house. He should have a knowledge of the construction of carriages, in order that he may know when any part is out of order, that the proper remedy may be applied in time. Driving very hard over the stones exposes the carriage to many accidents, and the springs and axle-trees are the parts most liable to give way: the wheels also suffer much. The shaking of the carriage frequently loosens the bolts and nuts; this should be attended to in time by the coachman, who, if he is skilful, may tighten them himself without always sending for the coachmaker; it is prudent, however, to try these once a fortnight, if the carriage has been in constant use. Rattling is a sure sign of something loose that requires to be tightened. When iron works against iron, rattling often takes place, and sometimes a piece of leather put between will stop it. Squeaking may be stopped by a little oil. Repairs, in general, form a considerable part of the expense of a carriage; on an average, the wheels require to be renewed every five or six years, or oftener if they are much used.

6582. *To have the use of a carriage* several methods have been resorted to. The most satisfactory mode is to have it built to order, as then it may be made to suit exactly the convenience and taste of those who require it. If the carriage is completely paid for at once, the owner takes upon himself all the trouble of keeping it in repair; but the carriage-builder will also let it upon lease for a term of years, generally four or five, engaging to keep it in repair all the time, excluding accidents: the occupier has thus the same advantages as with a ready-furnished house. When the term expires the carriage reverts to the builder. A third method is to purchase a carriage ready built; in this manner one may be often procured at a cheaper rate, but great judgment is necessary in the purchase. Few persons are judges of the qualities of a carriage so as to detect their faults; and, indeed, from the way in which they are sometimes got up on speculation, it is extremely difficult to discover the defects, except by a trial of some time. On this account, the safest mode is to pay a higher price, and trust the reputation of the builder. Carriages may likewise be hired for various periods, as by the week, month, or year.

6583. Some gentlemen who have carriages of their own job their horses, or hire them by the season or by the year. Careful job masters will stipulate for the employment of their own coachmen, but not always; it is for several reasons objectionable in a quiet family. It is important that every groom or coachman should be a competent judge of the working of a horse, that he may be able to inform his master whether he is properly served. A pair of carriage horses should be well matched; when this is neglected, one of them is obliged to do more duty than the other, and wears himself out; and it is likewise necessary that the carriage should not be too heavy in draught for the horses, or the horses too light for the carriage. Though carriages are in general made lighter now than formerly, yet some of the light kind have a great deal of iron about them. The fitting of the harness to the horses is likewise important to attend to.

BOOK XXIV.

OF STABLES, AND THE MANAGEMENT OF HORSES.

CHAPTER I.

CONSTRUCTION OF STABLES.

6584. Great improvements have been made lately in the construction of stables, since the nature of the horse has been so much studied by veterinary surgeons, and the importance of ventilation and good air has been understood, together with many particulars for the prevention of diseases of the feet and other parts. Formerly, horses were too often lodged in low, confined, and dark stables, where the air was of the worst description, in consequence of which diseases were engendered, the origin of which was unsuspected.

6585. *The situation of the stable* should be at some distance from the mansion, and it is best, if possible, to have a southern aspect to shelter them from the cold winds. It is desirable that the surface of the ground should be sloping, for the convenience of drainage, and that the soil should be dry, a damp situation being particularly injurious to the health of horses. It is essential that proper drains should be executed by the builder.

6586. *Stables should be sufficiently large* for the number of horses; but it is not judicious to have many horses in one stable, since the change of temperature occasioned by taking out some of them may render it too cold for those that remain. When there are many horses, it is best to divide the stable into several parts. For valuable horses, it is recommended that one stable should not have above six or seven stalls, or perhaps not above four or five. One empty stall is useful, that two may be occasionally thrown into one, in case of a horse being sick. For a pair of carriage horses, the stable should have three stalls. When there are many horses, the stalls are sometimes arranged in a double row, with a passage between, to occupy less space; but a single row, or a single-headed stable, is best; where it is double-headed, the horses are apt to hurt each other by kicking.

6587. *The walls* must necessarily be of the materials used in the country; but brick is the best, being the warmest and driest, if properly laid. The inside is usually plastered, or, at least, whitewashed. It should be boarded to the height of four or five feet, plaster being apt to break away; and all the stalls should be boarded at the head about three feet above the manger.

6588. *The width of the door* is usually three feet six inches, but this is too narrow for taking the horses out; four feet is better. The height of the door should be at least eight feet. Sometimes the door is usefully divided into two halves, one above the other. The bolts should be of wood, which is better than iron.

6589. *The floor of the stable* should be laid with materials that are durable, and of a certain degree of toughness, so as to prevent the slipping of the horses feet. Flagstones are not proper, except they are grooved or furrowed. Common bricks are not hard enough; but Dutch clinkers, laid edgeways, make an excellent, perhaps the best paving, being narrow and extremely hard. Basalt, called also whinstone, is employed in some parts of the country where it occurs, and is unexceptionable when squared to proper shapes. The asphalte forms a hard and even paving; it has been tried experimentally at the Veterinary College, and found to answer; it has also a very neat appearance.

To carry off the urine of the horses, the whole of the paving should be laid with a slope towards a channel or gutter running the whole length of the stable. But some object to the floor of the stall having this slope, as it is supposed to strain the back sinews of the horse, and they prefer making a grating in the centre of the stall (section, *fig.* 889), towards which the floor has a slight inclination, and a short drain from this should communicate with an underground drain, thus preventing the urine from remaining in the stable. Instead of an iron grating, some use a square piece of stone or oak with holes in it; this must be made to take up to clean the drain. If the floor of the stall is made to slope, the slant should not be above an inch in a yard. There must be proper traps to the drains to prevent any smells from rising, or cold air or rats ascending. The drain should lead to a manure tank. In stables where there is no contrivance to carry off the water, part is soaked up by the litter, part sinks into the floor, and the remainder evaporates and mingles with the air, rendering it damp and foul. Where the situation of the stable is a perfect flat, it is proper to raise the floor above the level of the surface, so as to get sufficient inclination for the drains and secure perfect dryness; the approach to the door may be a very gentle ascent.

6590. *The ventilation of the stable* is the next thing of importance we shall consider, since, if this is not provided for in the construction of the building, it is not easy to effect it properly afterward. Before the subject of physiology was rendered popular, and the nature of respiration understood, by which the necessity of pure air for health is rendered evident, people never thought of admitting fresh air into a stable, as they had no notion of its use. In fact, they did all they could to exclude it, by closing up every aperture by which a breath of fresh air might find admission. The horse was confined in a sort of hot-house, the air of which was so offensive that it was with difficulty the grooms could bear it. The bad effect of hot stables is now pretty generally understood, but still many do not know the difference between common air simply heated and air heated and mixed with other noxious gases. Those persons confound a hot stable with a foul one, whereas one might exist without the other, although the two qualities of being overheated and being foul with noxious air are generally united.

We would recommend the reader to study what we have said on the subject of ventilation; he will then perceive that the atmosphere which we breathe, when deprived of its vital principle through the act of respiration, whether of men or horses, is unfit for the support of life, becoming noxious, and, in fact, a poison, which, when mingled with the rest of the air, renders it unwholesome. It is necessary, therefore, to get rid of this foul air, so that it shall not be respired again, and to introduce fresh air that possesses the property so essential to life. But merely heating the air, without breathing it, does not deprive it of this vital principle, and air may therefore be warmed to a considerable degree without being at all unfit to be breathed. As, however, the foul air that comes from the lungs is always warm, this expired air is one of the chief causes of the high temperature of stables in which horses are confined, and in this case air so warmed is rendered unwholesome. It is as necessary that horses should breathe pure air as human beings, and that the gas which is ejected from their lungs should pass out of the stable, while, at the same time, an equal quantity of pure air is introduced into it. Fortunately, this noxious air, being lighter than the cold air, rises at first to the ceiling, and when proper apertures are made there for its escape, it will find its way out, while cool and fresh air will force its way into the stable at the lower part to supply its place.

6591. *The air of stables is not only deteriorated by the breathing of the animals, but it is farther contaminated* by emanations from the body, as well as by the noxious ammoniacal vapours arising from the urine and dung. This may be easily perceived on entering the stable in the morning, when not only an oppressive, but a pungent ammoniacal smell is perceived, resembling that of hartshorn, of which, indeed, the urine of the horse contains a large quantity. These vapours are hurtful to the lungs of the horse, and still more particularly to its eyes, and are no doubt the source, frequently, of blindness and many of his diseases. The grooms, likewise, are known to suffer in their health from the ammoniacal vapours in the stables.

6592. *The most effectual mode of managing the ventilation of a stable* is by having large trunks or tubes of board, about a foot square, to pass through the ceiling and roof into the open air, having their tops covered in such a way that the heated air can go out but no rain come in. If it is impossible to send them out through the middle of the ceiling, they may be carried out just beneath it through the wall; and it will be best if there be a tube to each stall, as at *a* in the section, *fig.* 889; or windows with luffer-boards, to be opened or shut as may be required, may be placed at convenient situations.

It is to be observed that no air can go out except an equal quantity be admitted to supply its place, as the stable must at all times be equally full of air; therefore, apertures for the admission of fresh air should be made somewhere at the lower part of the stable, where the draught will be least prejudicial. In a small stable, the bottom of the door will do for this, if a board be placed below the aperture in it, slanting so as to direct the current of air that enters upward, instead of its coming horizontally, which might strike upon the legs of the horses. In larger stables, where more fresh air is required, numerous small apertures are better than one large, placed in such manner that the air cannot reach the horse as cold currents, which may be injurious to him; they should be so contrived that the air admitted may soon mix with the rest.

6593. It is customary in the morning to open all the doors and windows to ventilate the stable when it has been shut up all night; but this, though often useful and proper when the horses are out, is not enough; for means should be provided by which a continual slow change of air may be going on, and which should act of itself, without any attention from the groom or his assistants, and yet that the change should not be so great as to render the stable cold. When the ceiling of the stable is flat, its height should be nine feet for four horses; and if there are more, it should be higher, as much as twelve or fourteen for large stables. The smallest ought not to be less than eight feet high. If too lofty it will be cold; when too low, currents are occasioned by the ventilation.

In a late number of the "Journal of the Agricultural Society," a method is described of correcting the bad effects of the ammoniacal vapours mentioned above as so injurious. If a mixture of powdered gypsum, wetted, and sulphuric acid (oil of vitriol) be strewed on the floor of the stables, the acid will neutralize the ammonia, and, to use the words of the grooms, "the stables will be sweetened." It has been supposed that the gypsum produced part of this effect, but it does not appear that any portion of the ammonia is absorbed by it, and that it merely acts as a convenient surface for the acid; for a mixture of sawdust and sulphuric acid answers the same purpose. One part of sawdust will absorb three parts of the acid solution, which should consist of one part by measure of acid and fifteen of water. Instead of strewing the mixture on the floor, where it will get mixed with the straw and injure the horses' feet, it is better to place it in trays distributed in various parts of the floor. The acid should not remain unchanged longer than three or four days, when it will be found neutralized.

6594. *The temperature of the stable* is a circumstance that requires particularly to be attended to. Grooms, in general, have a predilection for warm stables. Well-bred horses require a warm and genial temperature in the stables, supposing, of course, the air to be pure, to maintain that beautiful appearance of a glossy coat so indicative of condition, and so essential to the beauty of the animal. But although it has this effect, a very glossy coat in winter is not desirable; nature has a tendency to proportion the degree of fineness of the coat to the season, making it a little rougher in winter than in summer. The glossiness of the coat should be more the result of careful grooming than of the warmth of the stable. The bad effect of hot stables is evident from the diseases frequently occasioned by taking horses out into the open air, particularly in cold weather, when the temperature is 30° or 40° below that of the stable. This is often the cause of rheumatism, catarrh, or inflammation of the lungs, when horses are kept standing long in the cold, notwithstanding that exercise keeps them warm for a time. It is also generally known that a sudden return to hot stables is nearly as dangerous as the change from a heated atmosphere to a cold and biting air. It is true that the horse is an animal now in a highly artificial state, requiring to be treated with a degree of care beyond that of any other domesticated quadruped; but it is only the race-horse, and those with much of their blood, and particularly while in training, that require an extraordinary degree of warmth, since they belong to a race that came originally from a warm country; neither ought they to be kept too warm after they have been so long accustomed to our climate. No horse in the stable should sweat under his clothing; by so doing, he is rendered highly sensible to external impressions from alteration of temperature, producing a morbid sensibility of skin, and, consequently, a greater susceptibility to many diseases; it also proves a relaxant.

The heat of a well-regulated stable in summer should not vary from between 60° and 65°; nor in winter much from 50°. Some have even found the advantage of accustoming horses to a cooler atmosphere by keeping them much in the open air. It is essential, as we have already stated, that grooms should learn to distinguish between merely *heated* and *foul* air; at present they confound these under the name of *close*. But, as we have stated, air may be warm without being in the least unwholesome, and may be cold, and yet very foul, the wholesomeness for respiration not depending upon the temperature, but upon the gases which compose it and the noxious vapours with which it may be contaminated. The temperature should be ascertained by a thermometer kept in the stable.

As an argument against the practice of keeping stables too warm, it is stated that in Berwickshire it is not uncommon to keep horses all winter in hammels or small sheds in open straw-yards, where they are exposed to the freest circulation of air, and that they have no grease, swelled legs, coughs, or inflammations, or other diseases probably brought on by the use of hot stables. Horses, however, to be treated in this manner, should be brought up to it, for it would not be safe to try the experiment on a horse long accustomed to a warm stable.

6595. *The light of stables* has been much neglected. Many have not even a glazed window, as it has been supposed that horses had no use for light, and even that they thrive best in the dark; but this is now known to be an error; besides, a certain degree of light is necessary to enable the owner to see whether the stable is kept properly clean and in order. Some stable-keepers prefer darkness, to conceal their want of cleanliness, or to make the horse look lively when brought into the light; but this is injurious to his eyes. However, too much light prevents his sleeping.

6596. *Windows should be placed high up in the stable*, that the light may not come into the horses' eyes; and the glass should be in imitation of ground glass, to keep out the direct rays of the sun. When opened in summer, a net should be kept across the opening, as that keeps out the flies, so annoying to horses.

6597. Whitewashing or lime-whiting the walls and ceiling of the stable is very proper on account of cleanliness; but, except the stable is rather dark, it is best not to make the walls quite white, but with a tinge of brownish-yellow or stone colour, this being less glaring for the horses' eyes.

6598. *For night, the best lights are candles, or lamps in lanterns.* The gas lights, which are sometimes employed to burn continually in stables, are extremely prejudicial, as they consume much of the vital part of the air, and sometimes suffer the carbonated hydrogen to escape unburned, which is exceedingly injurious.

6599. *Stalls.*—All good stables are divided into stalls, one for each horse, and these are separated from each other by wooden partitions (see plan of a four-stall stable, *fig.* 887, and the view of the interior, *fig.* 888). If horses are placed together, they are apt to do each other mischief, or are in some way inconvenient to the other. In some stables they are separated only by wooden bars; but these are not enough, for one will sometimes rob the other of his food, or do him harm by biting or other annoyance. Good stalls require to be six feet wide in general, and should be eight or nine feet in depth; that is, the partition should be of this length to prevent one horse interfering with another; the height of the partition should be seven feet at the head and five at the heels. Ponies will do with stalls five feet wide, but large dray horses require six feet six inches. When the stall is too broad, the horse will stand across it; when too narrow, he cannot lie down, which is a necessary position for his repose after having been hard worked. It ruins a horse's legs and feet not to allow him to stretch his

Fig. 887.

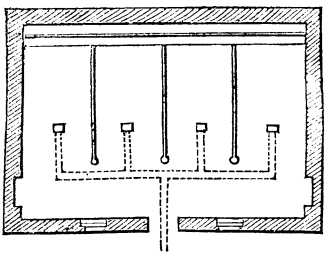


Fig. 888.

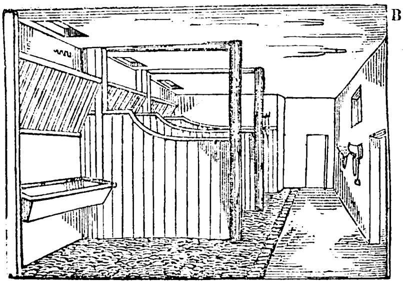
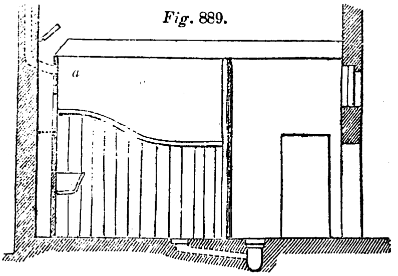


limbs in the stall. Of the paving of the stall we have already made mention. The stall posts are uprights at the bottom of the stall to stay the partition (see *fig*. 889); they should be round or octagonal, not square; sometimes they only rise a little above the partition, and sometimes they extend to the ceiling, which is firmest. Each side of this post should have a ring for pillar reins, which are used when the horse is required to stand reversed in his stall, as he is occasionally when being cleaned. The top of the partition is generally covered with iron.

Fig. 889.

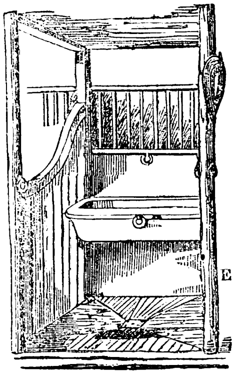


In some stables there are, besides the stalls, some compartments much wider, called boxes, for such horses to be in that are ill, or which require much rest. When horses are worked daily, it is proper to hang the harness of each on pegs in the wall opposite, to lose as little time as possible in putting or keeping in the harness-room that which is used only occasionally.

6600. *Hay-racks* are usually made of wood, but they are now beginning to be made of cast iron, which, though more expensive at first, are much more durable, and are more easily kept clean. The front of the rack usually slopes forward, as in *fig*. 888, that the horse may draw the hay more easily from it, and that it be more easily filled. But there are some objections to this form, and dust and seeds of the hay sometimes fall into the horse's eyes, and on this account some prefer having the bars or spars (as they are called) perpendicular, as in *fig*. 890; but this requires greater depth of the stall, because a partition must be run up at a little distance from the wall, as in the section, *fig*. 889, and the hay is thrown into the space between, either from the hayloft above, or from an opening just under the ceiling of the stable. In this space, below the rack, there is a bottom with bars closer to let the seeds and dust fall through, which are collected by a door below.

The spars should be round, two feet and a half high, an inch and a quarter thick, and two inches and a quarter apart. Each rack should have a ring at bottom for securing the horse's head: when tied to the spars, he is apt to bend or break them. Some have made the spars turn round on a pivot to facilitate the coming out of the hay. The racks are also sometimes placed in the corner of the stall, forming the quarter of a circle, which gives more room.

Fig. 890.



The usual mode of filling the hay-rack is from the hayloft over the stable, as it is generally in towns, by means of an aperture in the ceiling just over the rack, *fig*. 889. These apertures have been objected to; it has been said that the foul vapours from the stable rise up from them and contaminate the hay, and that the dust and seed of the hay fall down upon the head, mane, and ears of the horse, and, in consequence, it is recommended to abolish these apertures, and to keep the hay in another manner. But the rising of the foul air can be prevented by close trap-doors, and the dust may be avoided by a canvass sheet, to be used whenever the hay is put down. Any other mode of carrying in the hay would occasion much trouble, and in case of having perpendicular racks, as in *fig*. 890, no dust could occur. In towns, where space is so valuable, no place could be found for the hayloft so convenient as over the stable.

6601. *The manger* is the trough in which the horse's corn is put. It is usually made of wood and fixed, see *fig.* 888, but is sometimes also of cast iron and moveable, as in *fig.* 891; these have the advantage of being not only more durable, but of being likewise sweeter and cleaner, particularly where boiled or moist food is used, in which case wood imbibes the moisture and gives out a musty smell. Wooden mangers are made as long as the stall is wide, but iron mangers need not be so long; about three feet is sufficient length; they are generally nine or ten inches deep, but a foot would be better; and they should be twelve inches wide at the top, and nine inches at the bottom, inside. If the manger is too small, the horse is apt to scatter and throw his food out in turning it over. There should be no sharp corners to it for the horse to hurt himself against. Wooden mangers would be better if made moveable, so that they might be taken and scoured occasionally; but they should be securely fixed by draw-bolts. The top of the manger ought to stand from three feet to three feet six inches from the ground; if too high, the horse cannot eat comfortably, and if too low, he is apt to get his foot into it. It would be well to put sloping boards from the front edge of the manger to the wall, to prevent the horse cutting his knees against the corners. In the case where the rack is perpendicular, and there is a partition detached from the wall, as in *fig.* 889, the manger might be a drawer to slide back into the empty space. A small sheet-iron japanned drawer by the side of this might be made to serve as a water-trough, to move out on a pivot into the corner of the manger; but this must be made to lift out to be cleaned, or some other contrivance may be adopted for holding water in cases where it is desirable that the horse should always have it in his stall.

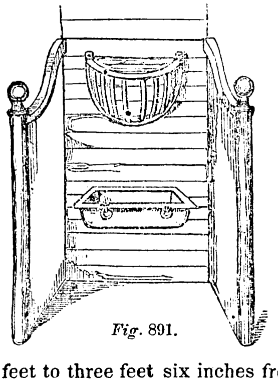


Fig. 891.

There are mostly two rings placed, one on each side of the manger or stall, for the reins of the horse's halter to run through, and a logger is fixed to the ends of these sufficient to poise them perpendicularly, but not so heavy as to tire the horse or to hinder him from eating.

6602. *Besides the daily cleaning out of the stable*, it should be thoroughly purified once or twice a year, by all the wood-work being scrubbed with soap and water, and the walls and ceiling whitewashed or limewhited; but opportunities for this should be taken when the horses are out for some time.

6603. *The hayloft* in towns is generally over the stable, chiefly for the convenience of supplying the racks easily: in the country it is often in another situation. Where there is no plastered ceiling to the stable, the joints of the flooring boards should be ploughed and tongued, and otherwise made quite tight, to prevent any noxious effluvia coming through from the stable. If the apertures for supplying the hay-racks in the stable have also close-fitting covers, this situation of the hayloft above the stable may not be objectionable; but in the country, where the hay can be cut from the stack every twenty-four hours, a separate hayloft is scarcely necessary. When there is one, it should contain nothing but the horse's food, and should be provided with means for ventilation. In large establishments, an adjoining room, for cutting hay or straw, bruising corn, and measuring, weighing, and mixing, will be found necessary.

6604. *A granary*, in a large establishment, or a *corn chest* with divisions for different kinds of grain in a small one, may be placed in any convenient situation that can be found. If above the stable, the grain can be supplied to the manger by a wooden tube.

6605. *Boiler-house.*—In a small establishment the boiler may be placed in a corner of the yard, but where there is much preparation of mashes, &c., sometimes a room on purpose is necessary to perform the various operations in, and for keeping all the implements belonging to the stable.

6606. *Water.*—At some places in the country there is a pond for watering the horses, but this water, though it may do to wash the carriage, or for the ducks and geese, is not fit for the horses to drink, being both dirty and stagnant, and, in cold weather, too cold. Water for drinking should be of the best quality, and should be kept near the stable.

6607. *Stable-yard.*—In towns, where the stables and coach-house are in lanes called mews, there is no place to groom the horses and wash the carriage but the mews itself; but in the country, where space is not so valuable, there is usually a stable-yard for this purpose, where all the wet work should be done. It may be well, likewise, to have a shed at one side of the yard, where the horses can be groomed in cold or wet weather, and where they can be moved about occasionally.

6608. *Stable appointments* are generally known. The *Dutch collar* and *neck strap* are necessary for every horse in the stall. *Muzzles* are also sometimes useful, to prevent a greedy horse from taking food from his neighbours or biting. *Dressing cloths* are of leather, hair, woollen, or linen. Combs, brushes, scissors, foot-baths, and stable pails are always required.

6609. *Harness-room.*—Though in confined places the harness is usually hung up in the stable or in the coach-house, yet, where it is possible, and where there is much harness, it is best to have a place on purpose. The stable is an unfit place, being damp and apt to spoil the harness, which requires to be kept very dry and clean. The harness-room should be well aired, and have a fire-place, be provided with proper pegs to hang the various articles of harness on, and it is a good plan to have a curtain to draw over them, to slide with rings upon a rod, to keep off the dust, which saves much trouble and time in cleaning; the walls behind where the harness is hung being boarded, and not plastered only: there should be, also, stools and shelves for saddles and various other articles, and cupboards for brushes, brooms, sponges, cloths, bandages, and such things as are in constant use: nothing of this kind should be suffered to lie about in the stable, but be so arranged as to be always at hand. It may also have a chest for keeping corn, and likewise a boiler for heating water.

6610. *Room for the Coachman or Groom.*—Where there are valuable horses it is proper that some one should sleep near, to be ready in case of accident in the night, but this must vary according to the nature of the establishment.

6611. *Furniture of the coach-house or stable:*

Coach mops,	Curry-combs,	Dung-baskets and boxes,
Jacks for wheels,	Inside brushes,	Stable shovels and forks,
Horse brushes,	Birch and heath brushes,	Rugs for gigs, carriages, &c.,
Spoke brushes,	Mane and trimming combs,	Corn sieves,
Quarter brushes,	Scissors and pickers,	Quartern measures,
Water brushes,	Oil-cans and brushes,	Whipcord,
Crest and bit brushes,	Harness brushes,	Horse blocks,
Dandy horse brushes for dirt,	Leathers for carriages,	Stable pails.

CHAPTER II.

ON HORSES AND THEIR MANAGEMENT.

6612. In the following pages we shall confine our observations to carriage and ordinary saddle horses, omitting racers, hunters, and farmers' horses as not coming within the scope of this work; and we shall devote our attention chiefly to those circumstances of proper management which are necessary to keep horses in health in the stable and at work, without entering into the treatment of diseases, which we leave to veterinary practice. We shall, in short, endeavour to select all those facts which it is proper that every one possessing horses should be acquainted with, but intending this rather as a check upon the pretended knowledge of those who may have the immediate care of horses; for no written directions can completely supply the practical skill of an experienced groom, to whom, however, the sole management should not be implicitly trusted, where it can be avoided. With this view, the most able writers on the subject have been consulted, and the various details have been compared with the opinions of several experienced persons.

SECT. I.—GENERAL REMARKS ON THE VARIOUS BREEDS OF HORSES.

6613. The horse, no doubt, existed originally in a wild state, as it does now in South America and Tartary, but at what period it was subjected to the dominion of man cannot be determined. All the civilized nations of the ancient world of whom we have any historical records not only possessed this animal in a domesticated state, but set a high value upon it, bestowing great pains in training and improving its various breeds or races. The origin of those breeds is likewise unknown, but they were most probably produced by the circumstances of variety in climate, food, and shelter, during a long succession of ages, assisted afterward by the effects of domestication in different countries. Climate has great influence upon the forms of animals, and, in general, a species is found indigenous to each country whose form best fits it for supporting its existence there. Thus, in the arid plains of the East, where herbage is scarce, the horse is found to possess a form which enables it to transport itself with great rapidity from one spot to another, without permitting his weight to cause it to sink in the sandy deserts. In wild countries, on the contrary, his size is diminutive, but his compactness and strength, as well as his coarse, shaggy coat, enable him to resist the severity of the weather. In temperate climes, where these causes do not operate, and where vegetation affords, by its luxuriance, more nutriment, we no longer see him equally small or slender, but, with great capacity still for progression, possessed of more beautiful proportions, with superior muscular power; varying considerably in his qualities, which are adapted to the purposes of war, hunting, parade, the saddle, and draught.

6614. The indigenous horse of every country has been modified by cultivation, and the native breeds have at one time or other been more or less mixed with other varieties with a view to improvement. What is meant by purity of blood is the result of limiting the propagation of particular races, and preventing other races from mixing with them. The native races of some countries are distinguished and esteemed above others for their peculiar qualities: thus the fleetest horses *are found in Arabia*, where they possess a spirit and courage united to docility excelling that of any others, and where they are brought up with an unexampled degree of care.

6615. *The Barb*, the *horse of Barbary*, is superior to the Arabian in point of form, and is remarkable for his free and graceful action, but is rather lower, and has not quite the speed and spirit of the Arabian: he has contributed much to the excellence of the Spanish and other European horses. Several varieties, having considerable resemblance to these, are met with in Tartary, Turkistan, and Persia; but the native breeds of India and China are much inferior. It is remarkable that horses were unknown in America before its discovery by the Spaniards, and that the wild horses, so numerous in the Pampas, are merely the descendants of some that got loose and escaped from the Spanish army.

6616. In Europe *the horses of Turkey* are descended chiefly from the Arab, crossed by the Persian and other bloods; they have contributed much to the improvement of our English breed. The German horses are, in general, large, heavy, and slow; but the Hungarian are an exception, partaking more of Eastern blood. The Dutch and Flemish horses are large, strong, and beautifully formed: we are indebted to them for some of the best blood of our draught horses. France contains, like England, numerous breeds of horses; but they are in general inferior to ours, though much attention has lately been paid to them by importing other breeds. The best French horses are bred in Limousin and Normandy, and from the latter district comes a strong variety, excellent for the cavalry, road, or carriage.

6617. *The earliest record of the horse in Great Britain* we find in the Commentaries of Julius Cæsar on his invasion of this island, in which he described the war-chariots of the Britons as being drawn by numerous horses. What was their original character is not mentioned; but probably they were subsequently somewhat changed by the introduction of Roman horses, which were themselves compounds from various countries. It appears that English horses were much esteemed even in the Anglo-Saxon times, but received a cross from those of William of Normandy. So early as the reign of Henry II. the value of the Arabian and Turkish horses was understood; and every successive monarch has bestowed much attention in improving the nature of an animal so useful and so great a favourite as the horse. Every variety of Eastern as well as European blood of a superior kind has been ingrafted on ours; and the advantage of this method is evinced in the high esteem in which English horses are now held all over the Continent.

6618. *Horses may be divided into draught and saddle horses.* Although our object in the present work is to confine ourselves to those that are employed for what may be called domestic use, namely, saddle or riding and carriage horses, yet a short account of the various other kinds of English horses may not be irrelevant. Saddle horses may be reduced to the race-horse, the hunter, the hackney riding or road horse, the Galloway, and the pony. Draught horses are the heavy draught horse or dray horse, wagon, coach, chariot, and gig horses.

6619. *The English race-horse* possesses his most valuable qualities of great speed in consequence of his descent from the Arabian, Persian, or Barb. The term of *thorough-bred* has reference to his origin, but it is not perfectly definite: it is generally supposed to mean that both sire and dam can be traced to Eastern parentage; but it may be considered doubtful whether many of our race-horses can be proved to belong strictly to this class. The "Stud Book," which is the chief authority for the pedigree of horses, traces all the most famous racers to some Eastern origin; or it traces them back to a certain extent, ending with a known racer the origin of whom is lost in obscurity; but it is supposed by some that several of our best racers are derived from our native horses improved by judicious crossing. A horse is said to have *blood* when in his pedigree it can be shown that he has derived his origin in any degree from a thorough-bred horse. If he has been produced by a racer and a common mare, he is called *half-bred*. Horse-races were very early among the English sports, and though at first pursued without any direct view to the improvement of the animal, they have ultimately proved useful by drawing the attention of the wealthy classes to the subject, and by preserving the purity of blood, or practising judicious crossing. By the most nutritious food and duly-apportioned exercise during his training for the courses, not only his speed, but his bodily powers, have been increased, and a breed of horses has been produced unrivalled in the world for symmetry of form, swiftness of progression, and durability under exercise. The Darby Arabian was the parent of our best racing stock. He was purchased by Mr. Darby at Aleppo, and was bred in the plains of Palmyra. His immediate descendant was the Flying Childers, so called from his breeder Mr. Childers, of Devonshire: the fleetness of this horse was so great that he moved over a space equal to 83½ feet in a second; some say a mile in a minute. After him, Eclipse, Highflyer, Matchem, Hambletonian, and others have contributed to keep up the reputation of the English racer, which has been known to beat some of the best of the Arabian breed on their native ground.

6620. *The hunter* is produced from a thorough-bred, or horse of entire blood, as it is called, and a mare of good quality; or sometimes from a mare of blood and an English horse of the best kind. This variety of the horse is, therefore, a combination of the speed of the Arabian with the strength and durability of the native animal, and the English breed is now much esteemed in every country of Europe. The real hunter is kept in the stable, and is attended with great care: the principle of training, or preparing him for his work, which is an affair of considerable time and difficulty, is the same with that of the racer, viz., to get rid of all the superfluous fat and flesh without too much lowering the animal; and particularly to bring him, by dint of exercise, into good wind, and accustom him to the full trial of his powers, without overstraining or injuring him. Occasionally it happens that a farmer's horse, worked in the day, with a feed or two of corn, and turned out at night, with an open stable or shed to run into if it pleases, is nearly as active and enduring, for one day's sport, as those which are carefully trained and confined to the stable during the hunting season; yet, if tried for a day or two, he will infallibly show an inferiority in wind and bearing fatigue, though he will much better resist the severity of cold weather than the pampered and stabled animal. It is a remarkable fact that both the racer and hunter fully share the enthusiasm of the rider. Without whip or spur, he will generally exert his energies to the utmost to beat his opponent; and several instances are mentioned where his natural ardour has been evinced in the struggle; even when, after hard work in racing, he has been turned into the park to enjoy himself for life, he has been known to feel an irresistible desire of joining in the chase on hearing the distant cry of the hounds.

6621. *The old English hackney*, now little known, was the origin, with improvement, of our best saddle horses, whether for the road or farmer. He has been frequently considered as indigenous, although it is most probable that the breed has sprung from a judicious culture of the small native horse with Norman, German, or Flemish, and thus improved in size and strength for the purpose of carrying hacks, for which the horse was formerly employed extensively.

6622. *The improved hackney*, *road-horse*, or *roadster*, besides the advantage of being, in all probability, partly descended from some of the best horses of the Continent, has also frequently some of the blood of the racer, but less of that than the hunter; and the proportion he should have will depend upon the kind of work he is to perform. A very good road-horse is even more difficult to meet with than even a hunter, for which there are several reasons. The price of a hackney, or horse of all work, is so low, that he who is so fortunate as to possess a good one will not part with him on account of his real utility and the little chance of procuring another equal to him, for it is by mere accident alone that he is to be obtained. He must likewise be free from certain faults that may be overlooked in the hunter. The latter may start; may be awkward in his walk, or even in his trot; he may have thrushes or corns; but if he can go at a good slapping pace, and has wind at bottom, we can put up with him or prize him; but the hackney, if he be worth having, must have good fore legs and good hinder ones too. As safety is required in the hackney as well as speed, great pains are taken to breed him so as to have the fore parts high and well placed, whereas in the hunter the hind parts are rather of most importance. The hackney must be perfectly sound on his feet; even-tempered; no starter; quiet in whatever situation he may be placed; not heavy in hand; and never disposed to stumble. The Irish road-horse is an improved variety of the English; and it is said that most of the common road-horses used in England are of the Irish breed. *Cobs* are a thick, compact variety of hackney breed, about fourteen hands, in great request for elderly and heavy persons to ride, or to drive in low phaetons.

6623. *The large black horse* is a noble animal that furnishes those grand teams we see in the coal wagons, and also in the flour and other heavy carts and wagons about London, where the immense weight of the animal's body assists his accompanying strength to move the heaviest loads. He is mostly bred in the midland counties of England, chiefly in Lincolnshire; but the present system of farming requiring horses of less bulk and more activity, better adapted for travelling, and more capable of enduring fatigue, he is confined chiefly to the above uses. This heavy breed is supposed to be derived from the old English black cart, improved by crossing with Dutch and Friesland mares. The largest of them are used as *dray-horses*. The next in size are employed as *wagon-horses;* and a smaller variety, with more blood, constituting a considerable part of our *cavalry*, is likewise devoted to undertakers' work.

6624. *The Cleveland or Yorkshire bays* have long been celebrated as one of the best breeds in the island for draught; but they are said to have degenerated of late. They are reared to a great extent in Yorkshire, the farmers of which county are remarkable for their knowledge in everything that relates to horses. In activity and hardiness they have, perhaps, no superior. Some capital hunters have been produced from the mares and full-bred stallions; but the chief object latterly has been to breed coach-horses and others for heavy draught, and these are of considerable strength. They appear to have been the origin of our best kind of heavy coach-horses.

6625. *The Suffolk punch* is a horse much esteemed for agricultural labour, being strong and active, but without any superiority of shape.

6626. *The Clydesdale horse* has long been in repute in Scotland and the north of England, and, for the farmer, is probably equal to any other in Britain, being docile and steady. The origin of this breed is uncertain; and they have not got this name from having been bred only in Clydesdale and Lanark, for they are reared in many other parts of the west and south of Scotland. They are rather larger than the Suffolk punches, and their colour is black, brown, or gray, with a white spot on the forehead. They are remarkably true pullers, and are seldom restiff.

6627. *The coach-horse* cannot be called a particular breed; but the origin of the superior kind is the Cleveland bay, confined principally to Yorkshire and Durham, but now difficult to meet with in either county. The coach-horse most in repute, with his arched crest and high action, is the produce of a Cleveland mare and a three fourth or thorough-bred horse of sufficient substance and height. From the thorough-bred of sufficient height, but not of so much substance, we obtain the four-in-hand and superior curricle horse. From the half-bred we derive the common carriage horse and the poster. Yorkshire is considered as the chief breeding county in England for coach-horses, hunters, and hackneys. The English coach-horse is now very different from what he was fifty years ago. We no longer see those clumsy black family horses, over-fat, straining at first starting, yet scarcely equal to six miles an hour, and knocking up with one day's hard work. Rapid travelling is now so much the fashion that the modern coach-horse is, with improved strength and action, frequently like tall, strong, overgrown hunters. Yet, though their speed is increased, they still have not the endurance that could be wished, and a pair of poor post-horses will often beat them at the end of the second day. It is remarked that no country produces finer horses than England, yet in no other country is there such a destruction of the animal from the rage for fast travelling.

6628. *Galloways.*—The true Galloway is a beautiful variety of horse, so called from that province in Scotland from which it came originally. It is a bright bay or brown, with black legs; but this breed has now become rare, from being neglected, on account of its unfitness for agriculture. The term Galloway, however, is now applied to any horse of the same size, which is between that of the pony and the pack, and such horses are much in request for drawing low chaises, for which the original breed is very valuable, being flat and very sure-footed.

6629. *Ponies* are the smallest of our breeds, not above thirteen hands, and they vary in different districts. The Welsh pony is a beautiful little animal, will live on almost any fare, and is never tired out. The Highland horses are very similar, being small, but remarkably hardy and enduring; and as they appear to be the same with those of Norway, it seems not improbable that they might have come originally from Scandinavia. They are seldom above twelve hands high, and sometimes only nine. They are extremely well formed, but inferior to the Galloway.

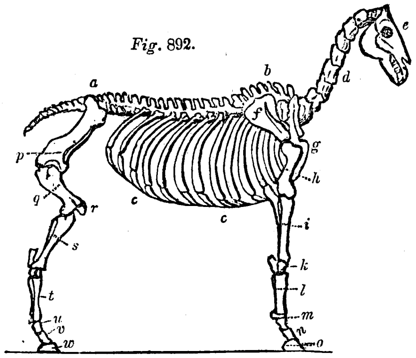
6630. *The Shetland pony*, called *Sheltie*, an inhabitant of the Shetland Islands, is a distinct breed, and the most diminutive of our horses, being sometimes not seven and a half hands high, and rarely exceeding nine and a half. He is a most hardy animal in his native place, subsisting on what he can pick up in that barren country without any sheltered habitation, and often, even in winter, obliged to find his own food by scraping off the snow, or resorting to the shore to eat sea-weeds, his body covered with long hair, and his mane and tail rough and shaggy. His strength is immense, and one will carry a man and his wife for miles to church on a Sunday. He is well formed, and perfectly docile. When transported into England, and submitted to the process of the curry-comb and the care of the groom, he becomes one of the most beautiful of the species, and may sometimes be seen harnessed to a low gig or chair in some of our parks. Several of them are now running in Windsor Park.

SECT. II.—NAMES OF THE EXTERNAL PARTS OF A HORSE.

6631. For want of knowing accurately the names of the various parts of a horse, mistakes are often made in giving or receiving directions, or in conversing about them, by those who have not been much used to horses. In order to understand these clearly, it is necessary to have some knowledge of the bones, and we therefore give a wood-cut of the skeleton, and another of the external figure of the animal, both to the same scale. To show the utility of the former, the reader may try to understand the horse without it, and he will then perceive the use of adding this farther elucidation; but we shall commence with the skeleton, *fig.* 892.

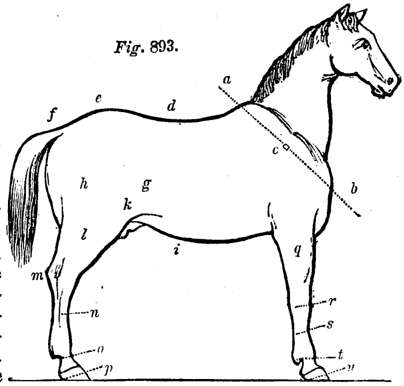
6632. *In the skeleton we may observe: a b* the *spine*, or back bone, composed of a number of joints or vertebræ, of which there are eighteen in the back, called dorsal vertebræ; six at the loins, termed lumbar vertebræ; five at the pelvis, or haunch, called sacral vertebræ; and from eight to thirteen caudal vertebræ, forming the tail. At *b* are several processes or projections from the vertebræ, just above the shoulder, which form what is termed the *withers*. It is to be observed that similar processes, though not so long, project from all the vertebræ, and that it is those which appear as a sharp ridge on the back of a lean horse. *c c* are the ribs, which are attached to the vertebræ of the skin, and in front to the sternum, or breast bone, *g*. *d* are the vertebræ forming the neck, and named cervical vertebræ; these are by farriers called rack bones. *e* is the scull. *f* is the scapula, or shoulder-blade. *h* is the humerus, or arm bone, so concealed by strong muscles as to be overlooked by the general observer; and in consequence the next bone, *i*, is commonly called the arm bone, which is anatomically the radius. *i* is the fore arm of horsemen, but the radius of anatomists. *k* is the knee, but answering to our carpus or wrist: the knee joint is formed of seven small bones. *l* is the cannon or shank bone, forming what is generally termed the leg; but it is to be observed that anatomists, in comparing the structure with that of the human body, consider this single bone as in the place of our metacarpal bones, or those of the palm of the hand, as if all our metacarpal bones were united into one. *m* is the upper pastern bone; *n* the smaller pastern bone. *o* is the coffin bone. These bones of the foot will be afterward described more at large. *p* is the haunch, consisting of three portions, the ilium, ischium, and the pubis. *q* is the femur of anatomists: this articulates with the pelvis, and its strong head is called the whirl bone. *r* is the patella, a small bone, called by farriers the stifle. *s* is the thigh bone of horsemen, but the tibia or leg bone of anatomists. *t* is the leg bone of horsemen, but the fibula of anatomists. *u* is the upper or larger hind pastern. *v* is the lower or smaller hind pastern. *w* is the hind coffin bone.

Fig. 892.



6633. *The following are the names of the external parts of the horse, fig.* 893. The whole is divided into the head, neck, trunk, and extremities. The head and neck are, in general, sufficiently well known; but we may observe that the line of the face is sometimes nearly straight, but occasionally a little arched. *a* is the withers; *a b*, the line of the shoulders extending from the withers to the breast, *b*, in front. It is by the muscles of the shoulders chiefly that the horse draws, and by which the action of the fore limbs is effected. The shoulder is formed by two bones, the shoulder-blade and humerus or arm, which are covered and concealed by large muscles; *c* is the centre of action of the shoulders. The humerus is the bone which, among anatomists, corresponds to our own, and it articulates with the shoulder-blade (see *fig.* 892), although among horsemen the bone below it is called the arm. *d* is the back, which extends from the withers to the loins. *e* is the loins, at the hinder part of the saddle, when that is on. *f* is the croup, extending from the loins to the setting on of the tail. The flank, *g*, is the part between the ribs and haunches. *h* is the situation of the whirl bone of the farrier, at the hip joint, formed by the articulation of the pelvis bone with the true thigh bone of anatomists (see *fig.* 892), concealed by muscles, and only to be understood by reference to the skeleton. *i* is the belly. *k* is the stifle. *l* is the part called the thigh by horsemen. *m* is the hock, or the articulation of the thigh bone of horsemen with their leg bone; *n*, the leg of horsemen; *o*, the pastern; *p*, the hoof. In the fore extremities there are *q*, the thigh of horsemen; *r*, the knee; *s*, the fore leg; *t*, the fore pastern; *u*, the fore hoof.

Fig. 893.



Sect. III.—VARIOUS QUALITIES IN A HORSE.

6634. *The height of a horse is measured by hands*, each hand being equal to four inches. The height of hunters and hackneys varies from fifteen to seventeen hands, but is never below the former; most usually between fifteen and sixteen, which makes them about five feet high from the point of the shoulder to the ground. Cobs are from fourteen to fourteen hands and two inches; Galloways are from thirteen to fourteen; ponies are not above thirteen hands; Welsh ponies sometimes not above twelve.

6635 *Horses are usually broken and trained* at four and a half or five years old, but not before; at five they are, in general, considered fit for full work. A horse is generally reckoned in his prime when from seven to ten years of age.

6636. Horses are not injured, but rather strengthened by plenty of work, provided it be not too hard, and that they are well fed; but they should not be much worked too soon, and before they have arrived at their adult state, as this is apt to bring on premature old age. Few horses last more than twelve or fourteen years with constant work; and during that time it must be expected that they are unfit for work from sickness.

6637. *The extent of the horse's life* seldom reaches much above twenty-five years, though with good usage they will live to thirty, and even to forty years. When very old they suffer much from decay of their teeth.

6638. *A horse's age is judged of chiefly by his teeth.* The horse, as is well known, has six incisive or nipping teeth in the front of his mouth, in the upper and under jaw; four canine teeth, called also tushes, and six molars, or grinding teeth, in each jaw above and below. The mare is without tushes, and has but thirty-six teeth, while the horse has forty.

The foal has six grinding teeth in each jaw at its birth, without front teeth; the tenth or twelfth day after two of the front teeth appear above and below, and in fourteen or fifteen days more the two intermediate come out, and the corner ones three months after.

6639. Various changes take place till the horse is two or three years old, when the front teeth fall out and give place to the permanent ones. At four years the horse has six molar teeth, and at five the tushes appear. Beyond nine or ten years the age of the horse cannot be ascertained with any certainty by his teeth, and previously to that time it requires persons of much experience to speak with decision on the age of a horse by his teeth. Breeders and dealers are known to practise various tricks with the teeth for the purpose of deception.

6640. *What are usually termed the paces of a horse* is his manner of moving. The ordinary paces are walking, trotting, galloping, and cantering; these are improved in the training.

6641. *To walk well* is a valuable property in a saddle horse, particularly to timid riders and to ladies. When a horse is tired by trotting a great distance, it may be a great relief to finish the journey by walking. The greatest speed in the walk of a horse is about six miles an hour, but five is the common pace.

6642. *Trotting* is either slow or quick. It is exceedingly difficult to mark the action of the horse's legs in trotting. The feet are lifted diagonally in the moderate trot; in the running trot, which is a rough pace, all the feet are in the air nearly at the same time. The speed of a horse in trotting may be improved by training, and it is of great importance in light carriages. Twelve miles an hour is reckoned a moderately quick trot; and fourteen miles in harness is good trotting. Eight or nine miles an hour is usual. This must, of course, vary with the description of work performed. The carriage of the horse's head is to be marked, both for grace and safety; it should neither be held too high nor too low; and there is sometimes a fault in his striking the hind with the fore foot.

6643. *Of the gallop* there are three varieties, that of full speed, the hand gallop, and the canter; the gallop at full speed is always preceded by the slower one, and at last is a succession of leaps. The greatest speed in galloping at the races has been a mile a minute.

6644. *The canter* is not a natural pace, but an artificial one, usually taught to ladies' horses, on account of the greater ease in the motion to the rider. In it all the legs are never in the air together, one of them always touching the ground.

6645. *Safety in horses is essential;* those which are apt to stumble are on all accounts to be rejected. Some horses that are safe in one pace will stumble in another: much depends upon good training, but much also on the rider. Horses that have been accustomed to mountainous countries and rough roads are generally safer and less liable to stumble than others. Some horses are apt to strike the ground too much with the toe, instead of lifting their feet clearly over obstacles, and should the fore part of their shoe touch a small stone, they may stumble, and even fall. In purchasing a horse, it is proper, therefore, to examine the front of their shoes and see if they indicate any marks of "tripping."

6646. *To decide respecting the action of a saddle horse*, the kind of work for which he is wanted must be considered. If it is for a lady, the canter is the most important pace; if for the road, then the trot is of most consequence: few excel in all the paces.

What is called *grand action* in horses is not desirable in those for the saddle, nor in those used for light carriages, or where speed is required, but is requisite only in horses for state carriages, and perhaps for the coach, the landau, the barouche, or cabriolet.

6647. *The colours of horses* are laid much stress on by many persons, and long experience has shown that certain tints are usually accompanied by certain qualities of person or disposition. As a general rule, dark-coloured horses are the best, but black form an exception, as they are extremely variable. Light shades appear unfavourable to strength and durability. *Bay* is a prevailing tint, and is generally admired; it admits of many shades; there are bright bays, dark and dappled bays; the latter is esteemed for beauty; brown bay is valued for service, and consists of bay and black in variable proportions: all bays have black manes and tails. *Brown* horses are highly prized; the dark varieties have sometimes beautiful tan markings. *Chestnut* is also a good colour, but is said to be less depended upon than some others. The *sorrel* is a variety of the chestnut, but not a favourite one. *Dun* is a colour that has several varieties, the mane and tail sometimes lighter and sometimes darker than the body, with frequently a black list along the back: they appear to be of all qualities. *White* horses are not in much estimation, neither is it a very common colour for young horses; but some become white through age. *Black* is a very usual colour, and seems to be an original tint. The tempers of black horses vary extremely, being either sluggish or too fiery. It is seldom that a horse entirely black is seen; there is usually some spot of white in the forehead, or a few white hairs on the breast. The *roan* is a mixture with white hairs. *Gray* horses are of many shades, compounded of black and white; there are the iron grays and dappled grays. Various other names for mixtures are enumerated, scarcely possible to define.

SECT. IV.—FOOD OF THE HORSE.

6648. The substances on which the horse is capable of subsisting, and on which he is actually fed in various parts of the world, are more various than might be generally supposed. Among these are enumerated, not only herbage, green and dried, with grain and pulse, but roots, fruits, leaves, and twigs of many trees, reed flags, and even milk in Arabia; and in steril countries animal matters, as dried fish, flesh balls, broth, eggs, &c. But the natural food of the horse is of the vegetable kind; and such of our readers as wish to be intimately acquainted with the chemical nature of vegetable food in general we would recommend to study our chapter on this subject, where we have treated at some length on the properties of the various kinds of grain and pulse, and other vegetable substances.

6649. *The feeding of horses* is a subject that demands much attention, and it is one, observes Mr. Stuart (to whose excellent work we are indebted for many hints), on which people unacquainted with stable affairs are apt to make many blunders, because they reason too much from analogy, and suppose that the rules by which they regulate their own diet should be applied to the horse, although he is an animal whose digestive organs are very different from those of man. "The large stomach of the horse being intended by nature for green food, requires a greater degree of distention for its functions than corn alone can produce; one use of hay, therefore, in addition to corn, is to distend the stomach: as a proof that nature demands this, if a horse is unlimited in his allowance of corn, he will frequently leave this to eat some fodder, or even the litter; therefore, when the usual fodder is too dear, some cheaper substitute must be found. The use of giving condensed food in the shape of corn is to enable him to do more work than he could do upon what is not so. From this the importance of attending to the bulk of the food will be understood. Hay and all kinds of green food and roots contain less nutriment in the same bulk than corn or pulse, and, therefore, the horse must eat a greater quantity of the former; but as this quantity encumbers the horse by its weight, bulky food is not proper for horses where speed is required. Food in the more condensed form of grain and pulse is fitter for fast work; slow or moderate work assists digestion; but such work as horses in general have to perform, and which sometimes produces copious perspiration, requires peculiar management. During fast work it is probable that digestion is suspended, or the stomach is not in a favourable condition for performing its duty. It is, therefore, not right to give horses a full meal immediately before commencing their work, if considerable; the bad effect of doing so is well known to experienced horsemen; the horse wants breath, and is unwilling to go forward; the action of his lungs is impeded, and he has to carry an increase of weight, which, though but a few pounds, has an effect upon his speed; on this account it is usual to feed coaching horses one or two hours before starting, and hay is withheld after the corn is eaten; but it is not proper to keep them from food so long before their work that exhaustion commences.

6650. *The food of horses in this country* is of three kinds: what is called *fodder* consists of grass and all kinds of green food, hay, and straw. *Corn* is a term applied to oats and every kind of grain and pulse upon which horses are fed. *Roots*, as potatoes, carrots, turnips, &c., form the third. The greatest nutriment in the smallest bulk lies in corn; the least in fodder.

6651. *Of herbage given to horses*, the principal kind with us is the extensive class grasses, which may be eaten moist or green, or dried into hay. When eaten moist while it is growing, the horse is said to *graze*; but when the green food is cut and carried into the stable to the horse, he is said to be *soiled*. By the latter practice he loses the benefit of the fresh air of the fields, but much time is saved to him, since, in grazing, he would require several hours to eat sufficient, whereas he could eat the same quantity of green food in his stable in one quarter of the time. Grass is the natural food for the horse; it is composed of a great number of plants growing together, and differing considerably in their properties; some of them are much relished by him, and he rejects others. Although in a state of nature he can subsist sufficiently well upon this food, yet when domesticated and applied to hard work, grass and other kinds of green food are not sufficiently nutritive to keep him in condition; and it is necessary that he should have also the farinaceous food which corn supplies to give him strength. Besides the common or meadow grass there are several species of grasses and plants which are cultivated for green food, as clover, rye grass, lucerne, saintfoin, &c., respecting the particular merits of which there are various opinions; but they appear all to produce nearly the same effects as meadow grass, some horses liking one best and some another; clover, rye grass, and tares are the most common.

Furz, called in Scotland *whin*, is, when green, a very good food for horses, which have often subsisted upon it when there was no other. It must be bruised by a bruising mill, and should be given with straw and oats. It is said that the British cavalry while in the Pyrenees, under the Duke of Wellington, had often no other forage.

6652. *Vetches*, or *tares*, take the lead as a green food for the soiling of cattle; and it is also made into hay while in a state of blossom. They are best for horses when the pod is formed.

6653. *Notwithstanding the good effects of green herbage occasionally, yet this must be given with caution*, since, accustomed as the horse is to an artificial state of living, it effects a considerable change upon him. For the first two or three days green food relaxes the bowels, and increases the secretion of urine and perspiration: if permitted to eat of it as much as he pleases, the belly becomes large, from the quantity of this kind of food required to satisfy him; but though corn gives him more strength than grass, yet his general health is much improved by the latter. When horses are *soiled*, they should never get much green food at a time, a practice too prevalent among servants. The custom of giving corn along with green food is unprofitable; for the grain, thus mixed, passes rapidly off from the stomach, and is never perfectly digested.

6654. *Pasturing Horses*.—We have stated that grass is the natural food of the horse, and it is the kind most conducive to his health. Horses worn down with work, disease, or bad food, are frequently sent out into the fields to renovate, and they are is then said to be "turned out to grass." Pasture fields differ considerably as to their situation, air, moisture, or dryness, and the species of grass that grow in them. Some are hard and injurious to the feet; others are too soft, wet, and marshy. Those on the sea-shore are by some thought to be peculiarly renovating, except they are occasionally overflowed by the salt water, and converted into marsh, when their salubrity is very questionable. It requires some judgment to determine when it will benefit a horse to send him to pasture, or whether giving him green food in the stable is preferable. The plants that form grass being of great variety, some of them are much relished by the horse, while others, though luxuriant and agreeable to the eye, are never touched by him, except there is nothing else to eat. He is, therefore, continually occupied in selecting those kinds which are most agreeable to him; this causes him to take a good deal of exercise, and the exposure to the air is, in general, favourable to health. It is remarked, that horses that have been long accustomed to the stable often have stiff necks when first turned out to graze, from the alteration in the position of the head when feeding; but this soon wears off.

6655. *In turning horses* out to grass, care should be taken to select favourable weather, and to inure them to the change from the warm shade gradually by letting them remain in the field at first only a short time, and by leaving off their stable clothing a little before going to grass. Spring is the season when the horse receives most benefit; the grass is sweetest, and most tender and digestible; sometimes it is even medicinal; he is then also less tormented with flies than in the summer, when the heat is often too great. The autumnal grass is much inferior, and perhaps may then be deficient in quantity, in which case he requires a supply of corn.

6656. *Hay* is grass cut during its flowering time, and dried. In making hay it is first spread out and exposed to the sun and air for a proper time, and then it is collected into large masses called ricks, when it is supposed that a certain degree of fermentation takes place, which fits it for being wholesome and nutritious, as well as for its preservation; it is afterward dried thoroughly. If suffered to remain too long in the rick, the fermentation proceeds too far, and it becomes heated, and is termed *mow burned*, when its nutritive properties are injured, and it acquires noxious properties. The quality of the hay is a matter of great importance to the health of horses, particu larly when they are fed much upon it.

Good hay should be a year old, and have a pleasant smell and taste.

New hay is laxative, and, though horses are fond of it, it seems not to be very digestible, since much of it passes through him unaltered. If the hay is too old, it becomes dry and tasteless; horses will scarcely eat it. It is said that the making of hay is performed more skilfully in the vicinity of London than elsewhere.

When hay is in the least mouldy, it should not be given as food. Sometimes hay is salted to prevent fermentation in the stack; the horse relishes the salt, which is supposed to assist the process of digestion; but it is not well to feed him long on salted hay. Grass, in drying, loses half its weight; and hay gets drier as it grows older.

Many horses thrive best on clover hay, particularly draught-horses, which are very fond of it. In the market it costs twenty per cent. more than meadow or rye grass hay. A horse can live on hay and water; and when not used for work, he often receives nothing else; but this food alone is not sufficiently strengthening: he then becomes feeble and pot-bellied. On hay and corn horses may be fed for a long time without inconvenience. When illness attacks them, soiling in some cases is resorted to as a remedy. In gentlemen's stables scarcely any other than meadow hay is admitted.

6657. *Straw is little used in England as fodder for horses*, but it is employed in many places on the Continent where there is little or no hay. It is sometimes given to farm-horses, but seldom to coach-horses, being less nutritious than hay. Oat straw is preferable to that of wheat, but that of barley is so poor and brittle as to be unfit. Some more nutritious and less bulky food may be added to straw when it is given.

The haulm of beans and pease, but especially the latter, when well harvested, forms a very hearty species of fodder. The stalk of the beans is tough and somewhat woody, and is seldom used, unless softened by being bruised, cut, and steamed. Pea haulm is succulent and nutritious, and is much relished by cattle; but it should be given cautiously, as it is apt to produce flatulency. It should not be kept so long as to grow musty.

6658. *Corn.*—Several kinds of grain are used as horses' food, varying in value according to the proportions of their chemical constituents. In Great Britain *oats* are the general horse grain. They contains seven hundred and forty-three parts in a thousand of nutritive matter. The oats should be nearly a year old. If new, they are more difficult to digest; and, when eaten in considerable quantities, are apt to occasion colic. Musty oats are very unwholesome. Oatmeal is sometimes made into gruel for horses that are sick. Oats give to a horse that masticates well great invigoration; but corn alone, if given to excess, predisposes the animal to fever, and to contract particular disorders, which often fall into the legs; and this effect requires to be counteracted by some means, of which the best is green food, many of the grasses partaking of some medicinal virtue or other, and a cooling principle: this is better than medicines. Upon the whole, oats form the most substantial and most useful food for saddle and coach horses, though this is always varied by some addition. Several substitutes have been tried, as barley, beans, pease, carrots, potatoes, and other roots; but though horses with slow work may do for a time with these, yet to all of them there is some objection not applicable to the oat.

Barley is rarely used in this country for horses, but is common food for horses and mules in the south of Europe, particularly in Spain; it does not appear to answer quite so well with us as oats, notwithstanding it appears, from chemical analysis, to contain a greater quantity of nutritive matter. Before the introduction of oats, it was much more used, and appears to have been the principal horse-food of the ancients. It should be sound in quality, and should be bruised or steeped before it is given. Barley is reckoned to cool the blood of horses, and is occasionally given to them ground in mashes, and mixed with chaff, for fattening them when they are recovering from illness.

6659. *Wheat* is rarely given as horses' food, except when farmers have a quantity that is not saleable. It contains more nutritive matter than any other grain. Horses eat it greedily; but it is difficult to masticate, and also to digest, from the quantity of gluten it contains, which is apt to form obstructions in the bowels. It should never be given alone, but mixed with chaff; and it is a good plan to bruise it or soak it in hot water. The external part of wheat is employed in all town stables, either as bran or pollard, the latter being the most nutritious; but these are more expensive than oats.

Rye is not employed here as horses' food, but is very generally used in North America, coarsely ground, and sprinkled over straw and clover grass previously wetted. It is also used in Germany, but generally in the shape of bread made from the whole flour and bran; and it is not unusual, in travelling through some parts of that country and of Holland, to see the postillions help themselves and their horses from the same loaf. The plan of giving wheaten bread to horses was formerly adopted on some race-courses in England, but was not found to answer.

6660. *The pulse used as horses' food* are beans and pease.

Beans are a very hearty food for draught-horses, but are seldom used alone, on account of their heating and astringent qualities. It is well known to travellers that they produce more vigour than an equal weight of oats; a horse can travel farther on being partly fed with them, and is not so soon exhausted. They should be at least a year old; when they are new they are indigestible and flatulent. If horses are old, their teeth are not able to masticate them, and then they should be bruised in a mill, or soaked. They are usually mixed with oats or bran, or with cut straw or hay.

Pease are seldom used alone, but mixed with beans or corn fodder. They are said to be more indigestible than beans. The variety of pea given to horses is the *gray* or *hog pea*, which is smaller than the garden pea.

6661. *Maize* is not used as horses' food in England; but in the West Indies saddle horses are kept in good condition by it.

6662. *The roots used as horse-food* are such as contain much sugar. *Carrots* are most esteemed, and are much relished by all cattle. They are slightly laxative at first, but this effect wears off when the horse gets used to them. They form an excellent substitute for grass; but though horses can work upon them, they cannot supersede corn. In combination with oats they are said to restore a worn-out horse, and to have an excellent effect upon the coat of horses. They may be given raw, being first washed and sliced; their nutritive property, compared with oats, is as six to four.

6663. *Parsnips* are very nourishing, and are much used in France for horses' food. They are used raw, and also boiled and mixed with cabbages, bran, chaff, or buckwheat.

6664. *Turnips* are sometimes given to farm or cart horses, but seldom to any other. They are not proper to be given in the raw state, but should be boiled, or partially steamed, and mixed with potatoes. The Swedish turnips are much better than the common.

6665. *Potatoes are very nutritious*, but should be always steamed. Professor Low states that fifteen pounds of potatoes yield as much nutriment as four pounds and a half of oats. They are sufficient occasionally for horses that do slow work, and they may for some time supersede the use of corn, even for those that do fast work. Horses eat them very readily. Raw potatoes are found to be extremely prejudicial, and in some cases they have even proved fatal to horses.

6666. It is to be observed that though farm-horses, and such as do slow work, may be kept in condition for a considerable time upon the above vegetables, with only half the usual allowance of corn, and sometimes without any, yet horses that have to do hard or fast work cannot be supported long without high feeding, with plenty of oats or other corn.

6667. *The usual way of feeding carriage, gig, and post horses* is nearly similar. The usual fodder is hay, not cut, in unlimited quantity. In the summer some grass is given, and in winter occasionally, perhaps once a week, a bran mash. They also receive three or four feeds a day, consisting of oats and beans, broken or unbroken, and uncooked, in quantity from twelve to sixteen pounds. The groom should observe whether the horse masticates his corn sufficiently; if not, it should be mixed with chaff, or be bruised.

6668. *Food for the manger is sometimes mixed.* Horses often waste much of their hay and straw by pulling them down out of the rack and trampling them under their feet. This is prevented by cutting them into chaff, which is often mixed with corn or beans. These the horse can thus masticate more easily; and he is also obliged to chew them instead of swallowing them whole.

6669. *Cutting the hay and straw into chaff* has several advantages; it is said to be more easily eaten than uncut hay, and saves time in eating. The trouble of cutting, and the expense of the machine for it, are objections where there are but few horses.

In Flanders it is the universal practice to convert the entire provender into manger meat, and their horses are generally in high condition. Some recommend, however, that a little uncut hay should be put into the rack, to give the horses employment, since when they have none they are apt to become mischievous.

6670. A great number of horses kept in towns receive nothing but oats and hay all the year round. Some add a little grass in summer, and roots in winter, with perhaps a weekly feed of bran; but others, whose work is more laborious, and often performed in stormy weather, are the better for a more complicated diet, containing beans, varied by barley, wheat, or rye, which may be boiled, and given once a day, or as a portion of every feed. But after a horse has been accustomed to a particular kind of food, it is not proper to change it suddenly, as this sometimes causes indigestion and colic; and, upon the whole, a spare diet is generally safest.

6671. *Among other substances used in mixed food* oil cake has been used in small quantity with advantage Sugar mixed with hay has been found to possess much nutriment. Milk and eggs have been given, but only under particular circumstances. Horse-chestnuts, it is said, would prove a useful article: in Turkey they are ground and mixed with other food. Figs and chestnuts are used in Spain and Italy; apples, occasionally, in France; dates in Persia: in short, any vegetables used by man, and possessing farinaceous or saccharine matter, will serve upon occasion as food for the horse.

6672. *Some kinds of food require a kind of preparation, or are improved by it.* Grain and pulse are often bruised by metal rollers. When the corn is to be made into gruel, it must be ground, but without separating the husks from the meal. When barley is used for horses whose teeth are bad, steeping is necessary; but malting is prohibited by the excise. Boiling is sometimes used for grain, roots, and pulse; but the advantages do not appear to be generally very obvious, as horses do not like liquid food; the food should be hard enough to give their teeth some employment; and food in its raw state appears to give them most vigour. Horses particularly dislike boiled food if cold, and they prefer it half boiled. Steaming is preferable to boiling, being more easily performed. The chief value of boiling or steaming consists in rendering the food more easy of digestion, and thus enabling the animal to retain a greater portion of its nutriment than when it is used in a crude state. For old horses, in particular, whose teeth are worn, it is very advantageous to have the food softened. But for young and healthy cattle it is thought that raw food gives most heart.

6673. *The quantity of food required by horses daily* varies with the kind of animal, his constitution and habits, and the work he is to perform. Large draught-horses will consume sixteen pounds of hay, four pounds of straw, and eighteen pounds of corn. The cavalry allowance of hay and oats in barracks is twelve pounds of the former and ten pounds of the latter, on which they are kept in high condition. Saddle horses have about ten or twelve pounds of oats, and more hay than draught-horses. More corn is given when they are in full work. Excess of food produces too much fat, but too limited a diet brings on greater evils. The horse loses flesh and strength, and is then liable to several diseases. But any considerable change should be made by degrees; one suddenly made from poor to rich food may bring on plethora, too great a fulness of blood, and surfeit.

6674. *Salt* is often given to horses; but the propriety of its daily use is questionable. Most quadrupeds appear to be fond of salt, but they probably seek for it only when instinct impels them to desire it as a remedy. It is a good practice to fix a piece of rock salt in the stable, which the horses may lick when they wish for it.

6675. *The times of feeding* must likewise depend upon the kind of work; but it is best for the horse to have regular hours, since he gets accustomed to them, and regularity is favourable to his digestion. Horses in daily work should seldom be allowed to fast more than three or four hours, and may be allowed a little hay between feeding-times. Upon the whole, abstinence, to a moderate extent, is not so prejudicial as much work upon a full stomach.

6676. *Water.*—Bad water is very injurious to horses as well as to human beings. Clear soft water is the best; if it be only a little hard, it may not be hurtful, particularly when the horse gets accustomed to it; but very hard water is improper, and is apt to disorder the bowels. Though cold water would seem to be the natural drink of the animal, yet very cold water, as that from a frozen pond, is not proper in his artificial state. It is generally carried into the stable in pails, and some let it remain there all night, covered up, until it is wanted in the morning; others add a little warm water to it; but Mr. Stewart observes that the practice of giving constantly "chilled water," as it is called, has a bad effect, rendering the horse so tender that he is injured by the cold water which he is obliged occasionally to take. Horses generally receive water three times a day; in hot weather they may need more. The quantity required by a horse in twenty-four hours is variable; one will drink more than another, and much depends upon their kind of work. He requires more with hay than with green food, and more when at work than when in the stable. It is doubtful whether a horse should have water always before him. In that case, probably, he will seldom take more than nature demands; but he should not, in general, be allowed to drink as much as he pleases at one draught; it is best to give it to him at intervals. It is generally necessary to hold it up to him in the pail, manger high, as some horses find it difficult to drink from the ground. Some patience must also be employed, and perhaps, occasionally, a little coaxing, to make him drink. Horses should not be allowed to drink immediately before going to work; during work they should have good allowance.

6677. *Clothing.*—Though horses for carriages and the saddle are kept in an artificial state, and require clothing in the stable, which is not necessary for those which are mostly out of doors, yet it is a common error to carry the clothing to too great extent, which renders them liable to take cold, particularly when their pace is to be slow, in cold weather. The change, also, from warm clothes to the saddle is often too great. Saddle horses should stand in the stable with only very light clothing, except in case of sickness. All horses, except racers, should be without clothing in the summer, or, at most, a thin sheet to keep off dust and flies.

SECT. V.—DUTIES OF THE COACHMAN, GROOM, AND STABLE-BOY.

6678. There is so much to be known about carriages and horses, that servants who have much skill respecting them are rare and valuable. In racing and hunting studs, the grooms employed have been regularly brought up to their business; but in small establishments the knowledge of a horse is less regularly acquired, and of course is less perfect. The coachman, besides his skill in driving, requires complete experience of the stable of which he has the management; he has to purchase the provender, see that the horses are properly fed and groomed, watch the condition of his horses, and report if anything is amiss. To the groom is committed the business of feeding and dressing the horses, for which practice and dexterity are essential. The stable-boy has usually much to do, and besides his immediate business in the stable, must readily turn his hand to whatever he is fit for elsewhere, and is always the better for good looking after, and not having much idle time on his hands.

6679. *The first duties of the groom in the morning*, which generally commences at six o'clock, a little earlier or later according to the work required, is to get the stable cleaned out and the horses fed. The hay should be put lightly into the rack, and a little after racking, as this is called, the usual feed of oats should be put into the manger. The morning allowance of water is usually reserved until after dressing, but sometimes horses refuse to feed except they drink first, and then a small quantity of water should be given. The stable-boy is next to clear away the dung and moistened litter, which should be done every day. The soiled litter should be removed, together with the dung, and none of these should remain in the stable all day. The floor of the stall should be thoroughly swept, even in the joints of the paving, whether bricks or stones.

The use of litter or straw spread over the floor of the stall is sufficiently obvious. It is to form a tolerably soft and warm covering to the naked stones or bricks with which the stalls are paved. It entices the horse to lie down, which relieves him if fatigued, and is favourable to the recovery of over-strained limbs; it also prevents an unequal pressure, which results from rough paving; it may likewise be proper to state that many horses will not stale readily on bare bricks, from the disagreeable effect of the urine splashing against their legs. But if too much litter be used, particularly in the day, some are of opinion that it is apt to heat the horse's feet, and cause a contraction of the horn of the hoof, as well as to make the legs swell; if not changed every day, but suffered to remain soaked with urine, it has a most prejudicial effect, from the noxious vapours that are engendered; and although, in well-managed stables, the litter is changed every day, yet still there is frequently great negligence in this respect among farmers and others. Formerly oak floors were used, with numerous holes to allow the urine to pass, but these are now seldom used here, though they are frequent abroad. The litter should be laid on smoothly, and with great care: wheat straw is the best material, and is mostly used in England; oat straw is softer, but is not so easily even, and is more apt to run into heaps. Bean and pea straw make very indifferent bedding. Where straw cannot be procured, other substances will do, as sawdust, wood shavings, dried tanners' bark, or leaves. Sawdust is very useful to sprinkle over the floor of the stable after it has been washed, to absorb the wet that lodges in the joints of the stones, and likewise prevents them from being slippery. The horses are next to be dressed, and, if the weather at all permits, this should not be done in the stall, but in a sheltered place in the yard.

6680. *What is called dressing the horse* is keeping the hair and skin in order by the use of the curry-comb, brush, and duster. The grooming or dressing a horse can never be learned by oral instruction, and skill must be acquired by imitation of an experienced person; nevertheless, the proprietors of horses should be acquainted with the principal points to be attended to, and it is these we propose to mention. Good rubbing not only clears off the loose dirt, but improves the circulation of the blood. The farmer's horse, that is worked all day and turned out at night, requires little more to be done to him than to have the dirt brushed off his limbs. With the stable horse the case is different.

6681. Currying causes the blood to circulate, opens the pores of the skin, and removes the scurf that accumulates and stops the insensible perspiration. The curry-comb separates and raises the matted hairs, and removes the hardened mud. Notwithstanding these uses, some consider the action of a good brush as producing a more beneficial influence upon the skin and hair; and certainly some grooms use the curry-comb with unnecessary harshness, the horse being seen sometimes to tremble with the pain. After currying, the horse should be well rubbed to take off all loose hairs, and then with wet hands till his coat shines like satin. The mane, foretop, and tail are next combed, and if the legs and feet are stained they are washed with soap and water, and trimmed with the scissors.

Cleaning the carriage has been already described.

6682. *Before the horses are put to the carriage* the brush and a cloth are to be passed over their coats to remove any dust; the wet sponge should be applied to the eyes, nostrils, and rump, and the comb put through the mane and tail. The shoes ought to be examined, the harness then put on, and the horses attached to the carriage.

6683. *While the carriage is out* the stable-boy cleans out the stable thoroughly; in a dirty stable myriads of insects are bred, which are very annoying to the horses.

6684. *On those days when the carriage is not going out*, the horses should be exercised for a couple of hours every day. At noon the horses are fed and watered, again sometimes at four o'clock, and at eight in the evening a little hay is put into the rack for the night.

When horses are much confined to the stable, their hoofs are apt to become dry, and crack; to prevent this, it is necessary to stop their feet occasionally during the night with some moist substance, such as a mixture of cow-dung with some loamy earth.

6685. *When the carriage returns home*, they should not be fed immediately if their work has been fatiguing; they should wait until they are cool. If fed too soon, particularly if they have fasted too long, it may produce indigestion. In such case, it is proper that they be first rubbed down and dressed. If they are heated, the water used to wash their legs should be lukewarm, and they should be walked about until the pulse is lowered before being put into the stable. It is desirable that they should never be kept too long without food, since this may cause debility, and they then, perhaps, eat voraciously or refuse to eat.

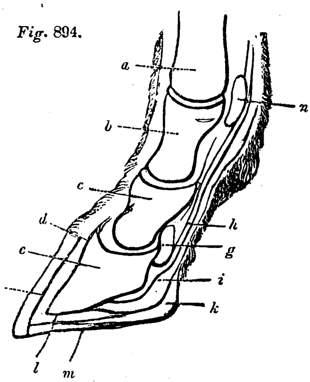
Sect. VI.—horse-shoeing.

6686. *No part of the horse is of more importance to be attended to* by the owner as well as the traveller than his feet, together with the shoes for their defence, and we select this portion of the subject for a more particular detail. Before paved and hard roads were made, probably no defences were contrived for the feet of the horse, and the first that were made use of appear to have been copied from those of his master. A sort of sandals are mentioned as occasionally employed by the ancient Greeks and by the Romans as late as Constantine, and these were stiffened by plates of iron, and sometimes ornamented with the precious metals. The injurious effects of fastening with thongs have given place in modern times to the present method of nailing on iron shoes; and Beckman states that the first account of the modern horseshoe occurs in enumerating the furniture of the Emperor Leo, of Constantinople, but it was not until long afterward that its use became general; and it was first introduced into England by William of Normandy. The art of farriery advanced, at length, into much consideration, and has made, at least, as much progress in this country as in any other.

6687. *To understand the principles of horseshoeing*, and to be able to reason correctly respecting it, it is essential that we should be acquainted with the outlines, at least, of the anatomy of the horse's foot. We shall therefore premise what we have to say on this subject by pointing out the chief anatomical parts.

6688. *Fig.* 894 represents the anatomy of the foot in a section. *a* is the lower part of the shank bone (see the skeleton, *fig.* 892); *b* is the *greater pastern bone*; *c* the *lesser pastern bone*, or *coronary bone*; *d* the *coffin bone*, or bone of the foot; *e* is an elastic process, or coronary ring of the crust; *f* is the *crust*, or outer wall of the foot or hoof; *g* the *navicular* or *nut bone*; *h* the back sinew, or great flexor tendon of the foot, binding over the navicular bone, and terminating in the coffin bone; *i* the *sensible frog*, covering the end of the flexor tendon; *k* the *horny* or *insensible frog*; *l* the *sensible sole*; *m* the *horny sole*; *n* the *sessamoid bone*.

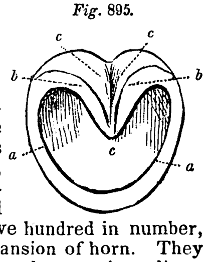
Fig. 894.



The coffin bone is of a light, spongy structure, and is filled with numerous holes for the passage of blood-vessels to the foot. The eminence in front receives the insertion of the tendon of the extensor muscle of the foot, whose upper attachment is to the humerus or arm bone, where it is fleshy, but as it passes it becomes tendinous, expanding over every joint. In the hinder limb this extensor and its two adjuncts arise from the tibia, and, in part, from the femur. To the sides of the coffin bone are attached the lateral cartilages, and around its surfaces are marks of the attachment of the laminated substance. The *crust* or wall of the hoof reaches from the termination of the hair to the ground. It is deepest in front, called the toe, shallower at the sides, called the quarters, and of least extent behind, at the heel. It is placed flat on the ground, but ascends in front with different degrees of obliquity in different horses, the most approved slope or slant being about 45°. In front it is rather more than half an inch in thickness, and becomes gradually thinner at the quarters and heel. As there is only half an inch hold for the nails of the shoe at the toe, and less at the quarters, horses are sometimes wounded in shoeing by ignorant or careless blacksmiths. The horn of the wall is composed of numerous straight fibres held together by a gelatinous cement. This crust, in some horses, is liable to be broken through brittleness, particularly in summer, and it is then proper to rub it with a mixture of oil of tar and common fish oil, to restore the pliancy. The horn of which the hoof consists is naturally kept moist by an oily secretion from the frog, otherwise it would soon crack and be deprived of its elastic power. The smaller pastern bone articulates with the coffin bone at its posterior part, and is connected by ligaments with the navicular bone. The upper portion is united to the shank bone in an oblique direction, which varies in different horses. The shocks in locomotion are broken by so many ligaments and tendons as unite these bones, and, in reality, render the foot stronger by their elasticity.

Some other parts of the foot are best seen by turning up the sole of the foot, as in *fig.* 895. The wall of the hoof, *f* in the section, and *a a* in *fig.* 895, instead of continuing round in a circle on the under part next the ground, is suddenly inflected or bent inward, forming what are called the bars, *b b*, which meet at the point *c* at the toe of the frog. These bars, by their softness and elasticity, serve to prevent the pressure of the horse's weight from injuring the frog and parts immediately above, and therefore the practice of those smiths is wrong who cut them away, as is often the case, and which causes the frog, deprived of its guard, to contract. The inside of the crust or wall of the hoof is covered by numerous thin, horny leaves extending all round it, and reaching from the coronary ring to the toe. They are about five hundred in number, broadest at their base, and terminating in the most delicate expansion of horn. They very much resemble the inner surface of a mushroom. In front they run in a direc-

Fig. 895.



tion from the coronet to the toe, and towards the quarters they are more slanting from behind forward. They correspond with similar cartilaginous and fleshy leaves on the surface of the coffin bone, called, from their construction, *sensible laminæ*, and, the one being received within the other, they form a most elastic body, by which the whole weight of the horse is supported. The inside of the bars, like the inside of the crust, presents a continuance of these horny leaves. The insensible frog fills the space between the bars. It is a triangular or wedge-shaped portion of horn projecting from the sole almost on a level with the crust, and covering and defending a soft and elastic substance called the sensible frog. The insensible frog consists of two rounded or projecting surfaces, *c c* (*fig.* 895), with a fissure or cleft between them. The frog is firmly united to the sole, and, by its softness and elasticity, coming to the ground when the horse treads, prevents him from slipping. The rough and detached parts only should be cut off in shoeing, so as just to bring it within the level of the shoe, but it should never be suffered to project without this level. In the unshod horse, as in the colt, it always touches the ground, but with our hard roads it would soon be worn away were it not for the defence of the shoe; it is quite essential, however, that it should come into contact with the ground sometimes, as want of pressure on the frog, which is sometimes the consequence of too high shoes, will bring on disease of the foot. The *sole* is the under concave and elastic substance of the foot extending from the crest to the bars and frog: it is not so thick nor so brittle as the crust, but is more elastic. It is thickest at the toe, and, to a certain degree, concave or hollow, but descends when the horse rests upon his foot. In shoeing, it should be but very slightly pared, so as to preserve this concavity. Sometimes a stone will insinuate itself between the sole and the shoe, and, if not removed, will cause lameness. The sensible sole, situated between the coffin bone and horny sole, is formed of a substance having a ligamentous or tendinous nature, and is plentifully supplied with blood-vessels; its use seems to be to secrete horn for the sole; it is highly sensible, and is apt to be inflamed by any injury, which causes corns and lameness. The *sensible frog* occupies the hinder part of the foot, and is a soft, elastic mass, partly ligamentous and partly cartilaginous, attached in front to the inferior part of the coffin bone. The navicular bone is a small bone which strengthens the joint at this part.

The reader having now a general idea of the structure of a horse's foot, will be able to understand the reason for the precaution pointed out in shoeing.

6689. *The injurious effects of bad shoeing* only require to be pointed out to excite every endeavour to avoid them, and the importance of shoeing is evinced by the great pains that have lately been bestowed on the subject. There are some circumstances in the common practice of country smiths which ought to be guarded against by every one who possesses a horse likely to come under their hands; but the shoes at present made by the most respectable smiths in the cities and large towns, and their mode of shoeing, are in general nearly unobjectionable. Many persons are very careless as to the state of the horse's feet and his shoes. The shoes are often worn till they drop off in the middle of a journey, and time is lost, the foot broken or destroyed, and, very likely, the horse lamed. If the horse be doing little work, perhaps the shoes are left on too long, and the horn is suffered to grow so as to accumulate too much; then the horse's action is fettered; he cannot step out; he cannot place his foot firmly on the ground, and he is very liable to corns. Hence at certain intervals the superfluous horn must be pared away; a month is the usual time; some may go five weeks. If the heels are weak or the seat of corns, the shoes may require removal every three weeks. If the shoes of fast workers are not worn at the end of a month, the feet should be pared, and the old shoes replaced.

6690. *The preparation of the foot for the shoe is a subject of much moment.* It is, of course, commenced by pulling off one old shoe; for it is better never to take more off at once, otherwise the horse is apt to break away the edges of the horn while standing on the bare ground or pavement. In removing the old shoes, which were fastened by nails clenched, great care should be taken by the smith to raise the clenches thoroughly, or file them off, until the shoe can be taken off easily, instead of wrenching them off with violence, as is sometimes done, by which the nailholes are enlarged, and the future hold weakened by portions of the crust being detached; and the horse shows by his flinching how much he suffers by this violent operation. When the foot is tender, or the horse to be examined for lameness, each nail should be partly punched out, and care should be taken that no stubs remain in the crust, the source of future annoyance. Next, the rough edges of the crust should be rasped, which prevents its breaking away when set down, and also detects any stubs of old nails left behind, and removes loose portions that would hold gravel, either of which might turn the nail that may be introduced there. The sole is to be pared throughout, until it can be what is called "thumbed," *i. e.*, felt to spring by a forcible pressure of the thumb. In this paring, the natural form of the arch of the sole should be as closely imitated as possible, and particular care taken that no part of it be left to protrude beyond the line of the crust; on the contrary, its concavity ought to commence immediately from the line of separation between the crust and sole, but not from the edge of the crust, as is sometimes done. The whole thickness of the crust, be it more or less, ought to be left perfectly flat for the bearing of the shoe. Habit, and a correct eye, can detect any inequalities in this surface, without a momentary application of the heated shoe to try the bearing parts, as is usually done, and which, if the shoe be also previously tried with a plane iron, may very well be avoided. Nevertheless, the outcry raised against this practice is, in a great measure, unnecessary for, unless the shoe be very hot, and held on too long, no harm probably results from its application. In common rough shoeing, also, this error is infinitely less than the application of the unequal pressure, which it is intended to prevent, would prove.

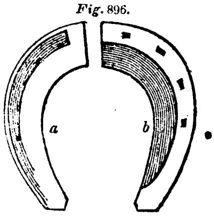
The portion of sole between the bars and quarters should be always pared out; and, if properly done, is the surest preventive against corns. The heels should be an object of great attention, and ought to be carefully reduced to the general level of position which it may be supposed the hoof was originally placed in, and which may always be judged by observing the line of the pasterns with it. It is of great consequence that the inner heel should not be reduced beyond the outer, for its natural weakness gives it a tendency to increased wear; instead, therefore, of paring both equally, in case the outer is the highest, pare only the outer; and, moreover, set the shoe very lightly on the inner heel. A want of attention to this circumstance of inequality in the heels lays the foundation of corns and splints.

6691. *The paring of the insensible frog* is an important part of the process; but it is highly improper to cut it much away, as is the practice of some smiths, particularly when employed by dealers to give an appearance of "opening the heels;" nor should it be pared too much, since it is intended by nature as a resisting prop to support the internal parts of the foot from pressure; it ought not, however, to be suffered to project too much. The most judicious mode is, instead of beginning with the frog, to attend first to the crust, sole, and heels, and then a mistake in paring the frog is less likely to arise; for it may be regarded as a general rule, that when the frog is a very little beyond the level of the return of the heels and the crust, it is as large as it ever ought to be; and the heels of the shoe will raise it up sufficiently for protection against too much wear, but will not elevate it against a proper share of pressure. With respect to the intermediate portion of horny substance that fills up the angle, it should be moderately pared out in every instance, for it is the seat of corns; and if accidental pressure alight and remain there, a corn is the inevitable consequence. If even a small particle of gravel should lodge here, each step forces it farther; and as soon as it has reached the sensible parts, inflammation and suppuration ensue.

6692. *Many attempts have been made to improve the form of the shoe,* and not entirely without success; but it must be observed that no form of this defence for the foot can be adopted as a universal pattern; and it is only by understanding the anatomy of the foot, and the defects and diseases to which it is liable, that the peculiar form can be devised, best suited to each animal. As a general principle, the form of the defence should be adapted to the foot, and the foot should not be altered to the shoe; yet, in some cases of diseased feet, even this rule admits of modification. The foot of an unshod horse expands as soon as it is placed upon the ground and has received its share of the weight of the body; but when such foot is bound within a solid rim of iron firmly round the horny crust, the expansion being thus prevented, reaction takes place, and turgescence of the blood-vessels, by which heat is evolved, and the horny segment so heated contracts its dimensions, and thus presses painfully upon the sensitive part, and disorganization is the ultimate consequence. To form a horseshoe, therefore, such as will protect the foot effectually, while, at the same time, it is left in full possession of its natural elasticity and expansive properties, has been the aim of many veterinarians and many ingenious smiths; but perhaps nothing has yet been contrived com pletely adapted to the natural action of the horse's foot.

6693. *The shoe now usually worn by hacks* is the seated shoe adopted by Mr. Clarke, of Edinburgh, Mr. Moorcroft, and others. *Fig.* 896 is the *seated shoe.* This shoe is represented in two halves, *a* and *b*. The half *a* represents the ground surface; its nail holes enter no farther towards the heels than is necessary to keep the shoe fast. The half *b* represents the foot surface, which is bevelled off, but not entirely to the heels, that there may be no invitation to the heels to contract, from an inward inclination of the quarters of the shoe. The nail holes of the toe portion are carried around the whole circumference, that portion of the horn being best able to bear the shoe pressure without producing contraction. Of course, this shoe may be modified various ways; it may be made wider or narrower, heavier or lighter, or it may be steeled to most unusual wear; but, as we before observed, no positive pattern can be fixed up adapted to all horses. A well-made seated shoe should present "a web" of uniform thickness throughout, and of a width sufficient to protect the foot; but both this and the thickness should be regulated by the size of the horse, the nature of his work, &c., but it should in all cases be sufficient to obviate the effects of occasional hard wear, or the accidental neglect of renewing. To an animal so strong as the horse, the additional weight of one or two ounces to each shoe is very inconsiderable; but this addition to the support and protection of the foot is very material in many cases; and a shoe rather stout is preferable, particularly where there is any tenderness of feet, or tendency to corns. Round the outer edge of this shoe there is a groove, called a *fuller,* in which the nail holes are punched, so that by sinking into the fuller their heads project but a little way, and are soon worn down level with the shoe. The ground surface of the common shoe used in the country is somewhat convex, instead of being perfectly flat as this is, and the inward rim of the shoe comes first on the ground; the consequence of this is, that the weight, instead of being fairly borne on the crust, is supported by the nails and the clenches, which must be injurious to the crust, and often chip and tear it. In the seated shoe there are five nails on the outer and four on the inner side, or four on the outer and three on the inner, because the outer has more thickness and strength to support the nails. The foot surface of the seated shoe presents a bevelled portion over two thirds of its extent, except at the heels, where it is partially plane on both surfaces, which plane portion is intended to receive the heels. This bevel, or seating, allows for the descent of the sole, which certainly does take place in a slight degree; but principally it favours the ejection of stones, &c., which, lodging there, might injuriously press upon the horny sole. The seated shoe is best suited to the flat-hoofed horse, and the shoe itself is rendered lighter by seating, without detracting from its strength. The smith will sometimes make difficulties respecting the making of the shoe; but these will soon be obviated by the owner of the horse declaring his determination to have no other, and paying a little more for them.

Fig. 896.

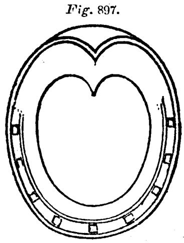


6694. *Clips* are sometimes useful additions to the shoes of horses used for heavy draught; these are portions of the upper edge of the shoe hammered out, and turned up to embrace the lower part of the crust. They attach the shoe more securely to the foot, and relieve the crust from that stress upon the nails which would otherwise be injurious. They are also necessary where horses are apt to stamp, or paw violently with their feet.

6695. *The shoes for the hind feet of most horses* are forged somewhat different from the fore shoes, being made a little squarer at the toe for about an inch; to which squareness the hoof, also, is to be adapted by rasping it slightly. For carriage and draught horses, *calkins* (a turning up and elevation of the heel) may be put on the hind shoes, to enable them to dig their toes more firmly into the ground, and urge themselves forward and throw their weight into the collar with greater advantage; but care must be taken that they are not too high, and that they are of an equal height on each heel.

6696. *The bar shoe* is described by Mr. Stewart as a very useful contrivance. It is the continuation of the common shoe round the heels, and by means of it the pressure may be removed from some tender part of the foot, and thrown on another which is better able to bear it, or more widely diffused over the whole foot. It is principally resorted to in cases of corns or other diseases of the feet; but it must be observed that these shoes are not safe in frosty weather, nor where great speed is required, and that they are apt to be wrenched off in a heavy, clayey country.

Fig. 897.



6697. *Tips* are short shoes, reaching only half way round the foot, and worn while the horse is at grass, to prevent the crust being torn by the occasional hardness of the ground, or by the pawing of the animal; and the quarters being free, feet disposed to contract have a chance of expanding and regaining their natural shape.

6698. *A strip of felt* or *leather* is sometimes introduced between the seating of the shoe and the crust, in cases where the foot is bruised or inflamed, which deadens the vibration or shock in moving, and is useful while the inflammation lasts, but should be removed afterward.

6699. *A piece of leather is also sometimes fitted to the sole* and nailed on with the shoe, in cases where the sole is flat and tender; but there is a great difficulty in padding this so firmly that it shall not become uneven, which would be injurious by giving unequal pressure.

6700. *Frost shoes* are very necessary, and have the heels turned up, the turned up part being made with an edge; calkins are apt to be soon worn, and are therefore insufficient.

6701. *The sandal shoe* is a very useful invention to supply temporarily the loss of a shoe until one can be procured. For want of a provision, horses' feet have been seriously injured in travelling over stony ground The best is that made by Mr. Percival, consisting of an iron shoe bound on with leather straps.

Sect. VII.—Hair of the Horse.

6702. Every spring and autumn the horse sheds his hair. Nature suits the thickness of his coat to the season. When winter approaches, the short hair of summer is cast for longer hair as warmer clothing; and when the summer heat returns, this is exchanged for a lighter covering composed of shorter hair. But as a sleek and glossy smooth skin is desired in the artificial state in which the horse now is, this natural change is counteracted by keeping the horse in warm stables, which has the effect of perpetual summer. The hair is not cast all at once, but comes out gradually; that of the mane does not change so rapidly, and that of the tail is always changing, a few hairs coming out at a time; the mane of carriage horses is made to lie on one side. It is the practice of grooms to pull out the hair from the inside of the ears; but this should not be done, as this hair wards off the entrance of insects and cold winds; neither should they cut off the few long straggling hairs that appear about the face, as they are a sort of whiskers to keep off flies.

6703. Some degree of trimming is generally necessary to all horses required to look well; but this demands a dexterous groom, as, when done, the marks of the scissors should never be visible. The practice of using them on the horse's coat should be avoided as much as possible, and it is only necessary where the coat is very long and rough. The hair of the fetlocks is generally trimmed short, which is done that the legs may dry quickly after washing.

6704. *Docking the tail* is very generally practised in this country, and is done partly through the inconvenience of the tail to the rider; but, as this member was probably given to keep off flies, the horse suffers much from the want of it when he is out at grass. *Nicking the tail* is a cruel operation, which is now going much out of practice.

Sect. VIII.—Diseases of the Horse.

6705. *The diseases of the horse are numerous*, as the present artificial mode of his life and his complicated structure might lead one to suspect. External diseases and cases of unsoundness are much more easy to understand than those which are internal, which can only be conjectured from symptoms. In general there are two obvious indications of disease—a refusal to work and a refusal to feed. Lameness speaks for itself; but there may be something the matter with his collar or part of his harness. Every good coachman, or person habitually employed about a stable, should acquire some skill in detecting the symptoms of disease, and should know how to treat the most ordinary complaints, or at least till a veterinary surgeon can be procured; but it should be borne in mind that the difficulty of treating a sick horse is not only as great, but in one respect greater than that of treating a human patient, since he cannot, like the latter, describe his sensations.

6706. *Before the veterinary art became a distinct profession*, the ignorant farrier, pretending groom, or shoeing smith, were all that the owners of horses had to consult; and the fate of these animals was commensurate with the wretched treatment they were subjected to. These men, without any scientific education, often committed the greatest blunders, though they frequently performed cures, as is the case with other quacks. But the establishment of schools for the veterinary art has disseminated an improved practice and spread good practitioners through the country; and, now that the diseases of the horse have been the subject of scientific investigation, it would be imprudent not to avail one's self of the advanced state of knowledge. By a subscription of two guineas a year to the Veterinary College at Camden Town, the best veterinary assistance, perhaps, in the world can be procured, or an opinion obtained on a horse's soundness on which reliance may be placed. In many other places, now, skilful veterinary practitioners are to be found; and, where their assistance is to be procured, no servant ought to assume more than his proper degree of responsibility in the management of a sick stable, nor should his master be so imprudent as to trust him in serious cases. But as such desirable assistance is not always within reach, it would be well that the proprietors of horses should acquire as much knowledge on the subject as possible, as a check upon others.

Sect. IX.—Purchase of Horses.

6707. *Nothing requires more caution than the purchase of horses;* and we give the following hints, which are extracted from the excellent volume "On Horses," published by the Society for the Diffusion of Useful Knowledge:

In the purchase of a horse, the buyer usually receives, imbodied in the receipt, what is termed a *warranty.* It should be expressed thus: "Received of A. B. forty pounds for a gray mare, warranted only five years old, free from vice, and quiet to ride or drive." It is important to observe that the age, freedom from vice, and quietness to ride or drive should be mentioned, because warranty as to soundness alone does not include these. Many disputes have arisen as to what ought to be termed sound or unsound. A horse is sound in whom there is no disease, nor any alteration of structure which impairs his natural usefulness, and he is unsound if he labours under any disease, or had any accident that has impaired his natural usefulness by an alteration of the structure of any part of his body. The term unsoundness does not apply to any original defect in the temper of the horse, or any deficiency in the strength and powers of the animal. The principal circumstances which constitute unsoundness, besides the great number of actual diseases, are *broken knees*, which may indicate a stumbler, though not always; for any horse may meet with an accident, and the knee may now be quite well, though it requires great judgment to distinguish in this case. *Contraction* of the foot is sometimes, but not always, unsoundness; for it is occasionally natural, and not a fault. The following defects are considered to indicate unsoundness: *Lameness*, through any cause; *pumiced foot; sand-crack; spavin; splent; thickening of the back sinews of the leg; thrush; ossification of the cartilages of the foot; defects or diseases of the eyes; coughs, roaring, broken wind,* or *any defects of the lungs; quidding,* or imperfect mastication; *crib-biting; biting; kicking; restiffness.*

In order to complete the purchase, there must be a transfer of the animal, or a memorandum of agreement, or the payment of earnest-money; the least sum will suffice for earnest. No verbal promise to buy or sell is binding without one of these; and the moment either of these is effected the legal transfer of property or delivery is made; and whatever may happen to the horse, the seller retains or is entitled to the money. If the purchaser exercises any act of ownership by using the animal without leave of the vender, or by having any operation performed or done to him, or medicines given, he makes him his own. The warranty of a servant is considered to be binding on the master.

A man should have a more perfect knowledge of horses than falls to the lot of most persons, and a perfect knowledge of the vender, too, who ventures to buy a horse without a warranty. Where there is no warranty, and a defect is discovered after purchase, an action may be brought on the ground of fraud; but this is difficult to be maintained, for it is necessary to prove that the dealer knew the defect, and that the purchaser was deceived by his false representation. If the defect was evident, the purchaser has no remedy—he should have taken more care; but if a warranty was given, it extends to all unsoundness, palpable or concealed. Although a person should ignorantly or carelessly buy a blind horse, warranted sound, he may return it—the warranty is his guard, and prevents him from so closely examining the horse as he otherwise would have done; but if he buys a blind horse, thinking him to be sound, and without a warranty, he has no remedy. The law supposes every one to exercise common circumspection and common sense. If the horse should be afterward discovered to have been unsound *at the time of sale* when the warranty was given, the buyer may return it and recover the price; but this proof is requisite; coughing on the following morning will not be sufficient, except the horse was heard to cough previous to the purchase, for the horse might have caught cold by change of stable. Although not legally compelled to give notice to the seller of the discovered unsoundness, it will be better for it to be done. The animal should then be tendered at the house or stables of the vender. Should the latter refuse to receive him, he may be sent to a livery-stable; for, in case of action, the expenses will be recovered with the price; and it will be prudent for the buyer to refrain from any medical treatment. If a person buys a horse warranted sound, and discovering no defect in him, and relying on the warranty, resells him, and the unsoundness is discovered by the second purchaser, and the horse returned to the first purchaser, or an action commenced against him, he has his claim on the first seller, and may demand of him not only the price of the horse, or the difference in value, but every expense that may have been incurred. When an action is brought, the lawsuit is usually very intricate; a fair trial of the horse is allowed, and a certain time specified; but it is not always easy to ascertain whether the fault lies with the horse or his rider, and sometimes the dealer, as well as the buyer, is hardly used. If the horse is detained after the specified time of trial, he is supposed to be sold, and with all his faults.

In London, and in most great towns, there are repositories for the periodical sale of horses by auction. They are of great convenience to the seller, who can at once get rid of a horse with which he wishes to part without waiting month after month before he obtains a purchaser, and who is relieved from the fear of having the horse returned on account of breach of the warranty, because in these places only two days are allowed for the trial, and, if the horse is not returned within that period, he cannot be returned afterward. They are also convenient to the purchaser, who can thus in a large town soon find a horse that will suit him, and by which, from this restriction as to the returning the animal, he may, perhaps, obtain 20 or 30 per cent. below the dealer's prices. But although an auction may seem to offer a fair open competition, there is no place at which it is more necessary for a person not much accustomed to horses to take with him an experienced friend, heedless of the observations or manœuvres of the by-standers, the exaggerated commendations of some horses, and the thousand faults found with others. There are also always numerous groups of low dealers, copers and chanters, whose business it is to delude and deceive.

The principal repositories in London are, Tattersall's, at Hyde Park Corner, for racers, hunters, and superior horses; Young's, at the Bazar in King-street, Portman Square, for horses of every description; Dixon's, in Barbican, for machiners and good hackneys; and Morris's, in St. Martin's Lane, for draught horses and hackneys. Horses should be sent two days before the sale.

Sect. X.—Faults of Horses.

6708. *Horses, notwithstanding their many excellent qualities, are likewise subject, more or less, to defects and disagreeable habits, termed vices.* Of these, *restiffness* is one the most dangerous, and is generally the consequence of bad temper or bad training. It appears in the form of kicking, rearing, plunging, or bolting, and but rarely admits of a cure. A good and determined rider may, for a time, conquer a horse, but he generally returns to his old tricks the first opportunity; and the best thing that can be done with a very restiff horse, in most cases, is to turn him over to some other work. *Biting* is a fault that is not easily corrected, and which requires certain precautions to guard against. *Kicking* is another fault for which there is rarely any cure, particularly if not taken in time; it is very bad in the stable, but kicking in harness is much worse. *Irritability* in cleaning is most generally the consequence of a tender skin and bad management. *Viciousness to shoe* is likewise usually owing to want of skill in managing, but should be corrected, since owing to it lameness is often occasioned, and not by any fault of the smith. *Crib-biting* is a troublesome fault, and difficult to prevent; the horse will not only bite and destroy his wooden manger, but, if it is lined with iron, he will bite it and injure his teeth, as well as disperse and lose his corn. The best remedy appears to be muzzle sufficient to enable him to pick up his food, but not to allow him to lay hold of the manger. *Some horses will not readily lie down at night*, and stand still till their legs swell; sometimes a fresh, well-made bed, and casting him loose, will tempt him. *Pawing* is a bad habit which some horses have in the stable, by which they destroy their litter, and also the floor; shackles are the best remedy. *Rolling* in the stable is another bad habit, which must be prevented by not allowing him sufficient length of collar-rein. *Shying* is a vice which may be cured by a good horseman, except it be owing to a defect of sight. *Slipping the collar* in the night is a trick that some horses are very clever at; by this they sometimes get at food and gorge themselves, or do some mischief. *Tripping* is a dangerous fault, sometimes owing to lameness; a known stumbler is never safe to ride.

SECT. XI.—CRITERIA OF THE QUALITIES OF HORSES.

6709. *The criteria of the qualities of horses* are derived from inspection and trial. To judges their outward appearance affords a pretty just indication of their powers, and a moderate trial usually enables the same judgment to decide on the disposition to exercise such powers. The qualities indicated by colour have been already noticed. The strength may be judged of by the general form. The spirit, vigour, or mettle, as it is termed, are best ascertained by trial. A horse of vigour and true courage is highly valued, and shows his mettle only when it is required of him. He walks securely and deliberately, and moves with readiness as well alone as in company. Without requiring the whip, he will go from the walk to the gallop, and as easily from the gallop to the walk again, champing the bit and trotting glibly. He is attentive and cheerful; loves to be caressed even when on his journey. He is easily managed, good-tempered, and quiet under difficulties. A hot, fiery horse is as objectionable as one of true courage is desirable; he is known by his disinclination to stand still, and by his mettle being raised by the slightest exercise, especially when in company. Such horses are not safe; they are impetuous, difficult to manage, and are easily frightened.

6710. *A hackney should be well formed behind* to give him strength; and to propel him forward, it is even of more consequence that he be well formed before. In this kind of horse the hind parts are, in some measure, subordinate to the fore, as safety, or freedom from stumbling, is preferable to speed. The head in the hackney should be small, and well placed on a neck of due length and substance to make an "appui" for the bridle, and that proper resistance to the hand so pleasant to the feel, and so necessary for ease and safety. The shoulders should be oblique, and well furnished with muscle, but not heavy; and the withers, in particular, should be high, for the comfort of the rider. The elbows should be turned rather out than in; and the legs should stand out straight, and by no means fall under the horse, or it betokens a stumbler. The pasterns should be neither too oblique, which bespeaks weakness, nor too straight, which wears the horse out, and is unpleasant to the rider. The carcass should be round, or the horse will be weak; the loins straight, wide, and ribbed home; the thighs of good substance; and although the being cat-hammed, or having the hocks turned inward, is defective in beauty, it often bespeaks a good trotter.

Many who consider themselves as judges are in error respecting the *action* of the road horse. They say, "Let him lift his legs well, and he will never come down." But in proportion as he lifts his legs well will be the force with which he puts them down again, the jar and concussion to the rider, and the battering and wear and tear of his feet. A horse with great "knee action" will not always be speedy; he will, indeed, seldom be pleasant to ride, and not safer than others. It is a rule, confirmed by experience, that the safety of a horse depends more on the manner in which he puts his feet down than on that in which he lifts them up; more on the foot being placed at once flat on the ground, or, perhaps, the heel coming first in contact with it, than on the highest and most splendid action. When the toe first touches the ground, it may be easily supposed that the horse will occasionally topple over. An unexpected obstacle will throw the centre of gravity forward, and down he will come. If the toe dig into the ground before the foot is firmly placed, very little will occasion a trip and a fall. To detect a stumbler, look at the shoes to discover where is the wear. If the shoes have suffered a week's or a fortnight's riding without being unusually worn at the toe, and it is perceived that the horse puts his feet flat on the ground, the probability is that he is safe, although his action may not be the loftiest. A hackney for a gentleman should be in fine condition, and his coat should be kept up fine by good grooming, food, and exercise, and not by heat, clothes, and cordials.

6711. *Quick draught horses*, or those for the coach, chariot, post-chaise, and other travelling carriages, must have forms suited to the several purposes for which they are intended, as requiring either strength or speed in the greatest proportion. To make them safe, the fore-hand should rise, the back should be straight, the step should be short but quick, which fatigues least. As they approach the hunter in form, they are best fitted for quick work, and as they resemble the best kind of agricultural horses, which are large, they are calculated for heavy draughts, as coaches, &c. But in all a portion of blood gives courage, durability, and condenses strength with less bulk, by which activity is gained. It is of great consequence to a coach horse that the neck and head be so formed as to be enabled to remain well to the bridle.

Sect. XII.—Condition of Horses.

6712. *The term condition of a horse*, though conventionally well understood among horsemen, is not easily defined, nor rendered distinctly intelligible to others. It might be supposed merely to imply those appearances that denote ordinary good health; but though it includes this, it has likewise a peculiar technical signification. It means such a condition or state as is most favourable towards performing the particular kind of work to which he is to be applied; this condition in the cart-horse implies a healthy state, with a general fulness and lustiness of body and muscles necessary to his drawing heavy weights. In the racer and hunter, on the contrary, these qualities are not what are required to be in condition, but such a state of body as fits them for accelerated and long-continued motion, dependant upon great condensation of muscular fibre with the smallest bulk, which is promoted by the absorption of all fatty matter, favourable to the lightness and free action of the lungs. The horse-dealer who has, by means of warmth, grooming, and change of diet, produced a shining coat and general good health, may produce a horse apparently in as "high a condition," yet upon trial he may be found defective in those qualities that would be "in condition for the field or road."

6713. *A horse is said to be out of condition* when his health is deranged, or is, in other respects, not fit for his peculiar work, and he is to be brought into condition by veterinary skill, or by a certain training to be given by the experienced groom. To effect this with race-horses or hunters is an affair of great delicacy, requiring much practical knowledge, but to bring and keep carriage and saddle horses in condition is more within the experience of an ordinary groom. To promote this object effectually, it is useful to possess as much knowledge as can be acquired respecting the physiology of the animal in general, the nature of various kinds of food, and the science of nutrition, the best construction of stables, and the effect of exercise, cleanliness, dressing, and good management generally; in short, of every circumstance that may affect his improvement or deterioration. Nor are theoretical and scientific views to be despised, because, although they cannot stand instead of experience, they may confirm or correct the notions of those who have to depend upon practice alone, which, although often the right result of experiment, is sometimes mere empiricism; and it is to the addition of true science to the art of managing horses that many modern improvements are owing.

Sect. XIII.—Precautions in Travelling.

6714. *Before setting out on a journey on horseback*, it is proper that the horse is in good condition, and to see that all the appointments are in proper order. The bridle should not be new, but one that the horse is accustomed to. It should be a double-curbed one. The snaffle can be ridden with certainty; but the snaffle cannot do the work of the curb in staying a horse, in saving him from the ground under stumbling or fatigue, or throwing him on his haunches, or tightening his mouth. It is of still more consequence that the saddle be one that the horse has worn before, and that fits him thoroughly. The girths should be made of the best materials, to prevent accidents; and if the saddle be liable to come forward, however objectionable the appearance, a crupper had better be used. Some days before a journey is attempted, if the shoes are not in order, shoe the horse; but by no means let it be done as you set off, otherwise, having proceeded on your journey a few miles, you find that one foot is pricked, and lameness ensues; or, if this be not the case, one or more shoes pinch, or do not settle to the feet, all of which cannot be so well altered as by your own smith.

6715. *It is always best to begin a journey by short stages*, which accustoms the horse to continued exertion. The distance a horse can perform with ease depends greatly upon circumstances. Light-carcassed horses, very young ones, and such as are low in flesh, require often baiting, particularly in hot weather; horses in full condition, and such as are from seven to ten or twelve years old, are better when ridden a stage of fifteen or twenty miles, with a proportionate length of baiting time afterward, than when baited often with short stoppages. The state of the weather should also be considered; when it is very hot, the stages should be shorter. As fatigue weakens the stomach, it is best to ride the horse gently the last two or three miles. If a handful of grass can be got by the roadside, it will wonderfully refresh the horse without delaying much. In hot weather let the horse have a gulp or two of water in passing a clean pond, but not more. A little cold water, even when the horse is hot, is very refreshing to him, and may be given with safety, although a large quantity at that time would be dangerous. None should be given him till a few minutes after he is pulled up, and has recovered his wind; nor should he have much while he is getting cool. Cold water is apt to produce colic or cramp in the bowels, for which the best preventive is to keep in exercise by a quick or a gentle trot. Should cramp in the bowels take place, the best remedy is four ounces of sweet spirit of nitre, given in a pint of warm milk, with about a tea-spoonful of ground ginger, mustard, or pepper. On going up a hill, walk the horse, and walk yourself if possible, which relieves him, and take care that no stones get into his feet. On bringing the horse into an inn after a journey, after the saddle is taken off let the perspiration be removed with a sweat knife, and then, with a rug thrown over him, let him be walked till he is cool. When dry, let him be put into the stable, and have some good fresh hay, which may be sprinkled with water; if very thirsty, he may have a little water: he is then to be dressed, rubbed, foot-picked, and foot-washed, by sponging, but not by riding into the water; proceed then to feed him with corn and beans. It is to be observed that a horse's digestion does not begin after a bait in less than an hour, and continues three; if the baits are at too short intervals, they fail of their object. If a horse seems disposed to lie down after fatigue, encourage it. At night foot-stopping is useful, and litter, with plenty of water with his food. If very much fatigued, perhaps a mash will be necessary. Some recommend that before a horse sets out on a long journey, he should be a little accustomed to irregularity in feeding. If a shoe should get loose on the road, proceed cautiously to the nearest smith. A fast pace will throw the shoe and break the foot. Should the shoe be hanging off, or twisted across the foot, pull it away entirely, and remove any loose nails that might run into the foot. A sandal has been invented to put on the horse's foot in case of such an accident: it is fastened on by straps and buckles.

Sect. XIV.—Riding.

6716. *The art of riding* is best taught in schools for the purpose; but a recapitulation of the principal points to be attended to may not be useless.

The best form of saddle for general riding is one in which the cantle is not so high as the military, nor so low as the racing saddle. The pommel should be no more raised than is necessary to keep the whole completely free from the withers. The stirrups should be substantial, not only to prevent breaking, but also that by their weight they may fall to the foot when accidentally slipped away, which is of more consequence than at first sight may appear. If they are of the spring kind, it is also desirable; but it is still more so, that the spring leather should be used, which prevents the danger arising from horses catching the leather in the projections of doors, gates, &c.

6717. *To mount properly,* stand rather before the stirrup than behind it; then with your left hand take the bridle short, and the mane together; help yourself into the stirrup with your right, so that, in mounting, your toe does not touch the horse. Your foot being in the stirrup, raise yourself, till you face the side of the horse, and look directly across the saddle; then with your right hand lay hold of the hinder part of the saddle, and, with your left, lift yourself into it. When mounted, let your position in the saddle be square, and the purchase of your bridle such as not to pull your shoulders; and let your body have such an even posture as if you held a rein in each hand. In holding the bridle, grasp the reins with your hand, which should be held perpendicularly, with the reins passed, the lower within the hand, and the upper between the fore and next fingers. The reins are then brought over the fore-finger, and firmly held by the thumb. It is often directed to place the little finger between the lower reins; the practice of this may be optional with the rider, and in a very fine hand is desirable. The bridle should be held at such a length as to enable you, if your horse stumbles, to raise his head, and support it with your arms, and by throwing your body backward at the same time, you frequently may save a horse that would otherwise fall.

6718. *A graceful and proper seat* on horseback is greatly dependant on a right disposition of the legs and thighs, which should hang down nearly straight, easily, and without force or constraint, all which is brought about from above, by placing the body flat and evenly on the saddle, and opening the knees, whereby the fork will come lower on the saddle. The thighs should be applied to the saddle and to the sides of the horse by their inner surfaces, so as to bring in the knees and toes; and although the line may be properly broken by some little irregularities, yet the foot, the knee, the hip, and the shoulder should deviate but little from a perpendicular line. The ball of the foot should rest within the stirrup, and should be even with the heel, or very slightly elevated above it. Avoid any stiffness in the legs, thighs, or body; all should be lax, but in a state able to embrace the horse, either for support or as aids to him. The loins, particularly, should be lax and pliable, as a coachman's on a box, and for the same reasons; for, by sitting thus loosely, the rough motions of both are broken. To depend upon the embrace of the knees for support is to lose the benefit of a true *equipoise* of the body, and is rather to stick on a horse than to sit on one.

6719. *When you are troubled with a horse that is vicious,* which stops short, or by rising or kicking endeavours to throw you off, you must not bend your body forward, as is commonly practised in such cases; because that motion throws the breech backward, and moves you from your fork, or twists and casts you out of your seat; but the right way to keep your seat, or to recover it when lost, is to advance the lower part of your body, and to bend back your shoulders and upper part. The rising of the horse does not affect the rider's seat; he is chiefly to guard against the lash of the animal's hind legs, which is best done by inclining the body backward. But the usual method of fixing the knees in all cases of danger only serves, in great shocks, to assist the violence of the fall. To save yourself from being hurt in these cases, you must yield a little to the horse's motion; by which means you will recover your seat if displaced, or keep it at such times as would dismount a less skilful horseman.

6720. *If your horse grows unruly,* take the reins separately, one in each hand, put your arms forward, and hold him short, but do not pull hard with your arms low; for, by lowering his head, he has the liberty to throw out his heels; but if you raise his head as high as you can, this will prevent him from rising behind. Is it not reasonable to imagine, that if a horse is forced towards a carriage which he has started at, he will think he is obliged to attack or run against it? Can it be imagined that the rider's spurring him on, with his face directly to it, he should understand as a sign to pass it? These rational queries are submitted to the serious consideration of such as are fond of always obliging their horses to touch those objects at which they are or affect to be frightened. Indifferent horsemen, Lawrence observes, should never venture on horseback without spurs. Those who reflect upon the predicament of being placed between a deep ditch and a carriage at which their horse shies, will see the necessity of this precaution.

6721. *Previously to mounting,* every one will find his account in examining the state of both horse and furniture with his own eyes and hands; for however good and careful his groom may generally be, it is a maxim that too much ought not to be expected from the head of him who labours with his hands. Besides, all such sedulously avoid trouble, particularly in nice matters. For example, see that your curb is right; that your reins are not twisted; that your girths, over the other, still bear exactly alike; but, above all, that your saddle lies exactly level upon the horse's back.

6722. *On getting off the horse,* hold the bridle and mane in the same manner as when you mounted; hold the pommel of the saddle with your right hand; to raise yourself, bring your right leg over the horse's back, let your right hand hold the hind part of the saddle, and stand a moment on your stirrup, just as when you mounted. But beware that, in dismounting, you bend not your right knee, lest the horse should be touched by the spur.

Mules and Asses.

6723. *Mules* are a breed between the horse and the ass; but the race is incapable of reproduction. Mules are highly esteemed in the south of Europe as beasts of burden, but in this country they are only occasionally used for draught. They are more hardy in constitution, more muscular in proportion to their weight, and more patient than horses. They are also less subject to disease, and longer lived, being commonly able to work during full thirty, or even forty years. They are fed at less expense, and when in the hands of humane masters, it is said that their character for restiffness is unjust. They answer well for hard and rough roads, being very sure-footed. They have been long introduced into Ireland, but in England there is a prejudice against rearing them. In Spain, where great attention is paid to the breed of mules, they are used to draw carriages and for riding, and there is a royal stud of asses for breeding them at Reynosa in the Asturias. It is thought by some persons that their employment might be usefully extended in this country.

6724. *The domestic ass* is comparatively of recent adoption in Europe. It appears that they were scarce in England in the time of Queen Elizabeth. Little or no attention has been paid to the common and inferior breed here. They are several others of different qualities, as the Arabian race, chiefly used for the saddle; and a fine sort is reared in the Isle of Gozo in the Mediterranean, &c. Asses are little employed, except by the poorest people ,and are then chiefly supported by the pickings of lanes and by-ways, and yet they carry heavy loads, and might be rendered very useful in many ways. Their employment for riding and drawing small vehicles is well known.

BOOK XXV.

DAIRY, AND THE MANAGEMENT OF DOMESTIC ANIMALS.

CHAPTER I.

THE MANAGEMENT OF COWS.

6725. It can scarcely be necessary to point out the advantages to many private families in the country of keeping a few cows, particularly where the distance from a town is considerable, and the facilities for obtaining milk few. Besides the gratification of having cream unadulterated, butter churned fresh for breakfast, syllabubs, and other preparations, the possession of a supply of the most nutritious food for the younger members of a family is of great value.

In the following observations we propose confining ourselves to directions for keeping cows for the domestic dairy, and for making butter and cheese; but we do not intend to go into all the details necessary for a dairy farm, where the manufacture of those articles is carried on with a view to profit.

6726. *Cows may always be purchased* at the markets and fairs in the vicinity of large towns, the price varying from £7 to £20.

Certain characters or marks of a good cow have been given by writers on cattle; such as wide horns, a thin head and neck, large dewlaps, full breast, broad back, large, deep belly, the udder capacious, but not too fleshy, the milk-veins prominent, and the bag tending far behind, teats long and large, buttocks broad and fleshy, tail long and pliable, legs proportioned to the size of the carcass, and the joints short, &c. But these descriptive indications will be of little or no use to a person inexperienced in the purchase of cows; and, as much imposition is frequently practised in markets, it would be advisable to have the selection made through the medium of a person skilled in this matter, in whom confidence can be placed. Some recommend, as the most certain way of knowing how long a cow may be presumed to continue in milk, to purchase one which has a calf a fortnight old; the calf may be disposed of immediately, as the feeding it up to a state fit for the butcher will scarcely compensate for the loss of the milk.

6727. *It is of importance to select cows of a proper breed*, as there is a great difference in their qualities as to affording quantity as well as richness of milk; some are also of a quiet and docile temper, and others more or less wild and unmanageable. It is observed, as a general rule, that the cows of the short-horned or hornless breed afford milk of the best quality, while they are less dangerous to the milkers than the long horned. The cows that afford the greatest quantity of milk are the large breeds of Lancashire, Yorkshire, and Staffordshire; but they require much food, and would starve on land where a smaller kind, as the Scotch or Welch cows, would find an ample supply. The Suffolk duns and the Ayrshire cows, both small breeds, unite in a useful degree quantity and quality of milk; and the Devonshire and Welch thrive under ordinary keep, and stand the winter season well. But the Alderney cow is superior to every other for the richness of its milk and butter, though the quantity is small; it will yield only two gallons of milk a day, while the Suffolk dun will give more than double that quantity. The Alderney is small and gentle, but looks always poor; they are now dear, and are found only in private establishments.

Where the best milk is the only or principal object in a private family, the Alderney breed is preferable; but where butter is a great consideration, those breeds are to be chosen which are known to afford good milk and cream in the largest quantity.

6728. *The various modes of feeding cows are technically divided* into *grazing*, or feeding on grass in the fields; *soiling*, or giving them green food cut and taken into the house; and *stall-feeding*, which is confined chiefly to hay, together with succulent roots, either in a raw state or steamed.

6729. *Of these the most perfect is certainly grazing on pasture land*, where the cows can range at liberty amid abundant pasturage; but this, if many cows are kept, requires fields of considerable magnitude, and that suitable land can be had contiguous to the mansion. Although much has been said respecting the good qualities of certain roots and artificial grasses, yet experience has shown that no food is comparable to that of good natural pasture for milch cows; for not only does it yield a greater quantity of milk, but the flavour of grass butter may always be distinguished, by its superior richness and delicacy, from that which has been made from milk produced by feeding in the house; its quality, however, may be injuriously affected by the recent application of manure to the land. Cows, though quiet in their stalls during the winter, yet evince a strong degree of restless anxiety to be at liberty when the spring season advances; and when pasture land is abundant, they should be turned out during the day as early as possible in the spring, and brought in at night to be fed upon sound meadow hay, until the weather becomes warm, and the grass affords a full bite. Some even allow them to lie out during the whole night, from the month of May until about the end of October; but then they ought to have a shed to take shelter in, and to shield themselves from the heat of the sun in the middle of the day. It is the custom in Scotland, and many parts of Ireland, to tether the cattle upon the grass lands, which is rendered necessary, in general, by the want of enclosures. This, in some instances, is better than suffering them to wander over the ground, as only part of the grass is eaten up at a time, while the rest has time to grow. Whether a professed dairy servant be absolutely necessary will depend upon the number of cows and the nature of the establishment, and whether butter and cheese are to be made, &c.

6730. *In cases where grazing land cannot be procured*, and yet the advantage of keeping a cow or two may be desired, this may be effected, in many situations, by keeping them in doors in a cow-house; although it cannot be expected that they will thrive quite so well, nor yield such milk, as when they have the opportunity of collecting their food in the open fields. It is well known, however, that in many parts of the Continent, particularly in Switzerland and the whole of Flanders, as well as in the vicinity of London, cows are kept in this manner all the year. There are, indeed, many advocates for this mode of feeding cattle, called *stall-feeding*, as preferable on the score of economy. It is argued that cattle injure the grass by treading, staling, dunging, and lying down upon it; and also that many grasses go to seed, and are wasted from not being cut in time; whereas the manure being collected in the stable can be employed more advantageously, and that the cattle are not so much annoyed in the house by flies, and do not injure the fences. It is likewise shown that the same quantity of land cultivated for stall-feeding will support a great many more cattle than as pasture land. Stall-feeding is much practised in Sussex, and Lord Egremont used to have his milch cows tied up during the greater part of the year; he maintained that one third of the food was saved, that the cows were fed with a fourth part of the usual trouble, that more dung was made, and that there was no spoiling the ground.

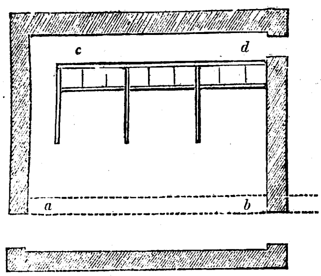
6731. A small piece of land, even perhaps little more than half an acre, may be made to produce grass sufficient, when cut and brought into the house, to keep a cow nearly the whole year; whereas it would be quite impossible for her to derive her whole food from the same quantity of land were she suffered to tread over it. Indeed, it would not be judicious management even to suffer the cows to range over the grass after the hay had been taken from it, on account of the injury it would occasion by treading; it would be much better to close the field at this time, and allow it to revive with the aid of a little manure and fresh grass seeds. Notwithstanding these facts, this practice is not much followed in England, though enough has been done to show its practicability if found desirable. The trouble attending it appears to be a considerable objection.

Construction of the Cow-house.

6732. Horned cattle are much hardier than horses, and much less liable to disease; they will endure a greater degree of cold in winter, and of heat in summer, and they require less delicacy of management in their lodging. No horse could be kept in his stall for months without exercise in the open air and yet retain his health; but milch cows are kept in the neighbourhood of London standing in the same stall for a year or two with scarcely ever being taken out; and in Germany, from the severity of the climate, and the poorness of the pastures in many places, the cows are stall-fed the greater part of the year. It does not follow from this, however, that cows are not benefited by being frequently in the open air. In many parts of England, from the usual mildness of the winters, the cows, instead of being tied up, are allowed to run at large in a yard which has a cow-house attached to it for them to shelter in; and when this is the management, the construction of the cow-house is usually little attended to. Indeed, in many parts of this island, the cow-house is kept in a dirty condition; and we would do well to take a lesson from our neighbours in Holland, and in some parts of France, where the cow-houses, even of the common farmers, are kept in a very superior degree of cleanliness, and are well lighted and ventilated. In some of our large establishments for supplying milk, and in those of many wealthy individuals, great improvements have been made in this part of domestic economy, the leading principles of which we propose here to state.

6733. *On common farms, cows are not usually kept in separate stalls* in the cow-house, except in cases of sickness, or when they are near calving; but although it requires a little more room, separate stalls are preferable; the divisions need not be long nor high. The floor of the stalls, or of the standing room, ought to be perfectly level, since it has been found that a slope is apt to occasion abortion. One of the principal differences between the house for horned cattle and those for horses consists in the gutter *a, b, fig*

Fig. 898.



898, owing to the more fluid nature of the dung of the former, which makes it necessary to have a passage, *c d*, for serving them with food between the manger and the wall. This gutter for the dung should be about eight or nine feet from the manger, and generally one foot broad, and three or four inches deep; it is better to be flat than curved at the bottom, because, in the latter case, the cattle are apt to slip in crossing it. The dung is cleaned out every day by a scraper, and there should be a space of three feet between the gutter and the wall. In some establishments the bottom of this gutter has been laid with oak planks bored full of holes, or cast iron grates, to allow the fluid dung to pass into a drain beneath; and if a broom be now and then passed over this bottom, together with some small supply of water at one end of the gutter, the cow-house may be perfectly sweet and clean; or, if the aperture into the drain do not extend the whole way, there might be gratings at certain places, or round openings with covers. The dung may be passed into the manure tank.

6734. The manger is a trough of boards, stone, or iron; and it should be so placed that the upper edge may be from a foot to eighteen inches from the ground, or about the height of the cow's knees; and it may be eighteen inches broad, and a foot deep. In order that it may hold the various kinds of food conveniently, it may be divided into three parts; one for dry food, another for moist food, and the third for water. Some have also a kind of rack for hay or grass.

6735. Litter in the stalls is not universally used; but it is better for the cows to have straw to lie down upon than the bare paving, or even boards. The cows are fastened by a halter or chain, passing through a ring in front of the manger, and loaded. Cow-houses in England are generally kept almost quite dark; but this is unfavourable to *cleanliness*, the want of which is detected by light. When windows are used, they should be provided with outside shutters luffer boarded, to keep off the intensity of light, and yet allow of ventilation, too much light being found to disturb the repose of cattle, and to encourage flies. Some space should be appropriated for the store of dry food. In Holland and the Netherlands, and likewise in some of the first dairies in France and Germany, cows are combed and brushed like horses; and this is beginning to be practised in gentlemen's dairies in England.

6736. In general, cleanliness is not only agreeable to the sight, but it is very beneficial to the health of all animals; on this account it is best to have the inside of a cow-house whitewashed, if not plastered. Ventilation should be provided for, which is best done in the roof, or it may be managed by tubes in the walls, in the same manner as was recommened in stables for horses, should there be any rooms over the cow-house. It is not only necessary that a cow-house should be comfortably warm and very airy, but more especially that it should be dry; for although a certain degree of warmth is healthful, yet cows, if kept dry, are not very susceptible of cold; and fresh air should never be excluded.

6737. *The calf-house* should be separate from the cow-house, placed so near as not to be inconvenient in carrying the milk, and yet not so placed that the cow cannot hear or see the calf, as that would disquiet her, and prevent her feeding. The calf-house may be fitted up like the cow-house, only on a reduced scale. Great cleanliness is particularly important.

6738. *A feeding-shed* for cattle is a useful appendage, where the cows can be in the open air occasionally, or while the cow-house is cleaning: it may have a rack or manger for food. *A room for steaming food* for cattle, and for washing potatoes and other roots, is likewise found convenient.

6739. *The sorts of food to be given to cows* that are kept in houses, with little or no access to fields, must depend, in a great degree, upon what is to be procured in the locality; but it may be well to point out the usual kinds. Cut grasses, natural or artificial, such as lucern, clover, and vetches, being generally plentiful in the neighbourhood of large towns, are frequently sold in bundles, and should be given, if possible, fresh cut, and before they have had time to wither. Hay has been sufficiently described when treating of horses, and forms great part of the food of cows, particularly in the winter: it should be of the best quality. Straw is likewise used, of which oat-straw is the best.

Fresh grains from breweries, public or private, can generally be procured in all towns, and are much used in some places, as in milk establishments; but though they occasion a great flow of milk, it is of a poor kind. The grains should, if possible, be fetched three times a week, that the cows may have them perfectly sweet, for they will refuse this food as soon as it acquires an ill taste. In the neighbourhood of London, where the cow-keepers make great use of grain, it is the practice to put it into pits, in which they tread it down and cover it close, by which it will keep fresh for a month or two. It may likewise be packed very close in casks, which should have holes in the bottom to drain off the moisture; for this purpose sugar casks, which may be purchased very cheap at the grocers', answer very well.

Those who have gardens of any extent usually have some spare vegetables for the cows, from which the rotten leaves should be carefully separated. Roots of all kinds, as carrots, parsnips, mangel-wurzel, and potatoes, are excellent food for cows. Turnips are likewise much used, but they impart a disagreeable flavour to the milk and butter; the Swedish less than the others. It has been asserted that this unpleasant flavour may be corrected by mixing a small quantity of saltpetre with the milk; but this has scarcely any effect. Linseed, pea, and oat meal, mixed with other food, improves the quality of the milk; and mashes of bran and pollard have the same effect.

6740. *It is not a general practice with us to prepare food for cows by cookery*, yet it is well known that most vegetable substances have their nutritive properties developed and improved by some kind of culinary preparation. Some trials have been made in boiling and steaming roots, and it is thought with advantage. Bran, which contains but little aliment, is improved by steeping it in water, and allowing it to ferment: in Prussia it is the practice to prepare winter food for their cattle, by making cabbages and beets into a kind of sour-crout.

6741. The grasses, when they can be procured, form the best summer feeding in doors, or, as it is termed, *soiling;* and hay and carrots constitute the most salubrious and best fodder for winter. Succulent vegetables of all kinds contribute much nutriment to cows, and increase the quantity of their milk; and milch cows may be maintained through the winter in milking condition by giving them some of these with sound wheat or oat straw, with, or even without, hay.

6742. In beginning cattle with green food in the house, after they have been used to dry, it must be given at first sparingly, lest they should eat more than is proper; thus, tares, lucern, and clover, which cattle relish extremely, would, if eaten too greedily, ferment in the stomach, engendering air and causing disease. If they have more than they can eat, they will blow upon it, and afterward reject it; and it is proper to remove it from them before they are quite satiated. Straw or hay should be given as fodder, to correct the laxative effect of the grasses and raw roots; and, in general, it is proper to vary the food of cattle somewhat, to cause them to relish it.

6743. *To keep cows in the best condition for milk*, they should have hay of the first quality in the winter season, and this in an unlimited degree, that they may always feed till they are perfectly satisfied; and, when the weather permits, they should have access to meadow land, where they may feed on such green vegetables as are present, which will give their milk and butter a greater degree of richness: if they are always kept in doors, and foddered with straw, their milk cannot be expected to be so good. Common salt is much relished by cows, and, when added in moderate quantities to their food, is said to improve their milk, and likewise their general health.

6744. It is very essential that milch cows should be kept always in good condition; as, when they are ever suffered to become very lean, particularly in the winter season, it is impossible that they can be brought to afford a large quantity of milk, except by getting them into perfect condition in the summer months.

6745. *The times for feeding* should be as soon as possible after daylight in the morning, at noon, and a little before sunset, leaving sufficient time for the animals to lie down and ruminate.

6746. *The water given to cows* should be of the purest kind; and, if taken from a cold spring, should be warmed till it is of the temperature of the air in summer. Some recommend stirring a handful of meal in each draught occasionally.

Having described the general principles of feeding and managing cows, it may be proper to state what has been found to be a judicious daily routine in the cow-house.

6747. *The daily business of the cow-house* should commence at five in the morning, by removing the soiled litter, cleaning out the manger, and putting into it the food to be given first, whether grass mixed with a little hay, or any other; the door should now be shut, and the cows left for an hour to eat their meal undisturbed. At six the milking may take place, taking care to follow the directions to be afterward given. After this is finished, the cows may be turned out into the yard, or wherever they can take exercise, and have access to plenty of good water; and in the mean time the cow-house can be cleaned out thoroughly, and the manger scalded. At nine o'clock, when the cows are again put into the house, a mash may be given, consisting of half a bushel of grains to which has been added a sufficient proportion of water at a scalding heat in which has been boiled a quart of barley meal and a pint of malt dust; a table-spoonful of salt may be added, and the whole suffered to cool a little below blood-heat before it is given. At two o'clock the cows may have a second feed of the green food and any other vegetables with water, which may have a little meal stirred in. At four the second milking takes place, and at six a mash, as before. At eight the litter is made up for the night, and the manger and rack, if any, supplied with green food and hay.

The above-mentioned is the usual summer treatment of cows kept wholly in the house; the winter treatment only differs in substituting various roots sliced, raw or steamed, with some hay, for the green food. The roots must be laid up in store in a cellar or some dry place where frost cannot touch them, in sufficient quantity to last for the season.

A moderate-sized cow will consume from 80 lbs. to 100 lbs. of green food per day, and a bushel of roots per day in the winter. She will eat a truss of hay a week in winter, and half as much, if on the grasses, in the summer.

6748. *The cow goes between nine and ten months with young*, and rarely produces more than one calf at a time. She should be dried off at a reasonable distance of time before the expected time of gestation be completed. If she be continued in milk too long, it will injure her health as well as that of her progeny; but this time will depend, in a great measure, upon her keep. In some cases cows are run dry six weeks or a month before calving, while in others, where they are very well kept, they may be continued in milk, without injury, until a fortnight before the time: when dry, they should be suffered to remain quiet, and should be well attended to. The time when they are near calving may be known by what is termed springing at the udder, or a collection of liquid in the bag, which assumes, in some degree, the appearance of milk, and may be drawn from the teats.

6749. *When the time of gestation draws near*, the cow should be placed apart from other cattle for a week or two previous to her calving, and where assistance can be had when needed. Should this be neglected, the progress of the birth should be left as much as possible to nature; but in difficult cases we refer the reader to Mr. Youart's "Account of Cattle." In ordinary cases, he recommends that "a pint of sound warmed ale should be given in an equal quantity of gruel; warm gruel should be frequently administered, or, at least, put within the animal's reach; and access to cold water should be carefully prevented." Parturition having been accomplished, the cow should be left quietly with her calf, which she then licks and cleans. A warm mash and gruel should be put before her, and slightly warmed. Two or three hours after, it will be prudent to give an aperient drink consisting of a pound of Epsom salts and two drachms of ginger; the calf should be suffered to remain with her, otherwise fever and inflammation of the udder may ensue: in case of the teats being sore, they should be fomented with warm water. In general, things go on regularly; but should it be otherwise, a cow-doctor or other skilful person should be called in.

When, from neglect, a calf drops in the yard or field, there is a great hazard of its perishing, and this may considerably endanger the life of the cow. Should this happen, and the mother take cold (which may be known by her shivering and refusing her food), she ought immediately to be driven into a warm place, together with her calf, and fed with sugar sops and ale, and with the best and sweetest hay, and should not be suffered to drink cold water. By this treatment she will most likely recover in a few days; but, should the disease continue, recourse must be had to balls composed of aromatic cordial substances.

CHAPTER II.

MILKING AND MANAGEMENT OF MILK.

6750. *Cows are generally* milked at stated intervals, twice in twenty-fours hours, throughout the year. In some districts they are milked three times; but though by this more milk is obtained, it is of poorer quality. Milking, in some parts of England, is performed by men, but it is most usually the work of women. The milker ought to be mild, good tempered, and cleanly. If the operation is performed harshly, it becomes painful to the cow, which, in this case, brings into action her faculty of retaining her milk; but, if gently performed, it seems rather to give pleasure, as appears from the cows coming to be milked, in some countries, at the call of the milkers. Dr. Anderson observes that many instances have occurred in which cows that would not let down a single drop of milk to one dairy-maid, let it flow in abundance to another. For the same reason, when cows are ticklish, they should be treated with the most soothing gentleness, and never with harshness or severity; and when the udder is hard and painful, it should be tenderly fomented with lukewarm water, and stroked gently, by which simple expedient the cow will be brought into good temper, and will yield her milk without restraint. It is of importance that the whole of the milk in the udder should be thoroughly drawn from the cow when she is milked: that portion of milk which is left seems to be gradually absorbed into the system, and nature generates no more than to supply the want of what has been taken away. If this lessened quantity be not again thoroughly drawn off, it occasions a yet farther diminution of the quantity of milk generated; and so on, from less to less, till none at all is produced. In short, this is the practice followed when it is meant to allow a cow's milk to dry up entirely, without doing her any hurt.

6751. *If the milking be not carefully performed*, not only will the quantity be diminished, but the quality will also be inferior; the first of the milk is the poorest, and gradually becomes richer, until the last drainings of the udder, or what is commonly termed the "afterings."

It has been ascertained by Dr. Anderson that the loss of half a pint of this milk occasions the loss of as much cream as would be afforded by a far greater quantity of the first milking, besides that portion of the cream which gives the greatest richness and flavour to the butter. This he decided by the following experiments: "Having taken several large tea-cups, exactly of the same size and shape, one of these was filled at the beginning of the milking, and the others at regular intervals till the last, which was filled with the dregs or 'afterings.' These were each weighed, the weight of each cup being settled, so as to ascertain that the quantity of milk in each was precisely the same; and from a great number of trials frequently repeated, with many different cows, the result was thus: the quantity of cream obtained from the first drawn cup was, *in every case*, much smaller than from that which was last drawn; and those afforded less or more as they were nearer the beginning or the end. The quantity of cream obtained from the last drawn cup from some cows exceeded that from the first in the proportion of *sixteen* to *one*. In other cases, however, and in particular circumstances, the disproportion was not so great; but in no instance did it fall short of the ratio of *eight to one*. The difference in the quality of the cream, however, obtained from these two cups was much greater than the difference in the quantity. In the first cup the cream was a tough, thin film, thinner, and perhaps whiter than paper; in the last, the cream was of a thick consistence, and of a richness of colour that no other kind of cream was found to possess. The difference in the quality of the milk that remained after the cream was separated was, perhaps, still greater. The milk in the first cup was a thin bluish liquid, like as if a very large portion of water had been mixed with ordinary milk; that in the last cup was of a thick consistence and yellow colour, more resembling cream than milk, both in taste and appearance."

6752. *The average quantity of milk* which is afforded by cows varies according to the breed, pastures, season, and winter keeping. In the principal cheese districts, large cows will give from eight to twelve quarts per day, and some will give nearly twice this quantity for short periods; but when cows give an unusual quantity at one milking, it is remarked that they either go off their milk much sooner, or else their milk has less richness in it than that of others which do not give so large a quantity. Smaller breeds do not give nearly so much; perhaps from two, three, six, eight.

6753. It is better to milk them abroad in fine weather than to drive them home from any considerable distance; and it is advisable to have some home paddock not far from the house, where they can be put under cover while milking; at which time it is expedient to lay before them some favourite food which they can relish with appetite; for they will thus not only remain more quiet, but they will also yield their milk more readily.

6754. *When the milk has been drawn from the cow, it should be carried gently*, and with as little shaking as possible, to the dairy, where it is strained through the sieve. It is then put into the coolers, or shallow pans, which should not exceed three or four inches in depth, and about a gallon and a half or two gallons in capacity, where it is left for the cream to rise to the surface, which it does within a few hours, according to the temperature of the air. Those who are particularly nice, either in the consumption of the raw cream, or in making the very best butter, skim the milk, perhaps within six or eight hours; but when intended for ordinary butter, it is generally left at least twelve hours, and in cold weather twenty-four, or even thirty-six hours, according to the weather, and then it is sometimes skimmed a second time. It is requisite that the milk-pans themselves should be nearly of the temperature of the milk when that is put into them, and therefore, in winter, they should be scalded with hot water, or placed before a fire previously to their receiving the milk, as the cream will rise if this be suddenly chilled.

Milk, which is put into a bucket or other proper vessel, and carried to a considerable distance, so as to be much agitated, and in part cooled before it can be put into the milk-pans to settle for cream, never throws up so much or so rich cream as if the same milk had been put into the milk-pans directly after it was milked.

6755. *In separating the cream from the milk*, first run an ivory or silver bladed knife closely round the sides of the pan, to which the cream adheres firmly, and draw it to one side; lift it off with the skimming dish, which is generally pierced with small holes, an act which requires some dexterity, both to avoid leaving any creaming behind and to prevent any portion of the milk being mixed with it. The cream is put into the cream-bowl to be carried to the cream-barrel. In large dairies, the milk coolers have sometimes an aperture in the bottom, stopped by a peg, which is taken out when the cream has completely risen, allowing the milk to pass through, leaving the cream at the bottom, and this is then drawn up in the same manner.

With respect to the thick milk from which the cream is taken, or *lappered milk*, as it is called in some parts of the country, it is usually employed in England for feeding pigs, though in Scotland and Wales it is thought no bad food for human beings; and it is, without doubt, *particularly wholesome*

CHAPTER III.

CONSTRUCTION OF THE DAIRY-HOUSE.

6756. Where one cow only is kept, a separate dairy-house can scarcely be necessary, or it may be on a very small scale; but where several cows are kept, and butter or cheese is to be made, this becomes essential, and we proceed to point out the principles on which it ought to be constructed.

6757. *The spot where it should be placed* must depend much on convenience and the nature of the locality, but it should not be too far from the house, nor too near the cow-yard.

6758. *The temperature of the dairy* should be as equal as possible at all times of the year; that is to say, as cool as possible in summer, and sufficiently warm in winter. The building should be so placed, if possible, as to be defended from the sun's rays, which may be sometimes effected by trees; and the construction of the building should be such as to prevent, as much as possible, the changes in the temperature of the external atmosphere from affecting that of the interior.

6759. *The walls* may be of any convenient material. Some have been made of brick, built double, or hollow in the interior; and such walls are, upon the whole, the best for preventing the passage of heat through them; but this construction may be limited to the chamber appropriated to keeping the milk.

6760. *The roof* has most usually been made of very thick thatch, either of straw, reeds, or fern, these being bad conductors of heat; a tiled roof is either too hot in summer or too cold in winter; but thatch is subject to early decay, besides harbouring vermin. Large, strong slates are to be preferred, as being more impervious to the weather, and more durable, and they require few rafters. A lath and plaster ceiling below the slates, either plain or covered, will be necessary for warmth.

6761. *The floors* of ordinary dairies are usually paved with brick or tiles; but neither of these can be recommended; for they are never so level, nor the joints so close, but that the spilled milk will lodge there, creating an unpleasant odour. Brick and tile also absorb much wet, and, being long in drying, cause a chill in winter that gives rise to dampness and mouldiness; large, smooth slabs of paving-stone are much better. Lately, slate has been satisfactorily introduced for this purpose; it is sawed into plates three feet square and half an inch thick, at 5*d.* per foot superficial, 7½*d.* per ¾ thick, and 10*d.* for 1 inch thick, by North and Co., at the London Docks. The slates are laid in a bed of mortar, or, what is better, having a layer of concrete four inches thick under the mortar. This slate has been found to be even stronger than stone. The floor should have a fall to a trap drain in the corner. It appears from experiments of the Bishop of Llandaff, that slate absorbs only $\frac{1}{200}$th part of its weight, whereas tile absorbs $\frac{1}{7}$th; and the slate, when exposed to a temperature of 60°, was dry in a quarter of an hour, while the tile had not lost all its moisture in six days. For an ornamented dairy, tiles to imitate mosaic may be employed.

6762. *The sides of the interior* should be plastered or stuccoed; but if they are lined for three feet above the shelves with glazed Dutch or white tiles, it will have an agreeable effect.

6763. *The windows* should be double, but made to open, with lattices covered with wire gauze, to prevent the entry of flies, and with double shutters of wood, to guard more perfectly against severe cold in winter.

6764. *The shelves* may be of flag-stone, marble, wood covered with lead, or slate. The latter appears to be the best material. The proper thickness for slate shelves is one inch, which costs 1*s.* 2*d.* per foot superficial, without fixing, and if polished, 1*s.* 6*d.* per foot. The brackets to support them may also be of slate four inches deep and two inches thick, fixed edgeways, with one end let into the wall; or they may be of iron. A large table in the centre will be found useful.

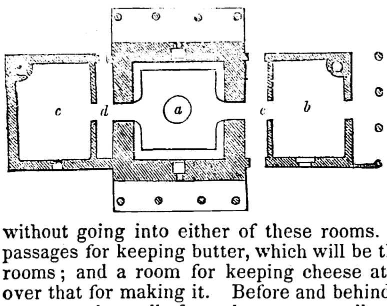
6765. *Ventilation* will be best obtained by means of an aperture in the roof, through which a funnel may be carried from the milk-room, having a regulator.

6766. *A complete dairy* should consist of several apartments, depending upon whether butter only, or both butter and cheese, are to be made. It should have an apartment to keep the milk in while it is throwing up the cream, a room to serve as a dairy-scullery, and a third for churning: cheese may be made, perhaps, in the last; but if there is much of it, or if more convenience be desirable, a fourth room may be devoted to cheese-making.

6767. *Abundance of good water is essential to a dairy:* if a well can be had adjoining, it will be very desirable; if not, there should be a cistern conveniently placed, and well supplied; likewise proper drains should be made for carrying off the water.

6768. *A dairy for a private family* may be constructed according to the plan, *fig.* 899.

Fig. 899.



a is a milk-room; *b* the dairy-scullery with a copper fixed in the corner, and a pump communicating with a well, or having a cistern for water; the outer door opens into a covered place to hold the vessels that are drying. *c* is the room for churning butter, and also for making cheese, having its copper, cheese-press, various vessels, shelves, &c. These two rooms are separated by passages from the milk-room, *d*, *e*, which is thus kept more cool and quiet, the entrance being into one of the passages without going into either of these rooms. Space may be found in the ends of these passages for keeping butter, which will be then accessible without going into any of the rooms; and a room for keeping cheese at a distance from theb utter may be placed over that for making it. Before and behind the milk-room may be verandas effectually to screen the walls from the sun, as well as for ornament. The plan is the only thing necessary to be given here, for the elevation may be of various designs, according to the taste of the architect or builder. Nor will it be necessary to give plans for a dairy on a smaller scale, or a more extensive one, which may require the talents of an architectural designer. It is sufficient if we point out the principles upon which they should be constructed.

6769. *A dairy-room is sometimes an elegantly ornamented apartment*, and much taste has been employed in fitting them up, with a fountain playing up in the centre, which has the effect of keeping the air cool. A thermometer should be kept in the room, and the temperature should range from 48° to 55°; if it falls too low, the heat should be raised by some artificial means. When there is much milk, its warmth, as just drawn from the cows, will raise the temperature a little. It has been suggested by Mr. Young that there should be a trough passing through the wall of the dairy of sufficient dimensions to admit of pouring the milk from the pails with safety, having a hair sieve so placed as that the whole of the milk may pass through it before being conveyed to the cooling-pans, as by this simple contrivance the necessity of boys or others with dirty shoes entering the dairy-house is prevented.

6770. *The utensils of the dairy* are pails for milking into; sieves of hair cloth for passing the milk through to free it from hairs or other impurities, sometimes silver wire cloth is used for this purpose; milk-dishes, or coolers for holding the milk while it is throwing up its cream; a cream-knife of ivory for separating, and dishes of marble, or of tin, for removing the cream, with holes in the bottom to let the milk run off; bowls or barrels for holding it; churns for making butter; scales, butter-prints, and boards for weighing, measuring, and ornamenting it; tubs for hot and cold water for washing the various vessels, and a portable rack for drying them on in the open air.

6771. *Milk coolers* are the shallow vessels to put the milk in after it is drawn from the cow, that the cream may be thrown up. They are generally made of wood, and maple-tree is preferred, from its lightness and cleanliness of appearance; the best milk-pails are made of the same. The only objection to wood is the great trouble that is required to keep it perfectly clean, and it wears rough. Metals have been tried, as lead and zinc; but these, the former in particular, being poisonous when dissolved, as they are apt to be when the milk becomes acid, should be banished from the dairy. It has been said that zinc will cause the milk to throw up more cream; but this is an error. Tin plate is safe, but rusts except it be kept very dry; and cast iron, tinned inside, is heavy, though durable. The brittleness of earthen-ware in general is an objection; and common ware being covered with a glaze in which lead forms an ingredient, is thought to be improper, since the milk, when it becomes acid, may act upon the lead in the glaze. Earthenware coolers, glazed with salt, were such made, would be free from this objection, as also would be porcelain; but the latter is far too expensive for common use. Slate is sometimes formed into coolers, and answers very well, except that the cement at the angles is apt to give way sometimes.

6772. *The most perfect cleanliness is essential* in every operation of the dairy. All the vessels in which milk is put, as well as the cheese, must be scalded, scrubbed, rinsed, and dried every time they are used. If any vessel is neglected, and tainted with soured milk, it acts as a lemon upon milk put into it, and this is sometimes difficult to remove, and perhaps may require boiling with a little potash or soda, and washing very well afterward in hot water, that none of the alkali may remain to give a disagreeable taste. Some recommend soap instead of alkali, as it leaves no taste behind. Dairy-maids should be extremely clean in their persons and dress, and should never enter the milk-room with a dirty apron covered with hairs from the cow-house.

6773. *The management of a dairy should be conducted with the greatest regularity*, and every operation should be performed at the proper time. It has been observed that hastening or delaying any of these will cause butter or cheese to be of an inferior quality, even from milk that, under other circumstances, would have produced the best.

CHAPTER IV.

THE MAKING OF BUTTER.

6774. The chemical principles of milk and butter, as well as the varieties of each, have been explained in Book VII., Chap. IV., and to that we refer the reader; we propose now to give the details of the usual method of making butter.

6775. *Butter* is made either from the cream alone or from the milk unskimmed. When quantity rather than quality is desired, the latter method is practised, but the former furnishes the best butter.

6776. *When butter is to be made from the cream alone*, the milk is skimmed two or three times till it will yield no more cream, and the barrel or other deep vessel into which it is put should have a spigot with a piece of close silver wire gauze over the aperture on the inside for drawing off, from time to time, any thin serous part of the milk which may happen to be there, for, if that be suffered to remain, it would act upon the cream, and injure the quality of the butter. It does not appear to have been determined exactly how long the cream should be kept before it is churned, but from three to six days is the usual time, which, however, varies among persons who make good butter, being, in a great measure, regulated by convenience. Many people imagine that no butter is of good quality except what is made from fresh cream; but this is an error, for the formation of butter only takes place after the cream has acquired a certain degree of acidity, and no butter, of even tolerable quality, can be obtained from cream that is not more than one day old. The cream from every milking should, however, be kept apart until it becomes sour, and not be mixed up with sweet cream, at least not until the moment of churning, for the mixture occasions a fermentation, which, though partly prevented by the churning, is liable to dispose the cream to become a little putrid. When, however, the cows have been fed on roots, the sooner the cream is churned the better. The best butter is made from the cream skimmed off the first time, and the second skimming will make an inferior butter.

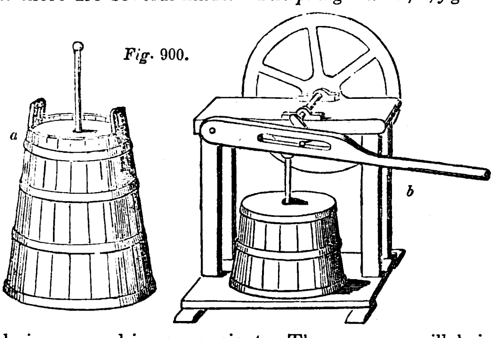
The practice of putting the milk of all the cows into one vessel, there to remain till the whole milking be finished is injudicious, not only on account of the bad effect of agitation and cooling, but because it prevents the distinguishing of the best from the worst cow's milk, and using them separately where it is desirable.

6777. *Particular attention should be paid to the temperature in which the milk is kept while it is throwing up the cream.* It is found by experience that if the heat be too great, the milk is apt to coagulate suddenly, with little separation of the cream, and it becomes sour so rapidly as to injure every operation; while, on the contrary, when the milk is kept in a low temperature, the cream separates in a very slow manner and with difficulty, acquiring a disagreeable bitter taste, the butter being scarcely able to come at all, and, when obtained, is small in quantity and poor in taste. If the cold should ever become too great in the winter season, this may be remedied by artificial means; among the simplest of which is introducing a barrel of hot water closely bunged up, and placing it on the floor of the milk-house, where it cools, giving out its heat very gradually; or hot bricks may be laid down for the same purpose; a chafing-dish with burning embers is objectionable, as the air generated by charcoal is apt to prove injurious to the milk.

6778. *When butter is made from whole milk,* the process, as followed at Glasgow, and described by Mr. Aiton, is as follows: The milk, as drawn from the cow, is placed in the coolers until the cream has risen, and it is emptied, before it has acquired any acidity, into a well-scalded vat of size sufficient to contain the whole of the milking, or, perhaps, of two milkings. The whole must now sour before it is churned; in souring it becomes thick, or, as it is called, lappered, which will require a few days. Care must be taken not to break the curd or lapper of the soured milk before it is put into the churn.

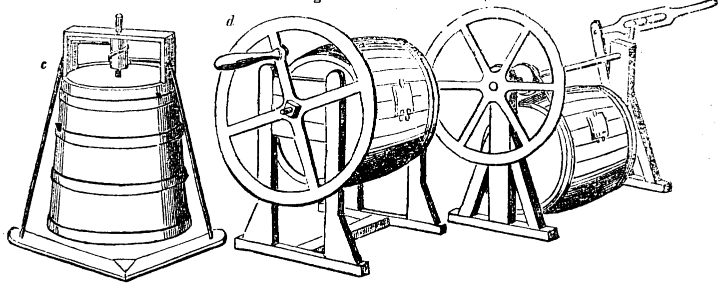
6779. *Of churns* there are several kinds. The *plunge churn, a, fig.* 900, is that which

Fig. 900.



is most commonly in use, and is very ancient. The cream or milk being put in, and the top put on, the churning is performed by means of a long handle passing through a hole in the top, and furnished at the lower end with a perforated circle of wood, which agitates the milk by being moved up and down by the dairy-maid. This method is the most effective for the purpose, but is very laborious in its operation. Mere agitation of milk in a close vessel, a large glass bottle, for instance, continued for a sufficient time, will produce butter, but not of the best quality, if the agitation be not given with a degree of regularity. It requires some skill to churn properly with the common plunge-churn: a few irregular strokes have been known to injure the butter. When once begun, the churning must proceed regularly. The best time for churning in the summer is early in the morning, before the sun gets much power. To obviate the difficulty and fatigue of working this churn, another mode is sometimes employed, as shown in *b, fig.* 900; in this the plunge-staff is moved up and down by a lever worked by hand, and, by means of a crank, motion is given to a fly-wheel. In very large dairies this method is extended by causing the levers to be worked by a horse. In the *Lancashire churn, c, fig.* 901, the barrel is upright, and the axis, with its beaters within, is turned by a cord passing round, the two ends of which are fixed to a pair of levers or treddles worked by the

Fig. 901.



feet of a person standing upon them, the motion being given by alternately pressing first one and then the other.

6780. The *common barrel-churn, d, fig.* 901, is turned round by an axis and winch, to which is attached a fly-wheel, the barrel lying horizontally; on the inside are perforated beaters, and there is a square aperture on the side for having access to put in the milk and take out the butter; this is securely closed by an iron fastening. One advantage of the barrel-churn is, that it requires no skill to work it.

e, fig. 901, is a construction of the barrel-churn by which it can be worked by the action of a lever instead of a winch, a crank connected with the lever giving the rotatory motion. Several other contrivances for churning have been invented, but the above may sufficiently serve as examples. We may observe that an objection to the barrel-churn is the difficulty of cleaning the inside, from the smallness of the aperture.

6781. *The operation of churning,* whether it be cream or whole milk, is performed in the same manner; but the latter, being so much larger in quantity, the process is more laborious, and requires more time. From two to three hours' churning are necessary in making butter from milk, whereas an hour and a half is sufficient with cream. The best temperature for churning butter from cream has been very satisfactorily determined by a number of experiments sanctioned by the Highland Society of Scotland, and published in their Transactions. From these experiments it is concluded that the most proper temperature at which to commence the operation is from 50° to 55°, and that at no time ought it to exceed 65°; while, on the contrary, if at any time the cream should be under 50°, the labour will be much increased without any advantage being obtained, and a temperature of a higher rate than 65° will be injurious as well to the quantity as quality of the butter. But milk and cream, when churned together, require a higher temperature, which, it is generally thought, must be equal to 70° or 75° before butter can be obtained, and the common practice is for one person to pour in a small quantity of warm water gradually while another is churning. A thermometer here, it is evident, would be very useful, but the only one the dairy-maid knows is her fingers, and she is usually correct. It is necessary to observe that all churns should be well washed out and scalded immediately after the butter is taken out, and that butter-milk should never be suffered to remain in them. The churn should be scalded in the inside with hot water before the cream is put in, to prevent the butter from *clinging* to it. Should the butter stick to the churn, which it is apt to do in warm weather, pour in a little cold water to solidify it.

6782. *As soon as the butter is made* it must be separated from the butter-milk, and put into a clean wooden dish, the inside of which should be well rubbed with salt, to prevent the butter from adhering to it. The butter must now be pressed, to get out all the milk that may be lodged in the cavities of the mass. In this operation some persons throw the butter into cold water, or pour water on it, to assist in separating the milk, but this should never be done, as it injures materially the quality of the butter. It should only be well worked with the hand, or, what is much better, with a flat wooden ladle or skimming-dish, having a short handle. A considerable degree of dexterity as well as strength is requisite in effecting completely the extraction of all the moisture, and, in some places, it is the practice to beat the butter with two flat pieces of board, but it must not be too much kneaded, or it will become tough and gluey. A small quantity of salt is usually added, though some prefer it entirely without salt; this is matter of taste.

6783. In the summer season, while the cows are fed on grass, it is not requisite to give butter any factitious colour; but in the winter and spring months it is common with dairy people to alter that tallowy appearance which is natural to butter at these seasons: this is effected by means of a little arnotto, which, after being reduced to as fine a powder as possible, is incorporated with the cream before it is put into the churn. In Devonshire they sometimes make butter from clouted cream, which, they think, gives a superior butter. For the manner of making clouted cream, see Book VII., Chap. IV.

6784. *Butter is made up*, before it is sent into the house or to table, in various forms, sometimes into rolls or cylinders six or eight inches long, and from an inch to two inches in diameter, or into round pats stamped by butter-moulds. When butter is too soft for the latter purpose, it may be put into small wooden vessels, which may be allowed to swim in a tub or cistern of cold water; or, what is better, they may be set in an ice-house for an hour or two, or the water in which the small floats are set may be iced; but on no account should water be allowed to touch the butter in making it up. When formed into the desired shapes, it may be kept in a cool place till wanted.

6785. *The salting and curing of butter* have been already treated of in Book X., Sect. IX., "On the Preservation of Food."

CHAPTER V.

THE MAKING OF CHEESE.

6786. The chemical nature of cheese, and of the coagulation of milk by which it is formed, have been already treated of in Book VII., Chap. IV., Sect. III., to which we refer the reader; and we proceed to the practical directions for making it.

6787. In the preparation of cheese several circumstances must be considered: such as the season of the year; the milking, as well as the cattle furnishing the milk, and their feeding; the method of preparing the rennet and colouring; the mode of breaking the curd; the management of the cheese in the press; and its treatment afterward in the cheese-room. The goodness of cheese depends more or less upon all these, but most of all, perhaps, on the mode of making; for, although it is generally considered necessary, in order to make the best cheese, to use new milk that has not been skimmed, yet some of the best cheese in Europe, as that of Parmesan, is said to be made from skimmed milk. The processes in different parts of England likewise differ somewhat, and hence the various kinds of our cheese; but the general principles and mode of manufacture are nearly as follows, being the mode usually adopted in Cheshire, as described by Holland.

6788. *The utensils requisite for making cheese* are, besides the usual ones for holding the milk, *the cheese-tub*, in which the milk is coagulated and the curd broken; the *cheese-knife*, generally a thin spatula of wood, but sometimes of iron, used for the purpose of cutting or breaking down the curd while in the cheese-tub; *the cheese-tongs*, or *ladder*, being a wooden frame occasionally placed on the cheese-tub, when the vat is set on it in order to drain the whey from the curd; *the vàt*, a strong kind of wooden hoop, turned out of solid elm, with a loose bottom, which, as well as the sides, is perforated with holes to allow the whey to escape while the cheese is pressing; its size must depend upon that of the cheese to be made; *the cheese-cloth*, a piece of thin open linen, in which the cheese is placed in the press; *the cheese-press*, a power obtained by a weight, screw, or lever, used for forcing the whey out of the curd while it is in the vat; *cheese-boards*, circular pieces of wood on which the cheeses are put in the cheese-room.

6789. *The proper season of the year for making cheese* is from the beginning of May till the close of September; or, in favourable seasons, to the beginning of October. Very good cheese, however, may be made in winter, provided the cows are well fed.

Previously to commencing the process of making cheese, besides the milk, two materials must be ready for use—the rennet for coagulating the milk, and the substance for colouring the cheese, if any is to be employed.

6790. *The substance called rennet, generally used for coagulating or turning milk to curds and whey*, is made from the stomach of a calf, preserved by means of salt. To understand its operation, we may observe that it is the nature of the gastric juice secreted in the stomach of all animals to coagulate the milk taken into it, as is well known to those accustomed to children. The prepared stomach of ruminating animals is found best for this purpose, and that of a young calf that has been killed before the digestion is perfected is generally preferred for rennet. This preparation is made in different ways in different districts; but the following method, used in Gloucestershire, according to Mr. Marshall, is one of the best: "Take a calf's bag, maw, or stomach, and, having taken out the curd contained therein, wash it clean, and salt it thoroughly, inside and out, leaving a white coat of salt over every part of it. Put it into an earthen jar, or other vessel, and let it stand three or four days, in which time it will have formed the salt and its own natural juice into a pickle. Take it now out of the jar, hang it up for two or three days, and let the pickle drain from it. Resalt it, plunge it again in a jar; cover it tight down with a paper pierced full of holes by a large pin, and in this state it ought to remain twelve months. It may be used, however, a few days after it has received a second salting; but it will not be so strong as if kept a longer time."

6791. *When wanted for use, the rennet so prepared is soaked in water*, to which some add a little lemon and cloves, or an infusion of sweet-brier and dog-rose, to do away any disagreeable smell, and give an agreeable flavour. The strength of the liquid will of course be increased in proportion to the length of time the bag remains in it, and therefore the quantity to be used for turning the milk cannot be stated in any exact portion, but must be ascertained by practice: on an average, we might say that half a pint of the liquid will be sufficient to turn fifty gallons of milk.

As the account by Mr. Aiton of the mode of preparing the rennet in Ayrshire is considerably different, though successful, we shall describe it also. He observes that, "so far from washing away the curdy matter or chyle found in the stomach of the calf, it is carefully preserved; for this chyle is formed by a mixture of the gastric juice of the calf with its food, and, the gastric juice being the coagulating power, the rennet will be stronger for retaining it: indeed, pains are taken, before the calf is killed, to have as much as possible by giving it milk. Accordingly, in preparing the bag or maw, as soon as it is taken from the carcass of the calf, its contents are examined, and any straws or indigested food that may happen to be there are thrown away, but no part of the chyle is suffered to be lost. Two handfuls of salt, at least, are put into the bag and upon its outside; after which it is rolled up in salt, and hung near a fire till it is well dried; and it is understood that it is improved by hanging a year. When rennet is wanted for making cheese, the bag with its contents is cut small, and put into a jar with a handful or two of salt; and a quantity either of soft water that has been boiled, and cooled to 65°, or of new whey taken off the curd, is put upon the bag in the jar. The quantity of water used must vary according to the kind of calf; if that has been newly dropped and not fed, three English pints will be enough; but if it has been fed four or five weeks, a couple of quarts may be put upon the bag to mash, the older calf furnishing most gastric juice. After the infusion has remained in the jar from two to three days the liquid is drawn off, and an English pint more of water or whey put upon the bag in the jar; and that, after standing in a mash one or two days, is also drawn off, and, with the first infusion, strained; the whole is then put up in bottles for use as rennet, and the bag is thrown away and not used for the milk. The liquid may be employed immediately, and will keep for many months. A table-spoonful of rennet so prepared will be sufficient for thirty gallons of milk; but its great superiority over the English is, that it will coagulate the milk in five or ten minutes, whereas the latter requires from one to three hours to form the curd. No harsh taste is communicated to the cheese, if sufficient care be taken in preparing rennet in this way."

6792. *In a case of emergency,* it is said that a decoction of the yellow flowers of the herb called "cheese rennet," or "yellow lady's bed-straw," which blossoms in July and August, will answer instead of rennet. The stomachs of lambs and pigs will likewise coagulate, but not nearly so well as those of the calf.

6793. *In Holland, instead of rennet,* they use a small quantity of muriatic acid for turning milk; and it is said that it is the use of this that gives to Dutch cheese its peculiar pungent flavour.

6794. *Colouring cheese* is, with us, a very general custom. Cheese properly manufactured from good milk, and at the proper season of the year, is always of a yellow cast; and hence the idea of excellence is attached to what is of that colour; and, when made for sale, it is always more or less coloured by artificial means. Turmeric, marigolds, and other materials were formerly used for this purpose; but these have given way to Spanish arnotto, which is a preparation from the red pulp that covers the seeds of an American tree, the arnotto-tree (*Bixa orellana,* Linn.). This pulp is mixed in hot water, and, when allowed to subside, it is made into balls and dried. The usual manner of applying the arnotto is to dip a piece of the requisite weight in a bowl of milk, and rub it on a smooth stone until the milk assumes a deep red colour. This infusion, without the sediment, which is separated by standing a little, is to be added to the milk of which cheese is intended to be made, in such quantity as will impart to the milk a bright orange colour, which will become the deeper in proportion to the age of the cheese. The addition of the arnotto in no way affects the taste or smell.

6795. *The milk intended for making cheese* should be carefully passed through the sieve placed on the ladder over the cheese-tub; and, for the very best cheese, that produced at a single milking is preferable: when it is brought in warm from the cow it is easily turned by the rennet: if the warm milk of one milking be mixed with that of an earlier one, the whole will take longer time to turn.

6796. *The degree of heat of the milk most favourable for coagulation by rennet* is from 85° to 90°, the natural heat at which it is drawn from the cow: if it is below 85°, the milk must be brought to that degree by some means. Some warm it over the fire, which is liable to burn or smoke it; others immerse the lower part of a vessel containing a portion of it into the copper of hot water, and mix this with the rest until the required temperature is obtained; and another method is to add some boiling water to the milk, to bring it to the required temperature, which is said to accelerate the coagulation. If the milk be not warm enough when the rennet is put into it, the curd will be tender, the cheese will never be firm, and will bulge out at the sides; and if too hot, it will cause the cheese to swell, or "heave," and become spongy, hard, dry, and tasteless, because much of the richness has gone off with the whey.

In hot weather the milk in the cows' udders is liable to become very much agitated and heated by their running about; and if rennet be put to it in that state, the curd, instead of coming in one or two hours, will require three, four, or five hours, and will be so spongy, tough, and imperfect, as to be scarcely capable of being confined in the press or vat; and, when released from the press, it will heave or split, and be good for little. Whenever, therefore, the cows are discovered to be in this state, which occurs not unfrequently, during hot weather, where cows are pastured in unsheltered grounds, or where water is not within their reach, it will be advisable to add some cold spring water to the milk as soon as it is brought into the dairy, until it arrives at the proper degree of heat.

6797. *To effect the coagulation of the milk, or, as it is called, to set the curd,* the milk now in the tub has the proper quantity of rennet and colouring added to it. The proportions of these can only be regulated by experience and practice. If there is too little rennet, the milk will not turn; if too much, the cheese will be apt to heave, as well as be rank and strong; and the same effect will be produced if the rennet has been made with bad or foul materials. A handful or two of salt, added previously to mixing the rennet, will promote the coagulation. The proper quantity can only be regulated by practice. After all the materials are put into the tub, the whole is well stirred together; a wooden cover is put on the tub, and over that a woollen cloth is thrown; during the process the milk ought not to loose more than five or seven degrees of its original heat. The usual time of curdling is from an hour to two hours, during which time it is to be frequently examined. If the dairy-woman supposes the milk to have been accidentally put in cooler than was intended, or that its coolness is the cause of its not curdling, hot water or hot milk may be poured into it, or hot water in a brass pan may be partially immerged in it to raise the temperature. This must, however, be done before the coagulation commences, for the forming of the curd must not be tampered with. If it has been set together too hot, the opposite means may be resorted to; but the more general practice is to suffer the process to proceed, hot as it is, until the first quantity of whey is taken off, a part of which, being set too cool, is then returned into the tub to cool the curd. Within an hour and a half, as already mentioned, if all goes on well, the coagulation will be formed—a point which is determined by gently pressing the surface with the back of the hand, in which test experience is the only guide.

6798. *When the curd is sufficiently firm,* the usual practice is to cut it across with a knife through to the bottom, making the incisions an inch apart, and again crossways and round the sides, slowly and gently in the same manner, for the purpose of causing the whey to rise through, that the curd may sink to the bottom with more ease. After a short time, having taken some of the whey out, the cutting is repeated until the curd is reduced to very small pieces. This operation may require half or three quarters of an hour. The cheese-tub is then covered with a cloth, and is allowed to remain for about a quarter or half an hour for the curd to subside; but, previously, some break the curd as small as possible by the hand.

6799. *To separate the curd from the whey,* part of the latter is taken off with a skimmer; the bottom of the tub is now set a little a-tilt, the curd is collected to the upper side of it, and a board is introduced of a semicircular form, and fitting loosely one half of the tub's bottom. This board is placed on the curd, and a 60 lb. weight upon it to press out the whey, which, draining to the lower side of the tilted tub, is ladled out. This operation of placing the curd under the weighted board is repeated several times, until the whole of the whey is drawn off, and the mass of curd is then turned upside down to undergo the same pressure. The board and weight being removed, the curd is then to be cut into pieces again, and pressed both by the weight and by hand as long as any whey appears to remain. Great attention is required in conducting this part of the business. If the whey is of a slightly greenish colour, it is a proof that the curd has been properly formed; but if it be white, it is equally certain that the coagulation has been imperfect, and that the cheese will be of a poor flavour, and that much caseous substance has been lost in the whey.

6800. *The next process is to transfer the curd to the cheese-vat.* For this purpose, the curd is divided into two or three portions, according to its size, and one is put into a pan and broken extremely fine; and some mix a handful of salt, more or less, with it: this portion is then put into the cheese-vat placed to receive it, on a cheese-ladder over the cheese-tub, a coarse cloth having been first placed over the vat; the other portions of curd are treated in the same manner, and added to the last: this breaking may occupy, perhaps, half an hour if the cheese is large. The curd, in its broken state, is now heaped up above the vat in a somewhat conical or roundish form; and, to prevent it from crumbling down, two or three women turn the corners of the cheese-cloth over it, and gently press the curd together with their hands, until it adheres so much that a board can be placed over it, with a part of the cloth between it and the curd. The whole is then put under a 60 lb. weight, or into a press; and, at the same time, if the cheese is large, it is the practice in Cheshire, but nowhere else, to stick skewers into the cone and into the middle of the curd, through holes in the sides of the vat, to facilitate the escape of the whey when they are drawn out. These skewers are frequently shifted to fresh places; and this operation of breaking, pressing, and skewering is repeated if thought necessary, the operation generally lasting about two or three hours.

6801. *The newly-formed cheese is next taken out of the vat,* and put into a vessel of warm or hot whey for an hour, to harden its skin. On taking it out of the whey, and when it has become cool, it is wiped with a clean, dry, fine cloth, and again put into the vat. As the upper surface of the cheese is still above the edge of the vat, this upper part is bound round with a cheese-fillet, or has a hoop put round it over the cloth that covers the whole of the cheese, to preserve its shape, and the cheese is again submitted to the press for twelve or fourteen hours, when it is well skewered as before: if the press stands near the wall, one half only can be skewered at a time; but this occasions no inconvenience, as the skewers must be frequently shifted, there being numerous holes in the sides of the vat. After remaining in the press for half an hour, the cheese is taken out and turned in the vat with another cheese-cloth; and in this manner it continues in the press for forty-eight hours, being turned several times, and the skewers having been lain aside for the last twelve hours. The process just described is for large cheeses; if the cheese is small or thin, it will not require so much pressing and skewering; but, in cheese-making, the perfect extraction of the whey is a very important part of the process, for, if any is left, it occasions rankness and speedy decay.

6802. *The cheese-press* is of various constructions, but should be so contrived that its force be proportioned to the size of the cheese. Its power may act as a screw, a lever, or a dead weight: the last is the most common, as being the simplest. *a, fig.* 902, rep

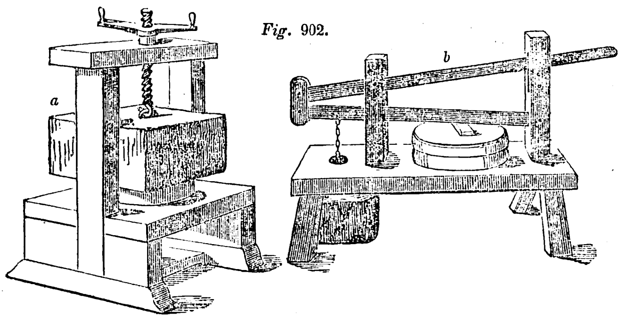


Fig. 902.

resents a cheese-press acting by a weight, consisting of a block of stone raised by a screw, and fixed between uprights that cause it to press level, which is essential to proper pressure. Instead of a single stone, some have a box raised in the same way, but filled with loose stones, which has this advantage, that the weight may be varied at pleasure. *b, fig.* 902, is another press in which the weight is raised by means of a compound lever. Some use a heavy stone, raised and lowered by a tackle.

6803. *The next process is salting the cheese.* For this purpose, in Gloucestershire and Cheshire, it is taken out of the press, and placed nearly mid-deep in the salting-tub for three days, its upper surface being covered all over with salt; or, instead of this, some rub the sides and edges of the cheese with finely-powdered salt. The salting is thus performed after the cheese is made; but in Scotland and some other places the salt is minutely mixed with the curd previous to its being put into the vat. Both practices appear to be equally successful; but the latter is least troublesome, and occasions less waste of salt. Although we have mentioned three days for salting, this must depend upon the size of the cheese, and the time must be varied by experience. Too much salt is unpleasant, and with too little the cheese will not keep. The cheeses, after being salted, are returned to the vats without the cloths, and are again pressed. They are then to be well wiped, and dried for about a week.

6804. *The cheese, being at last completed, is now to be placed in the cheese-room.* This may be a loft, and should be airy and dry: it should be fitted up with proper shelves for the cheese; or, if on a small scale, a cheese-rack may be suspended to receive them, made to lower by a rope and winch. The cheese should be turned three times a week for some time. If they are liable to a kind of blistering, called heaving, occasioned by a slight fermentation, and the formation of air in the interior, the latter may be discharged by pricking them pretty deep in the blistered places, and removing them for a time into a cooler situation. A preventive is to rub on a powder, sold in the shops under the name of *cheese powder*, composed of nitre and bole armeniac: this is put on before the salting, and sometimes proves serviceable; but, if too much be applied, it gives the cheese an acid taste, and actually increases the evil it was intended to prevent. The cheese-room must be kept of a certain temperature; too great warmth will make the cheeses sweat and lose their oily parts, and too much air, or the rays of the sun, would dry them too fast, and make them crack: a medium temperature and ventilation is best.

6805. *The difference in cheese,* not only of different countries, but of different districts in the same country, is very remarkable, and is not yet well accounted for, nor have sufficiently numerous and accurate experiments been made to determine all the circumstances that are most favourable to its manufacture. It is said that little or no improvement has been made of late in the manufacture of cheese.

6806. *The whey formed in making cheese* is generally employed in England to fatten pigs, and is sometimes conducted by leaden pipes into an underground cistern near the pig-styes, where it is raised by a pump when wanted. In some places, however, they first set it by to throw up a sort of cream, from which they make whey butter, which is much inferior to milk butter. Others put the whey on a smart fire, and, when near boiling, mix it with a quantity of butter-milk, and these *flectings*, or *flit milk*, as it is called, form curds, which are skimmed off so long as they arise, and are used as agreeable food.

CHAPTER VI.

POULTRY.

6807. *The term poultry includes* the common fowl, the turkey, goose, duck, guinea-fowl, and tame pheasant. Each of these requires peculiar treatment, which we must describe separately. In Book VII., Chap. V., "On Food," we mentioned the peculiarities of these different birds, and to this we refer the reader; what remains to be treated of is the manner of rearing them.

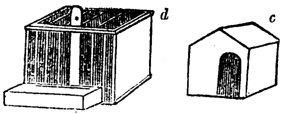
6808. *In some places, a poultry-house* is built large enough to contain all these animals, and this is often found an agreeable as well as useful addition to a mansion, affording an opportunity of observing their habits. Some poultry-houses have been fitted up on a considerable scale, consisting of various compartments, each species of bird being placed in circumstances suited to its nature and habits; and each compartment, besides, including separate divisions for feeding, roosting, incubation, and rearing. Among the most extensive of these, we may refer to that at Lord Penrhyn's, at Wilmington, in Cheshire, which consists of a handsome building 140 feet in length, built of bricks covered with closely-jointed slate, pointed and sanded. It has an extensive court or yard, with colonnades, pavilions, and a pond, the whole being kept in a state of the most perfect cleanliness; others have been erected at Mr. Wakefield's, near Liverpool, at Mr. England's, Aberdeen, &c. How much of the excellences of these first rate constructions are attainable on a small scale will depend upon the taste of the owner, and other circumstances; but although a small collection may be kept in one place, yet the principle of separating each species should not be lost sight of, and it will be found proper to give them different habitations, according to their several habits.

SECT. I.—COMMON FOWLS.

6809. The variety of this bird most usually kept, and the most useful, upon the whole, is the *barn-door fowl*, or common dunghill cock and hen, which are of the middle size, and very hardy. The *Dorking fowl*, with large bodies, short legs, with five claws on each foot, furnish the largest and finest capons, and also lay the largest eggs. *Game fowls* are remarkably delicate in their flesh, and their eggs, though the smallest, are by many preferred. The *Polish fowl*, of a shining black, with crowns of white feathers, resemble the Dorking in their general qualities. The general method of managing them is nearly the same.

6810. *The hen-house* should be on a very dry soil, as nothing is so injurious to the fowls as damp; the place where they are kept should be properly drained, the house paved with brick, and the yard covered with some sound material, as brick rubbish, with sand and gravel, perhaps with a foundation of concrete. Poultry are often confined in a dark, close, diminutive hovel, which is injurious to their health; on the contrary, they should have an airy, well-ventilated place constructed for them, with a yard for exercise. A few hens, for laying only, are easily kept over an out-house, in a convenient situation. Warmth is very essential to fowls, cold rendering them torpid, retarding and diminishing their laying; but too much heat enfeebles them. White hens are more tender, and require to be kept warmer than the dark coloured. It is desirable that the walls of the poultry-house should, if possible, receive a little heat from a chimney or flue in some part of the dwelling, which in some cases may be effected with a little contrivance; and it is not well that the poultry-house should be too large for the number of fowls, as they rather prefer being a little crowded together, on account of the warmth they receive from each other; but ventilation should not be neglected, as bad air generates disease. The walls are best of brick, and may be built hollow, the better to confine the heat; a window is best to the east, and another to the west, with wired lattices, and shutters to close in very cold weather. Roosting-perches or rails should be placed in convenient situations in the poultry-house; and they should not be round nor smooth, but nearly square, and somewhat rough, of a size suitable to be grasped by the claws of the fowls. It is important that every part of the building should be finished close, without crevices, to prevent the entrance of vermin, and the inside should be frequently whitewashed with hot lime; it is necessary to observe that the utmost cleanliness is requisite in a poultry-house. The litter of the nests and the dung should be frequently removed, for no poultry can thrive where this is neglected; the brick floor should be washed every week.

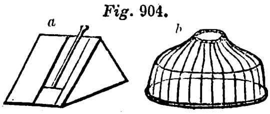
Fig. 903.



6811. *Coops* for fattening, *d, fig.* 903, are likewise requisite, with a trough before for food.

6812. *Nests* are sometimes fixtures, and may be built against the wall, either in one tier or several, according to the number of fowls and the size of the house. When there is more than one tier, each of those above the ground must have a projecting shelf at the bottom for the fowls to reach the nests by, and a slanting board leading to it, with slips of wood nailed on. Moveable nests, *c, fig.* 903, are also occasionally useful. These nests should be well cleaned out with hot lime water after every hatching, to destroy the fleas which infest poultry, and which are not only annoying to them, but also to visiters. It is sometimes necessary to separate some fowls from the rest; such as those which are diseased, which are liable to be ill treated by the rest, as also strangers, and fowls of particular breeds. Coops and cages are useful for this purpose, which may be made in various ways, as *a* and *b, fig.* 904.

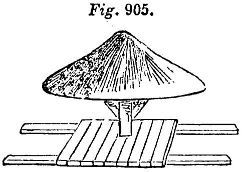
Fig. 904.



6813. *Pens* also may be provided, made of lattice-work, each for a cock and four or five hens to be in during the day, to enjoy the fresh air, and yet be protected from bad weather; and these may serve instead of a poultry-yard when but a few fowls are kept.

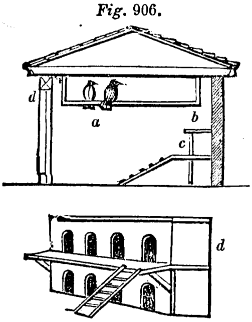
Places for shelter, in case of rain, are necessary to be provided, and *fig.* 905 represents a portable shelter, which can be placed where it is most convenient. In short, it is of great use to make their abode not only healthy, but agreeable to them, in order that they may remain stationary and quiet, and lay and sit when it is desired; as fowls, if they are dissatisfied with their position, are apt to lay in secret places, where it is not always easy to discover their eggs. Among other conveniences in the poultry-yard, there should be small plots of grass or clover planted here and there, if there is space enough, and a few heaps of gravel, sand, or ashes, for the fowls to roll themselves in and cleanse their feathers from vermin.

Fig. 905.



6814. *Fig.* 906 *is a transverse section, showing the interior arrangement of a poultry-house* on a moderate scale, which is found convenient. A row of laying nests, *c*, arranged along the wall, is shown in perspective at *d*, with a shelf before, and a sloping board to ascend to them; there may be breeding boxes beneath. The perches or roosting places are several bars, *a b*, suspended from the timbers of the roof, and a sloping board may assist the fowls to get up to them. The door, *d*, may be high, for the benefit of ventilation when it is opened, and there should be an aperture in the opposite side, immediately below the ceiling, with a regulator. The door should have an opening, also, at the bottom, for the egress and ingress of the poultry, but only just large enough to admit them. Sometimes the place of roosting is distinct from that where the laying and breeding nests are put.

Fig. 906.



6815. *Poultry eat a great variety of food:* all kinds of grain and seeds, and preparations made from them; also most sorts of vegetables, raw or boiled; and they are fond of a certain quantity of animal food, raw or cooked; insects and worms, grubs and maggots, they search for and devour with avidity, and some persons collect these on purpose for them. Potatoes form some of the most economical food; but it is essential not only that these should be boiled or steamed, but that they are given *warm*, for fowls dislike them if cold. In many houses there are many well-known scraps and refuse that will serve for fowls, such as crumbs of bread, fragments of pies and puddings, and even bits of meat and fish, and vegetables, such as lettuce, endive, cabbage, spinach, turnips, carrots, chickweed, and grass. It is generally necessary to give them some kind of grain, as wheat, barley, oats, rye, buckwheat, and maize, or meal made from them into a paste with water. Rice they are fond of at first, but soon tire of it; and much oats, Mowbray says, is apt to scour. Pease and beans are best boiled, and some recommend boiling barley also; but that does not appear to be necessary.

Fowls do not judge so much by taste and smell as by the eye in distinguishing their food, which, when first swallowed, passes into their crop, and, after being there macerated, goes into the funnel-stomach, and then into the gizzard, in which, being a strong sac of the nature almost of gristle, the food is subjected to a powerful trituration, as in a mill, this appearing to answer the same purpose as the teeth of quadrupeds. To assist this effect fowls pick up and swallow many small pebbles and stones; and it is proper to lay some of them about in the place where they are kept. It is proper, likewise, to scatter some lime rubbish, as this earth is necessary to supply the calcareous matter which forms the shell of their eggs. The water given to them should be of the purest kind, for foul or bad water is sure to cause disease.

6816. *The expense of feeding chickens to a condition fit for the table*, according to a statement in the 6th vol of the "Agricultural Magazine," would appear to be very inconsiderable, independently of the trouble and attention required. It is there stated that three pounds of meal of any kind, that will not cost above a penny a pound, made into a paste with water, is sufficient, with such scraps and crumbs as may be easily set aside in a house, to feed and fatten a chicken from the time it bursts its shell till it is fit for the table. It is also said that old fowls, even though fed with food for which money proportionate to the just market value must be paid, will, by their eggs, pay annually at least three times the cost of their subsistence, besides the advantage of the manure which is afforded.

If highly fed from the nest, chickens will be always fit for the table; and pullets which have been hatched in March will lay plentifully through the following autumn and winter, and may be got ready for the table in February, when their laying is finished. High feeding shows itself not only in the size and flesh of the fowls, but in the weight and substantial goodness of their eggs.

6817. *The fattening of poultry*, like that of all other animals, depends upon receiving more nourishing food than ordinarily. In a farm-yard they will thrive upon the common run of the yard, with such offals as may occur from the house or stables. At threshing time they get particularly fat, owing to the plentiful supply of corn, and then they are styled *barn-door fowls*, which are considered by some as the most delicate and high flavoured of all others, both from the full allowance of the best food, and the constant health in which they are kept, by living in a natural state, and having their full enjoyment of air and exercise. The same advantages may be obtained from a good poultry-yard, and feeding them in a similar manner. But there is likewise an artificial mode of fattening that is generally practised, not only by those who bring up poultry for sale, but by others. In this method the poultry not only receive plenty of the most nourishing food, but they are prevented from having their usual exercise, which naturally induces obesity.

In Mr. Wakefield's establishment the poultry were fattened successfully with steamed or roasted potatoes given *warm* three or four times a day; the chickens and pullets, after having been brought to condition in the yard, were confined in dry, well-ventilated coops, and covered in, so as to prevent the entrance of too much light. In this mode of fattening, in general, they are kept in coops so confined that they can scarcely turn themselves, and the food is varied sometimes in different places according to custom. Keeping them in the dark appears to be an important part of the process, but they must likewise be kept clean, and each fowl by itself. Besides potatoes, boiled barley, or meal made into thick gruel with milk or water, or mixed with potatoes, or any of the farinaceous foods which have been mentioned, as pea and bean meal, are particularly fattening. Confinement for ten days or a fortnight in this way will be sufficient for effecting the fattening of chickens. When kept too long, and made too fat, disease ensues.

6818. *Chickens and fowls are fattened for the market usually by the process called cramming*, which is forcing the food down their throats either in pellets or by means of a cramming funnel. For this purpose, in those counties of England most famous for fattening poultry, as Sussex, and Berks, and Essex, various kinds of food have been used, such as ground oats made into gruel, mixed with hog's grease or mutton suet, sugar, hot liquor, and milk; or ground oats, treacle, and suet; also sheeps' pluck, &c.; a mixture of meal made of barley, wheat, millet, maize, and the like, soaked in milk; or oatmeal and water with milk. These are the least objectionable materials; but it is said that poulterers employ likewise animal garbage, which can scarcely produce wholesome flesh. In our Section "On Food," Book VII., Chap. V., Sect. II., where we treated of poultry, some observations by Mr. Mowbray will be found on the probable effects of cramming, which we need not repeat; at the same time, it may be observed that, provided the health of the fowls does not suffer by this mode of feeding, and if only the materials we have mentioned are employed, there may not, perhaps, be much objection to this mode of fattening.

6819. *Capons fatten better than other fowls*, and the operation of making capons is practised by persons who make a trade of it; and is generally best to employ them when they can be had. They are put up in coops to fatten, and are not allowed to go into the yard, as the other poultry would destroy them. They are not subject to moulting.

6820. *One of the principal objects in the keeping of poultry by a private family is to have fresh eggs.* The time for the hens laying eggs depends much upon the warmth in which they are kept, and, therefore, in general, on the season. Cold retards or prevents this, and hence the scarcity of eggs in winter. There are two periods of the year when poultry lay most: these are spring and autumn. The approach of the time for laying is denoted by the hen's cackling, which she does three or four times before she begins; and she then appears very restless, seeking about for a place to lay in, which, after some time, she will choose; but she will require then to be well watched, and means must be employed to induce her to lay in one of the nests prepared for this purpose, for want of which she will be apt to go to some inconvenient place, and it sometimes happens that it is difficult to discover the eggs; but after she has settled herself, she will return again to the same nest. There is a considerable difference in the number of eggs that the different breeds will lay, as well as of the chickens in each breed. Some hens will lay an egg every day; others, one every other day; and others, only one in every three days. The best hens for laying are generally considered to be the dark-coloured, black, brown, or tawny russet; the white are not so good. Pullets, in their first year, if early birds, will probably lay as many eggs as ever after; but the eggs are small; and such young hens are unsteady sitters. The best layers are the Poland breed; the Dorking are likewise good; the latter are remarkable for their tameness and good temper, and possess every good quality required in a small stock. Hens are in their prime at three years old, and after four or five years old they lay unfrequently, and cease altogether on becoming very fat: it is not advantageous to keep them after that period. The eggs should be removed each day as they are laid, as they are liable to be spoiled by the warmth of the hen. They are best kept for a short time in bran, with the large end uppermost: some recommend their being turned every day, but this is useless labour, as the yolk cannot be displaced except the membranes give way or become relaxed by the eggs becoming very stale. For the best methods of preserving eggs for a long time, see "Preservation of Food," Book X., Sect. IX. The chief secret of having new-laid eggs in the winter season is to keep the hens very warm and comfortable, feeding them on cooked food, and to have them young, or, at least, early in moulting, so that the renewal of their feathers may take place in the beginning of winter.

6821. *Moulting.*—Hens, after they begin to lay, continue to do so mostly through the summer, and they cease through the natural process of *moulting*, or casting their feathers, which they do once a year. This is a critical time for all birds; they are usually more or less ill during this time, and poultry are then unfit for the table or for breeding. In moulting, the new feathers grow, forcing out the old ones, and all the nutriment is necessary for the growth of the feathers. The moulting season is later with old fowls than with young ones, and it continues to occur later and later every year as the fowls advance in life; it lasts from one to three months, according to the age and strength of the bird. Young poultry under three years old shed their feathers in the spring; but this period, for full-grown fowls, begins in the autumn. Old hens, therefore, cannot be depended upon for eggs in the winter, such being scarcely full of feathers until Christmas; and these do not begin to lay again until April, producing at last, perhaps, not above twenty or thirty eggs. In general, it is most profitable to dispose of hens while they are yet eatable, or saleable for that purpose, which is the spring of the third year.

6822. *Hatching.*—The females of most birds are disposed to hatch their eggs as soon as they are laid. Hens form an exception, for they may be induced to lay all the summer by removing their eggs before they show any signs of a disposition to sit. This appears at last by a clucking well known to those accustomed to poultry. Hens vary much with respect to their fitness for hatching, and it is remarked that the best layers are generally the worst sitters; it is therefore important, for breeding, to select such hens as are known to be patient and assiduous in sitting on their eggs. It is best, if possible, to select from your own eggs, as most to be depended upon; they ought never to be above three weeks or a month old; they should be nearly of one size, and quite perfect. Some persons are so particular as to mark with ink on the eggs the time they were laid, and it is proper to make an entry in a book of the date when they are set to be hatched. The usual number of eggs placed in the nest is from nine to fifteen, according to the size of the hen. In preparing the nest, short, soft straw should be used, for, if the straw is long, the hen is apt to draw it out with her claws and disturb the eggs. The nest and eggs being ready, the hen should be gently placed upon them and covered with a cloth till she is perfectly quiet. The period of incubation is twenty-one days; and care should be taken that she is not disturbed by any accident, also that the place is warm and quiet: repose and darkness are favourable. The best age of a hen for hatching is from two to five years old. Pullets under two years are too young for that purpose; and the month of February is the best for hatching, though any time from that till October is good; but with proper management a brood may be had at any time of the year. Some recommend that the food should be placed so close to the nest that the hen can feed without leaving it; but it is better, perhaps, to place it at a small distance, as a little exercise is good for the hen. Some will sit so close as to be thought in danger of starving; but that is best left to nature in general. The hens should at this time have plenty of clean water, as they generally drink a great deal. Sometimes they break some of their eggs by accident; when this happens, the broken eggs should be at once removed. The hen instinctively turns her eggs frequently, that every part may receive equal warmth; and this is best left to her management. In some hens the desire of incubation is so powerful that they will sit several times in the year; others will only sit once or twice in the season. Advantage must be taken of the several qualities of being good breeders or layers.

6823. *The young chick*, when hatched, lies in the egg, rolled up like a ball, with its bill under the right wing, and begins generally on the morning of the twenty-second day to break its way out; this it usually does successfully; but it sometimes happens that it cannot extricate itself, and may require assistance, which must be given with much precaution, and does not often succeed. The parental affection of the hen, as Mowbray and Parmentier have remarked, is always intensely increased when she first hears the voice of the chicks through the shells, and the strokes of their little bills against them. The signs of a need of assistance are observed to be the eggs being partly pecked, and the efforts of the chicken discontinued for five or six hours. The shell may then be broken cautiously, and the body of the chicken carefully separated from the viscous fluid which lines it. It is the opinion of Reaumur that no aid ought to be given to any chickens but those which have been near twenty-four hours employed without success.

6824. *The chickens, when hatched,* should, after an hour or two, be removed into a basket lined with wool or soft hay, and kept in a moderate degree of warmth; and, if the weather be cold, near a fire. They require no food for many hours, sometimes even twenty-four. When the whole brood is hatched, the hen is to be placed under a coop, upon a dry spot, with the young chickens. Several different broods should not be within reach of each other, lest they should mix, and the hens maim or destroy those that do not belong to them; nor should they be placed near young fowls, which will be likely to crush them under their feet. The first food should be eggs boiled hard and chopped small, boiled rice, split grits, or oatmeal: watery food, as soaked bread or potatoes, is improper at first. As they gain strength, in a few days, bread soaked in milk, and boiled or roasted potatoes, may be added. Their water should be pure, and often renewed: there are convenient pans made in such forms that the chickens may drink without getting into the water, which often, by wetting their feet and feathers, numbs and injures them. A basin full of water whelmed in the midst of a pan of water will answer the end. Most of the disorders of chickens arise from their getting cold and wet. There is no necessity for cooping the brood more than a few days, but they may be suffered to go out into some small enclosed place for some time before they are trusted in the yard.

In about fifteen or twenty days the hen may conduct them there, and it is highly interesting to see what pride and satisfaction she appears to feel in her young brood, and what solicitude she shows for them. Artificial means may be employed to induce hens to sit when they show no natural disposition; and thus a brood of chickens may be produced at any time of the year. These means depend chiefly upon keeping her on the eggs in a nest or hatching box in a dark, warm place, confining her there by tying her with a string or some gentle means, and giving her a little stimulating food, such as toast steeped in ale.

6825. *It is well known that chickens can be hatched by artificial heat* without a hen. This is practised to a great extent in Egypt, and the method has been imitated on a smaller scale successfully in various parts of Europe; lately by steam, as at an exhibition in London. Although sufficient has been done to prove the perfect practicability of the process, yet it does not appear that in this climate, at least, it could be carried into effect with profit; nor is it, of course, likely to become general, though an extremely interesting experiment. We have already stated the method adopted by Bonnemain in France, which was nearly the same as that employed here lately, only that pipes of hot water were employed by him instead of steam to warm the little chamber in which the eggs were placed.

6826. *The persons whose business it is to look after the poultry* should have been accustomed to live in the country, and should be regular in feeding, keeping them clean, and giving them every other attention; they should be of a mild disposition, should study the habits of the various fowls, strive to please them, and maintain peace among them, as they soon learn to know those who treat them well. The fowls should be carefully watched as to their number, and whether they are gaining or losing condition, what kind of food they relish most, and what agrees best with them. They should be turned out in the morning, according to the weather, and shut up in the evening, at regular times.

6827. *The good health of fowls may be known* by the fresh and florid colour of the comb, and the brightness and dryness of the eyes, the nostrils being free from any discharge, and the gloss of the plumage. The indications of old age are, paleness of the combs and gills, dullness of colour, and a sort of stiffness in the feathers, length and size of talons, and the scales upon the legs becoming large and prominent.

6828. *Fowls are liable to several diseases,* as the pip, roup, fever, rheumatic and inflammatory diseases, besides various others. These have hitherto been little studied, perhaps from the small value of fowls, which offers little inducement to take much pains in their case. It is necessary that those who have the care of them should be acquainted with the most popular remedies, but our limits will not allow us to go into the subject, for which no written directions would avail without experience. Some valuable observations are contained in Mr. Dickson's work "On Poultry."

6829. *With respect to the supply of the market with poultry,* it is remarked that "in most of our farm-houses and cottages in England the poultry are very indifferently accommodated with shelter and food, and large farmers breed only for their own use. On the Continent such quantities are reared, that they are very nearly as cheap as butchers' meat, so that the table of the Londoners are, in a great measure, supplied from France."

SECT. II.—TURKEYS.

6830. Turkeys are more delicate and difficult to rear than common poultry, and preserve something of the wild habits of the original bird in a disposition to wander from home. They have a dislike to be shut up in close places, and the roosting bars in houses appropriated to them should be placed as high as convenient from the ground, being made also much thicker than those for fowls.

6831. *Their food*, in a domesticated state, is the same as that of common poultry, and they consume a great deal; if left at at liberty at a farm-house, they often destroy much of the corn, trampling more under their feet than they eat; they require, therefore, to be kept in some enclosure.

6832. *Turkeys lay* in March; some every day, others every other day. The eggs are fifteen or twenty in number, of a dull cream colour, with reddish speckles. The time of laying is indicated by the vivacity, haughty strut, and peculiar note of the hen, which requires them to be watched, for they are very apt to steal away from home, and lay in some secret place; when this is discovered, the eggs must be brought back, and they must be made to lay in the proper place. To prevent their laying from home, they should be fed by hand in the morning before they go out, and those that are going to lay should be kept back. One turkey cock is sufficient for several hens; where there are more than one, they generally fight.

6833. *The hens begin to sit in April*, and they then cluck like a common fowl. A nest must be prepared of a circular pad of straw, about fifteen inches in diameter, with some bruised straw within. The number of eggs they sit upon is usually eleven or thirteen, and the time of hatching is between twenty-five and thirty days. They are easily made to sit, and are patient sitters. They will also sit anywhere in the house, as in the corner of a back kitchen; but they make inattentive mothers, for they will sometimes straggle a great way over the fields, dragging the young brood after them; and, in consequence, frequently some of the young get left behind, and are lost.

6834. *The young, when just hatched*, are very tender, and require to be kept warm. Some have recommended giving them cordials of various kinds at first, but this is not necessary: the best way is to leave them quiet in the nest to the care of the mother for a day or two, after which they may be put into a basket, or on the ground, as may be found to suit their strength and the weather. When they begin to eat, they should be fed with bread moistened with water or milk. Some recommend a strong paste made of meal of barley, pease, or maize, mixed with chives chopped small, or nettles, or parsley, according to local resources; this is made into balls about the size of a turkey's egg, and held in the hand, or laid in flat cakes on stones, for the young ones to pick at till they are satisfied. Curd, eggs boiled hard, and boiled meat torn in shreds, are likewise given. Meanwhile the hen should be cooped, or put under a kind of cage or crate, such as earthen-ware is packed in, lest she should rob the young of their food. When she is kept in this manner, the young chicks can run about, without wandering too far, and return to her call. They should be fed several times a day, and water should be given as directed for common poultry. They should be accustomed to the open air gradually, at first two hours in the sunshine; and during the first six weeks they should not be allowed to stray from home, but, with the mother, they should be confined to the vicinity of a shed, where they can find shelter in case of rain or cold winds, which are very injurious to them. Or, if they are permitted to cater for themselves in the fields or about the hedges, which they are fond of doing, they should be attended by a boy or girl, who will bring them home again before the dew falls. The mother does not, like common fowls, seek food for them by scratching and other contrivances, nor teach them to do so; therefore the young require more care: some have put a few common fowl's eggs under the turkey with her own, that the chickens hatched from them may set an example to the turkey chicks in looking out for food; others cram the turkey chicks; but this is a bad practice.

6835. *The young, when about two months old, are termed turkey poults*; at that time the membranes on the neck and head shoot out and become of a flesh-red colour; this is called *shooting the red*, and is a critical change in the turkey's life, more so even than moulting. They then require particular care, and to have the best food. After that they may go about into whatever place their mothers are allowed. If there are any woods near, where they are safe, or can be looked after, they are fond of frequenting there, and picking up fallen acorns, beach wart, or wild fruits of any kind, corn in gleaning time, or insects; but a scorching sun, as well as rain, is fatal to turkey poults.

6836. *Turkey poults, which some prefer to the full-grown birds, are fattened for the table* when about six months old, and for this purpose the food which is usually given consists of farinaceous materials, such as soddened barley or wheat, or meal of any grain, boiled with kitchen stuff, or dregs of melted tallow or fat, together with various pot-herbs and potatoes; but their food being much the same as that of common fowls, much oily substances impart a disagreeable flavour to the flesh. Some persons, to save the trouble of breeding turkeys, buy the poults in the market, and fatten them at home by the various scraps left in the house. A fine turkey, when fattened, will weigh fourteen or fifteen pounds when ready for cooking, though it will weigh from twenty to twenty-five pounds when alive. It may be observed, the *turkey cock* is so pugnacious and troublesome a bird, particularly to children, that many object to having one about the house. But though quarrelsome, the turkey is a cowardly bird: they are swift runners, but in their domesticated state are but indifferent flyers: their remarkable antipathy to red is well known, and their strut and pomposity are proverbial.

SECT. III.—GEESE.

6837. *The varieties of the goose are numerous*, but the common domesticated kind is distinguished by the colour, as being white or gray. The one most esteemed is the large Embden white. Geese should not be kept so as to have access to other poultry, being very pugnacious, which harasses the rest. They may be bred on a common, or on marshy ground, as they feed much on grass ; but they should not be suffered to range about the house and grounds, as they are very destructive to gardens and farm crops, preserves, and orchards. Access to water is essential.

Geese and ducks, being nearly of similar habits, may be lodged in the same house, having separate places for laying, sitting, and fattening.

6838. *If kept in the poultry-yard*, they are fed on grain, refuse vegetables, boiled potatoes, warm, or with the meal of oats, pease, beans, or maize, mixed with potatoes, carrots, or turnips. In the harvest, the stubble-field of corn is a proper place to turn them into. They are voracious feeders, and are rather expensive to bring up in a yard only: grass seems to be essential to them.

6839. *Geese begin to lay early in the spring*, generally in March ; and the sign of hens being about to lay is their carrying straws to make a nest with. They require to be watched at this time, lest they should lay in some inconvenient place ; and a nest should be of prepared straw, lined with hair, and made deep ; when once the goose can be induced to lay in it, she will continue to do so. She lays from eight to twelve eggs before she sits ; but if the eggs are removed as soon as laid, a goose may, by plentiful food, be made to lay from twenty to fifty eggs.

6840. *The goose sits thirty days*, and the gander generally remains near her nest, as if for a guard. They should have plenty of food and water near them, that they may not remain long off the nests, and let their eggs get cool. From fifteen to twenty eggs are as many as the goose can cover. The turkey hen is sometimes employed to hatch them ; and sometimes a common hen is made to perform the same office with eight or nine eggs, when it is required not to interrupt the goose from laying.

6841. *When any of the goslings are hatched*, some take them out of the nest, and keep them in a basket with wool until the whole brood has come out, when all should be put under the care of the mother, until they are sufficiently strong to follow her with ease, which they will in a few days. They are fed at first on crumbs of bread soaked in milk, grits, wheat, barley, or oats, coarsely ground, bran, or pollard, and lettuce leaves. The mother may have the same food, but with more corn.

6842. *Geese are fattened* either in their young state, or when they are a month or six weeks old, when they are termed *green geese*, or after they have attained their full growth. The methods for both are nearly the same. They will generally get sufficiently fat if they have the run of the stubble on a farm, but they may likewise be easily made fat by confining them in coops, and feeding well on steamed potatoes, mixed with any kind of bruised or ground grain, pea or bean meal, pollard, milk, &c., made into a paste, giving them, at the same time, plenty of water. The best time for fattening grown geese is in November, or when the cold weather begins ; if put off longer, the pairing season approaches, and prevents their becoming fat. As one of the principles of fattening consists in depriving animals of exercise, this has been carried, on the Continent, to an extravagant length ; and methods have been put into practice which must be branded with the appellation of cruelty ; but, as we do not wish to see these imitated, we avoid describing them.

SECT. IV.—DUCKS.

6843. Ducks being, in a great measure, aquatic birds, will not thrive unless there be a piece of water of some kind for them to swim, or, at least, to dip in, and it is useless without this to attempt keeping them. They ought to have a place separated from ordinary poultry, on account of the great difference in their habits. The wild duck, or mallard, common in many parts of the kingdom, is the original of our domestic breed, of which there are several varieties, though it is not usual to keep more than two or three of these for the table, the rest being only for ornament or curiosity. The tame variety, which is the most common, is the *Rhone duck*, originally from France, which is of larger size than the wild, and high flavoured. The English, or Aylesbury white duck, is milder in flavour, which some prefer, and numbers of them are bred in Buckinghamshire for the London market, on account of their size. The Muscovy duck is not uncommon in a domesticated state, but it is of a different species from the others, and, though it breeds with them, the offspring is a hybrid.

6844. *The best situation for ducks* is where there is a piece of water in pleasure grounds, considerable enough to have a small island, on which may be planted rushes, osiers, and other aquatic plants and shrubs, among which the ducks are fond of rubbing ; and they will breed there, and become so wild that they must be taken by snares or nets. They are likewise reared in abundance about the house, where there is a small pond, and, besides, being easily kept and fattened, have the advantage of being ready for the spit as soon as killed. Although we have stated that a pond or piece of water of some kind is necessary, yet a few ducks may be kept by having merely a shallow tub sunk in a corner of the yard, in which they may dip and wash themselves.

6845. *The food of ducks* is extremely various, and they are, therefore, not difficult to provide for. They will eat all kinds of grain, and every sort of mealy substance, particularly potatoes, as likewise herbage, roots, and fruits, provided they are soft enough. They also devour the offal of animal substances, and are very fond of seeking among the mud of water for worms, insects, and vermin, such as slugs, frogs, &c.; in short, scarcely anything comes amiss to their voracious appetites. As they do not scratch up the soil, they may be sent into the garden, when the dew is on the ground in the morning and evening, to pick up the slugs and snails, which they will do without injuring the borders.

6846. *Ducks begin to lay* in February, or even earlier, and will sometimes lay as many as fifty or more eggs, if these are taken from them before they show a disposition to hatch. They are very apt to lay away from home, and require careful watching; nor are they so easily brought to lay in their proper nests as common fowls. To prevent their wandering, it will be proper to feed them in the laying season in a particular place three or four times a day, observing that the better they are fed the more they will lay, provided they are not made too fat.

6847. *Ducks, when domesticated, are not so well disposed to hatch as hens*, and there is sometimes a little trouble in getting them to sit; when they do, they must have their food placed near, otherwise they are apt to neglect their eggs; and as soon as the young ones are hatched, which is generally in about thirty days, the mother takes them to the water, where they dabble before they have acquired sufficient strength, and often perish, if the weather be cold. On this account, it is a common practice to have ducks' eggs hatched by common fowls, which show more assiduity and patience in sitting. As these mothers have no propensity to go to the water, the young breed gets a little hardy before they are allowed to take to it. But such is their natural instinct, that, although not taught to do so by the nurse, no sooner do they see a piece of water than they plunge into it, to the great alarm of their foster mother, who cannot follow them, and whose warning and anxiety they disregard. This exhibition of natural feeling is so painful to some persons, that they object to have young ducks hatched except by their own species. From eight to ten eggs is the utmost that the ducks can cover. Light-coloured ducks produce white eggs, which are not easily distinguished from those of the hen, but the eggs of dark ducks are of a bluish-green colour. If sitting ducks are given eggs not of their own colour, they will sometimes turn them out of the nest.

6848. *Young ducklings* are hardy, and need not be taken from the mother; it is best to secure both under a coop for eight or ten days, to strengthen them before they take to the water. Their food for the first few days may be bread soaked in milk, and then they may have a paste of meal of any kind, with nettle leaves boiled and chopped. When they have a little more strength, a mash of bran soaked in water, with barley, acorns, or potatoes boiled, together with pot-herbs, may be given, and a little fish may be added to this. From the most tender age, ducklings exhibit great voracity, and eat almost any food that is given to them. They should likewise have a pan of water to dabble in. As one of the natural habits of the duck is to *sift* its food out of water, it is a good mode of feeding young ducklings to throw some oats or other grain into a shallow vessel of water, and to allow them to gather it up, which they appear to take more pleasure in than if it is given to them dry.

6849. *To fatten ducks*, the same principle must be followed as in other poultry; they must be regularly fed with the best food, and kept quiet. As they are greedy, but not nice feeders, various kinds of food are employed; boiled potatoes mixed with oatmeal or bruised oats are found economical and effectual; barley should not be given, as it is said to destroy their flavour. Acorns, when they can be had, are a favourite food with them, and very fattening: malt is likewise highly recommended. When fattened on animal substances, which are very expeditious in accomplishing the business, some are of opinion that the flesh is not so delicate, somewhat resembling that of the wild duck.

Sect. V.—Pigeon-House and Pigeons.

6850. The pigeon-house, or dove-cot, is not so much a favourite appendage to a mansion as formerly, perhaps from the destruction by these birds of the neighbouring crops; but on a small scale, or when they are well fed in the house, this objection may disappear. Some account of the various species of pigeons, and of their qualities as food, will be found in Book VII., Chap. V., to which we refer the reader. We shall here consider the method of breeding them, and their management in the dove-cot.

6851. *The common domestic or house pigeon* runs also into several varieties, commonly called *fancy pigeons*, which are kept for sale by persons who breed them for purposes of amusement only.

Of these, the *carrier* is perhaps the most remarkable. Though removed from their homes to a considerable distance in covered baskets, yet, when let loose, they will find their way back with unerring instinct. This faculty is well known to be employed fo various purposes, as for conveying intelligence in a rapid manner, and even for stock-jobbing purposes. The *pouter* forms another variety, distinguished by its large, distended crop and grotesque attitudes: it is the tamest and most familiar of them all. The *tumbler* has beautiful plumage, and his name is derived from the singular manner in which he tumbles over and over in descending from a great height in the air. Some sorts of fancy pigeons sell for very large sums when very perfect and of rare breeds.

6852. *To stock a pigeon-house*, it is proper to obtain the young birds, called *squeakers*, which are in the best condition in two seasons, May and August; the last is said to be preferable for stock. The common house-pigeon partakes so much of the character of the carrier, that it is difficult to keep old birds in any other place than where they are reared, being known to fly back again and find their way home, even when removed with every precaution; and it becomes necessary, therefore, to procure the young before they have acquired any attachment for locality. The male pigeon is distinguished from the female by his superior size, and he attaches himself to one female only, being proverbial for constancy.

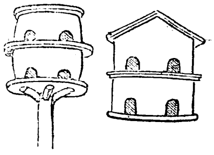
6853. *The pigeon lays two eggs*, which, when hatched, produce a bird of each sex. Having laid one egg, she rests a day before she lays the other, and then proceeds to sit. The period of incubation is about fifteen or twenty days, and the male and female sit alternately, the former in the day, while the female is seeking refreshment abroad: both are equally industrious in procuring food for their young. When the young ones are hatched they require only warmth for the first three days, and the mother during that time never leaves them. Pigeons produce two or three broods in a year.

6854. *Their manner of feeding their young is remarkable.* The old ones swallow their food, consisting of pease and various seeds, and fill their crops, which are the largest in proportion of any birds, and after the food has remained there until it is macerated or softened, and half digested into a sort of pulp, they have the power of forcing it up at will and ejecting it into the opened bills of the young ones, whom they generally feed in this manner three times a day. They continue this mode of feeding for a week or ten days, and then they gradually add food of a harder kind. While so fed by the old ones the young are called *squabs*, which are most in demand for pies; in the next month they are able to shift for themselves, and until they are six months old they are termed squeakers.

6855. *Pigeons live almost entirely on grain and pulse*, but will sometimes likewise eat aromatic vegetables; their power of digestion is very great, and they consume a large quantity of food. To procure it, they fly over a considerable space of ground, and are very destructive to crops at seed time; it is therefore hard upon farmers that persons should be allowed to keep many pigeons without having land of their own. If left at liberty, they will procure food for themselves; but if confined, they must be fed. The best way is to feed them well in the dove-cot, both to keep them at home and prevent their doing injury to the crops. If well fed, they will afford young for the table every month in the year. It is recommended, where there is danger of their destroying crops, to take all the young of the spring brood, or feed them in the house, only suffering the August brood to go abroad, when the crops are off the ground. In general, pigeons live about eight years, but they are only prolific for the first four years; afterward they are worth nothing; and when they are past that age they only prevent the profit that might be reaped from those that are young. It is somewhat difficult, and requires considerable experience, to distinguish their age.

6856. *Pigeon-houses, or dove-cots*, are of several kinds. A small one may be made of a cask, or any boarded box, placed upon a pole or against a wall. A larger one may be a loft in some outhouse, or a house may be built on purpose, or the highest part of any tower or ornamental building may be designed as a pigeon-house. The holes by which they enter should not be too large or too numerous, and should have a little shelf at the entrance; they should have a southern aspect, as pigeons delight in the sun. Great care should be taken to guard against the entrance of rats, which are dangerous enemies. An objection to wooden dove-cots is, that they are too cold in winter and too hot in summer; but this may be in a great measure prevented by making the wood double, with a space of two or three inches between, which will form a nonconductor of heat. The holes should have a piece of weather-boarding over them to keep out the wet.

Fig. 905.



6857. *The interior of the pigeon-house* must have cells for nests; and these may be made by putting up shelves of wood, stone, or slate twenty inches wide and one foot apart, the spaces between being divided by upright partitions three feet from each other. Across the front of each nest there should be a board of three inches wide, sliding up and down in a groove, to prevent the young ones from falling out, which they are apt to do; by having this board moveable, the nests may be cleaned out occasionally. As tame pigeons seldom take the trouble to make any nest themselves, it is proper to make some for them of hay or straw, to be put into the cells; a kind of basket is best. It is recommended to fix a partition of similar height in the middle of each three feet division, thus parting it into two nests: this is to prevent the young from running to the mother when she is sitting over fresh eggs, and perhaps occasion her to cool and addle them; for sometimes, when the young are about a fortnight old, the female, without waiting till they are fledged, will leave them to the care of the male, and lay again; and it is not uncommon to see a fresh hatching going on while the young ones are in the same nest. When the young ones are taken the nests should be cleaned out, and they should be frequently examined, lest any of the young ones should die in the holes, as they will become putrid, and produce maggots and bad smell. Every summer, after the first or spring flight of young, the nests should be thoroughly cleaned out and the dung removed. This should be done in the morning, and the dove-cot should never be entered later than midday; if disturbed in the afternoon, the pigeons will be discontented all night, and perhaps will sit outside, while their eggs are spoiling. The inside of the house should be well plastered, to keep out vermin. Pigeons are generally fed in the open air, adjoining their cot; but when the weather is inclement, or when it is desirable to attach them to their house, both food and water should be given them in it: for this purpose, a small hopper may be fixed outside, from which the food, being put in, can descend into a shallow box within. Pease, the smaller kind of horse-beans, wheat, barley, buckwheat, and oats are eaten by pigeons; pease are the best: old tares are considered excellent food; new tares are reckoned scouring. Water may be supplied in a similar manner by a small bottle of water reversed in a small basin, in the manner of the common bird fountain.

6858. *Pigeons require to have fine sifted gravel*, or coarse sand, as they are in the habit of picking it up to assist their digestion; and if that is not supplied to them, they are apt to peck the mortar from the roofs of their houses or adjoining buildings. The usual mode of supplying them is to place what is termed a *salt-cat* in or close to the pigeon-house. This salt-cat is a jar, with holes punched in the side sufficiently large for the pigeons to get out with their bills the following mixture put into it: a gallon of fine gravel or drift sand; another of lime rubbish of an old wall, or, if none be at hand, lime mixed with sand; a pound of cummin seed, and a handful of salt; the latter two of which pigeons are very fond of; the whole is moistened with stale urine. Strong scents, such as asafœtida, are said to be agreeable to these birds, so as frequently to attach them to their habitations when they will not stay under other circumstances.

6859. *Cleanliness is essential* to the health of pigeons; a neglect of it will cause them to be covered with vermin. The common house-pigeon is little liable to disease, although fancy pigeons, being monstrous productions, are particularly so. Little is known respecting any modes of curing them.

6860. *Laws respecting Pigeons.*—Shooting, or destroying pigeons by any other means, is punishable by a fine of 20*s*. for every bird killed or taken. Any lord of the manor, or freeholder, may build a pigeon-house upon his own land, but a tenant cannot do it without the lord's license. Shooting or killing within a certain distance of the pigeon-house renders the person liable to a forfeiture.

Sect. VI.—Guinea Fowls.

6861. This bird, retaining somewhat of the wild nature of the original, which was from Africa, is apt to wander from home, and of course cannot be so conveniently kept as common fowls. They are remarkably shy, and are apt to forsake their nests if disturbed; but in general their habits and mode of treatment resemble that of the turkey. There are several varieties, but being rather difficult to rear in our climate, and being noisy and turbulent in the poultry-yard, they are seldom kept, and generally more for curiosity than use, though they are excellent for the table, and their eggs, though small, are particularly good. They can seldom be brought either to roost or lay in any house. Like the peahen, they dislike confinement, and generally choose some shed, tree, or bush for their roosting place and nest.

Sect. VII.—Swans.

6862. Tame swans are never kept except there be a piece of water for them to swim in, to which they are a great ornament; and it is necessary that the water should be clear, towards keeping it in which condition they assist. In its food it is very similar to the goose. The swan lays early in the spring, only once a year, and has seldom more than three eggs. The male assists in hatching. They require little attention in breeding, except a small house for their young, for they usually build their nests in some secluded spot near the water, and prefer an island if there is one. They should not be disturbed; and, indeed, so powerful are they, that a stroke of their wing might have a serious effect. The cygnets are dark coloured when first hatched, and do not become white till their second year. Their bringing up is left to the mother, and may or may not have food supplied, according to the locality. They have sometimes been fattened in the same manner as green geese, by those who choose to try them at table: in severe weather, in winter, they require being fed.

SECT. VIII.—PEACOCKS AND PEAHENS.

6863. The pea-fowl require the same treatment as turkeys. Though formerly brought to table, they are not eaten now, their flesh being coarse and ill-flavoured; they are, therefore, kept only for ornament. The tail, which is so eminently beautiful, comes to its full size when the bird is three years old; and some peacocks live twenty years. They subsist on the same food as domestic fowls, but prefer barley; and though they are very destructive in gardens, yet they are useful in destroying all kinds of reptiles. In her hatching, the hen has the same habits as the turkey, and the pea-chicks are extremely tender. It is necessary to keep the peacock from having access to the young, as he is apt to kill them; and he will kill young chickens in the same way.

SECT. IX.—PHEASANTS.

6864. As this bird has not hitherto been perfectly domesticated, and as the flesh of those brought up in the house is much inferior to that of the wild pheasant, they are bred chiefly for show only, for the park, or for very recluse scenes, which they will not readily leave if well fed and not much disturbed. Their beautiful plumage renders them very interesting.

6865. *To stock a pheasantry*, the general mode is to procure eggs from some establishment of this sort, or sometimes they are found in the woods: these are set under a hen that has kept the nest three or four days; a bantam is best. When the hens have sat their full time, which is from twenty-three to twenty-seven days, the young pheasants as they are hatched should be put into a basket with a piece of flannel; after the first day they should be put under a frame with a net over it, with a separate place for the mother: they should be fed with boiled eggs cut small, boiled milk and bread, alum curd, ants' eggs; a little of each sort, and often. After two or three days they will be acquainted with the call of the hen that hatched them, and may have their liberty to run about, observing to keep them out of the sun and the cold winds. It is proper to choose a situation for a pheasantry where they may be well protected from dogs, foxes, &c. Those young birds that are intended to be turned out wild should be taught to perch, by tying a string to the hen's leg, and obliging her to sit in a tree all night, till she becomes accustomed to this situation. The young birds will follow the hen and perch with her. Those for breeding are to be put into a pen, having their wings clipped: such as are to be turned out are put into another pen, netted over, and having their wings untouched. When first penned, the birds must be fed with dough of barley meal, corn, and plenty of green turnips. As the birds are fond of ants' eggs, some should be procured, if possible; and some persons make artificial ones by rolling flour beaten up with an egg. Great cleanliness must be observed with respect to pheasants.

Hen pheasants seldom succeed in rearing their brood, through their extreme shyness; but, to induce them to do so, a retired place must be provided, well sheltered by trees, and having a supply of water. Pheasants appear to show great partiality for marshes near the sea, or cliffs with any furz or cover for them, and which join the salt water; for, like pigeons, they are great lovers of salt. In such advantageous situations, Mr. Daniel says they can be retained plentifully, provided they have abundance of food with perfect quiet; and that, when reared with common fowls, they sometimes become very tame.

SECT. X.—AVIARY.

6866. This is a house for keeping birds that do not come under the description of poultry; such as gold and silver pheasants, partridges, quails, red, black, and wood grouse, turtle-doves, and the rarer pigeons; Muscovy ducks, Canadian geese, bustards, gulls, curious varieties of the fowl, &c.; also singing and other small birds. A large aviary requires an enclosure of some extent—perhaps an acre or two—and in this must be the various houses for the different kinds of birds: these may be small, rustic structures, provided with the conveniences of roosting places, nests, &c. Elegant aviaries may be seen at Woburn Abbey, Bedfordshire; Cobham Hall, in Kent; and Knowlesly Hall, near Liverpool. Some of the birds that are wild require to have small nests or enclosures, covered with netting, to prevent their flying away, and to protect them from birds of prey. The construction of aviaries on a small scale is too evident to require particular description: they must be enclosed with wire netting, and have the usual contrivances for holding food, drink, &c.

CHAPTER VII.

PIGS, AND THEIR MANAGEMENT.

6867. Pigs are not very agreeable to have about a house; and it is therefore desirable that they should be kept out of sight as much as possible, which can only be done where there is some kind of yard. Where cows are kept, it is generally found convenient to have also some pigs. It is well known that the most delicate pork is that produced by feeding pigs on milk and whey from the dairy, with meal; and that it is much superior to any that can be had from the butcher. Nevertheless, if any inexperienced person should set about feeding his pigs for his table, the pork might prove very expensive; and this branch of domestic economy requires some little skill. Even in a farm, hogs are generally considered rather as a subordinate species of live stock, and chiefly valuable as consuming what would otherwise be lost: there is one advantage which this animal has, which is, that his keep usually costs little, and is not attended with much trouble to those accustomed to them.

6868. *There are various breeds of swine*, and some fatten more readily upon the same food than others; and the breeds vary considerably in their size. Those which are reckoned the best of the small kind are the Berkshire and the small Essex, or the latter crossed by the Chinese. Of larger hogs, for bacon, the Hampshire, the Norfolk, and the Cheshire are the principal; and, as porkers, the Suffolk, Essex, and Oxfordshire are among the best. The long-legged Irish pigs are considered to be the worst.

6869. *In purchasing pigs for fattening*, it is not always easy to procure the very best breeds; but some of the others may do very well. The sow should be at least ten months old before she is fit to breed from: she goes with young a little more than four months, and has often two litters in a year, generally producing a numerous progeny, consisting of from eight to sixteen at a litter. Hogs, when suffered to see the natural term of life, live from fifteen to thirty years. Their size and strength continue to improve till they are five or six years old. The best season for their farrowing is in the summer, as young pigs are exceedingly tender and difficult to rear in the cold of winter.

6870. *Pigs are very troublesome in cultivated grounds*, ploughing them up with their snouts in search of wild roots, of which they are fond. To prevent them from turning up the soil, the best method is to cut the two strong tendons of their snouts with a sharp knife, about an inch and a half from the nose; this may be done with little pain and no prejudice to the animal when about two or three months old. The common practice of restraining them by rings fixed in the snout is painful and troublesome; these must be replaced as often as they give way, and that happens so frequently that rings afford little security against this nuisance.

6871. *The piggery should be so situated* as not to be offensive, and yet be easily supplied with food from the scullery and dairy. Each animal requires to have a separate sty, which should open into a little court or area, for exercise, and to hold his feeding trough. The large piggery erected by the Earl of Egremont is said to be one of the most complete in the kingdom.

6872. *The pig-sty* may be built of any convenient material: stone or brick are the best. It should be dry and warm; and for this purpose the floor is best paved with large stones, and should be raised a little above the ground, and slope a little towards a channel conducting the wet into a drain leading to a cess-pool or manure tank: one of the usual defects of pig-sties is the neglect of proper drainage. The roof may be thatched with straw, reeds, heath, or any other warm material. Every piggery should have a rubbing-post for the animals to clean themselves against. When circumstances permit the pigs to have access to a field, or an orchard, or wood, where they can find fruits and vegetables of various kinds, it is of great advantage to their health.

6873. *When a sow is expected to farrow*, she should be separated from the rest, and littered down with a small quantity of dry, short straw; but if too much straw is used when she has young, the latter are apt to nestle under it and be smothered by the dam. Sows should likewise be carefully watched for some days after farrowing, as they are apt to eat their offspring: she ought to be well fed while nursing. The young pigs are generally weaned at the end of six or seven weeks: and, when sows are weaning, they ought to be kept low, and allowed to wallow in wet, as they are at that time very subject to a milk fever.

6874. *Cleanliness should be observed as much as possible with respect to pigs*, although it is an opinion not uncommon among some country people that changing the litter and cleaning the sties protract the time of the animal's arriving at his required degree of fatness; and that filth contributes to his health and prosperity. This opinion is fully contradicted by experiment. Although pigs in general are not clean in their usual habits, yet few domestic animals are more pleased when they have clean, comfortable beds, and certainly none on which cleanliness has a more evidently beneficial effect, so far as feeding and fattening are concerned. Pigs are particularly liable to disorders of the skin, and to vermin, probably from their gross feeding; and cleanliness assists very much to remove these. It is good management to give them occasionally a little sulphur and nitre with their meat: when first put up to feed, some add a small portion of antimony. Some pigs are liable to inflammatory disorders, which are seldom curable. To prevent this, some wash and scrub them every week.

6875. *The pig is a voracious animal*, gross in his feeding, and almost omnivorous. He will devour animal matter, but it is chiefly on vegetable food that he is fed. He will graze, eat cabbage leaves, common and Swedish turnips or turnip tops, carrots, parsnips, and mangel-wurzel: potatoes afford him much nutriment, but should never be given raw, but always boiled, and the water in which they were boiled should be thrown away. Besides this, all the peelings and refuse of potatoes, cabbages, and other vegetables, and greasy slops from the scullery, are made up into a mash for the pigs; and there should be a spout leading out of the wall of that place conveying it into proper receptacles for carrying it to the hog cistern or trough. Pigs will thrive and be in tolerably good condition when kept upon food of this kind; but besides this, there is another stage in his feeding, which is *fattening* him for the butcher. For this, food of a more nourishing quality is requisite; and farinaceous food is found to be more fattening, such as barley meal, pea meal, and buckwheat; these are boiled with milk, or mixed with other kinds of food. If pigs are suffered to gorge themselves with food, they are liable to have surfeit and indigestion, which is removed by abstinence for a day, or giving nothing but a warm mash, with bran or pollard.

6876. *In fattening sucking pigs*, all that is requisite is to keep the mother well lodged and nourished. *Weaned pigs*, when to be fatted, are to be kept constantly on whey, or skim-milk, or butter-milk, with frequently an addition of pease, or beans, or barley meal. Such good keeping makes them increase rapidly in size, and renders them fit for use at an early age.

6877. *When pigs are of a proper age to fatten for pork or bacon*, they are kept in the sty, and well fed with the best food. This must vary somewhat according to circumstances; but certain kinds of food are usually employed for this purpose. Milk, whey, and scullery wash, with steamed potatoes, meal of barley, pease and beans boiled with milk, are all fattening materials; also Swedish turnips and carrots boiled or steamed. Potatoes, if raw, are of little use to fatten, and hence the inferiority of the greatest part of the Irish bacon that comes to market; they are much more nutritive if boiled. Grains from the distiller are likewise used where they can be obtained; and here it may be proper to notice an error respecting the last. It is a general idea that distillers' grains are the cause of a constant intoxication of the pigs, and hence that their flesh cannot be healthy; but it is a mistake to suppose that there is any spirit left in the grains; observation has shown that pigs fed upon such food are quite as healthy as any other. Bacon, however, fatted upon porridge of barley meal and skim-milk, is the finest.

A pig may be fattened in about six weeks or two months. Young porkers are generally fattened between October and Christmas; if fed on boiled pease or beans, or meal from them, for the last fortnight, the flesh and fat will be firmer. A little salt sprinkled with their food will often make them relish it better. There is no necessity that the wash from the scullery should be always given fresh; on the contrary, pigs seem to prefer that which has been accumulated, and kept a little so as to be stale or sourish, and perhaps beginning to ferment, on which account some recommend having several tubs or cisterns to collect it in, so that one may be emptying while another is filling.

6878. *The hog cistern* for containing the wash is best made of stone or slate; wooden vessels are liable to decay, and lead is dangerous. Some have been made of brick and Roman cement, or bricks laid in strong ferruginous clay, lined with a coat of the same, so as to be perfectly water-tight. A slanting shed roof should be placed over them, and it may be sunk in the ground with advantage, to prevent freezing in winter.

The feeding trough ought to be kept very clean, and frequently washed out with hot water.

6879. *Where a single cow is kept, much cannot be expected from her for the pigs;* and yet many a cottager contrives with that, and the refuse of his garden, with offal of his kitchen, not only to keep one, and perhaps two, but to fatten them tolerably. When little more than potatoes are employed to fatten, the quantities requisite have been stated thus: To feed a pork pig of 8 stone, or 128 lbs. weight, allowing a peck a day in 15½ bushels, very little oatmeal or barley meal will be necessary. A pork pig of 6 stone, or 96 lbs., may be fattened by 11½ bushels of potatoes at 1 peck a day. A bacon pig of 20 stone, or 320 lbs., will require 38 bushels of potatoes, and a load of oatmeal or 16 stone weight. With one cow, two pigs may be kept with good management.

CHAPTER VIII.

RABBITS.

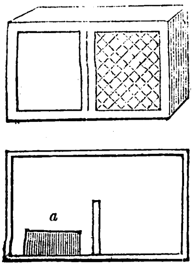
6880. Rabbits are not only kept in a domestic state, but also largely in a wild state in warrens, particularly in sandy districts. A warren is an enclosed piece of ground where the rabbits live in holes which they burrow beneath the surface, as it exists naturally; or in banks raised artificially for the purpose: level ground is not fit for a warren, these animals, in their native state, delighting to burrow in the sides of sandy hills. It is essential that the soil should be dry, sandy and poor; a damp situation will be fatal to the stock, as they are very liable to the rot; and too rich herbage is unfavourable to their health. In the winter season, when the weather is severe, food must be supplied to them, consisting of green hay, turnips, and other vegetables. The wild rabbits are taken in the warrens by nets or traps, and sometimes by terriers: they are in season from the end of October to the beginning of January, and are better as food than tame rabbits. There is seldom any other variety kept in warrens than the gray. Vast numbers of these wild rabbits are sent to the London markets in the winter months, and sold at a very cheap rate.

6881. *Tame rabbits* are reared in rabbit-houses, or in hutches: there are several varieties of them; the large white and yellow species, and a larger variety of the hare colour. These and other varieties may be had of the London dealers and poultrymen.

6882. *The doe will breed* at the age of a year, and sometimes in six months, and her period of gestation is thirty or thirty-one days. Some days before parturition hay is to be given her to assist in making her bed, to which she adds the flue which nature has instructed her to tear from her body for that purpose; forming this bed is the first sign of pregnancy. There are generally from five to ten produced at a litter, but if any of these appear defective or sickly, they are usually destroyed, five being as many as she can well rear: at the end of six weeks they may be separated from her and weaned. The buck should be kept at a distance while she is nursing the young, or he will kill them. Should the doe be weakly during nursing, it is common to give her more nourishing food than usual. With due attention in keeping them warm and feeding them well, rabbits may be bred throughout the whole year, though four or five litters may be considered sufficient.

6883. *The rabbits' hutches*, in which they are kept, are wooden houses, *fig.* 906, two feet six inches or three feet wide, and one foot six inches high, divided into two by a partition within that has an opening forming a communication between them; the use of this division is, that the rabbits may be confined in one while the other is being cleaned out, which must be done frequently, otherwise the animals will become diseased. Each division should have a door, and one of them may be wired or fitted with bars an inch apart, two of which should be moveable, to put in food. The food is put into a trough, *a*, which should be of pewter, iron, or earthenware, as rabbits are apt to gnaw them when of wood. Their grass and greens may be laid on the floor. These hutches are ranged in the rabbit room along the wall a few feet from the floor, or in any other way that may be found convenient, the apartment not being always intended for the rabbits to run about in; though some prefer this, if there are but few.

Fig. 906.



6884. *The food of the rabbit* is entirely vegetable. They feed upon common grass, clover, lucern, and on good hay, and pea and bean straw; greens and roots form excellent food, and potatoes boiled or steamed. They will fatten upon them, but still more if they are given corn and pollard. Some think that the flesh is less dry when fed chiefly upon succulent herbs; but with these moist foods they must always have a proportionable quantity of the dry foods, as hay, bread, oats, bran, grains, chaff, and the like, or they will become pot-bellied, and die. This food may be given three times a day; and when they have greens, they must not have drink; at all times they drink but little The test of health is their dung being not too moist.

6885. *Rabbits are in perfection for feeding* at the fourth or sixth month, or much less sometimes, if they are given farinaceous food.

6886. *The diseases of rabbits* are not numerous, if moderately taken care of; keeping them too much on green food will, as has been stated, cause them to be pot-bellied, the cure for which is changing their diet by giving them hay and corn, ground malt, or pease, or any farinaceous food. They are also liable to liver complaints, which are incurable Fattening should not be pushed too far, otherwise they will sometimes drop off suddenly.

CHAPTER IX.

APIARY, AND MANAGEMENT OF BEES.

6887. The natural history of bees, with their divisions into queens, drones, and working bees, is so interesting that it has been treated of in an ample manner in a variety of popular books: it is not necessary to repeat it here, and we refer the reader, for the nature of honey and wax, and the manner of their production by the bee, to Book VIII., Chap. XIV., "On Honey," and to Book IV., Chap. II., "On Wax." We propose at present to confine ourselves to the methods of managing and preserving the stock of bees in their hives. In modern times, the importance of bees has suffered a considerable diminution in consequence of the introduction of sugar; still, this part of our economy is cultivated with considerable care, and improvements have lately been made in it.

6888. *The locality and particular situation* where it is proposed to keep bees must be considered with reference to their natural food, and whether it is likely to be in sufficient abundance. The spot selected for placing the hives should be well sheltered, and have a southerly aspect, with garden herbs, and flowers, if possible, in the vicinity. Foul smells and loud noises have been thought annoying to bees, and hence it is deemed advisable never to place them in the neighbourhood of forges, pig-sties, and the like. This opinion with respect to noises, however, is doubtful, since they do not appear to be furnished with the organs of hearing.

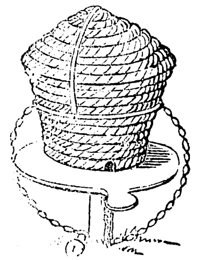
6889. The advancement of agriculture, and the consequent decrease of wild flowers, with the enclosure of wastes and commons, have been unfavourable to the keeping of bees; and in an arable country, with good farming, few stocks can be supported. Near large tracts of heath land, where the flowers of the heather furnish an ample supply of food, bees generally thrive. In Germany and Switzerland it is not uncommon to transport bee-hives into these places during the summer season; this change of situation is effected in some parts of France by means of boats on the rivers. Bees are supposed to range a mile or two in quest of food.

6890. *To establish an apiary*, it is necessary to procure, by purchase or otherwise, a hive of bees, or as many as are required to commence with. Common straw hives with bees will be sufficient. The hives should be selected by a skilful person in a cool evening, or very early in the morning: the spring is the best season: he will be able to form a tolerably good idea whether or not a hive is full of bees and combs by tapping on it. The hives may be easily moved by placing a square board under each, and putting it upon a cloth, which is to be drawn up all round it; then carrying it upon a man's head. When brought home, the hives may be placed on stands, or in a bee-house; this may be a wooden closet raised on feet, and having doors opening in the front and sides; it may be four feet wide and six feet high, with three shelves, each large enough to hold two hives, with a slanting roof to turn the wet. The holes for the entrance of the bees should be three inches long and a quarter of an inch high, with a little shelf before each, for the bees to light upon.

6891. *Bees require a warm temperature*; and it is said that neither the larvæ nor chrysalis will live in cold of 60°. They appear to have the faculty of perceiving the approach of cold weather and rain, and even while busy abroad at their work, they will suddenly leave off, and hurry home in crowds, till the doors of their habitations can scarcely admit them fast enough; and they are seldom caught in a shower, unless at a great distance from the hive. Cold is a great enemy to them; and in this climate their hives must be kept well sheltered and warm: to defend themselves against it in a hard winter, they crowd together in the middle of the hive, and buzz about, exciting a warmth that may be perceptible by laying the hand upon the glass window of the hive. Sometimes, in very cold winters, they form clusters, hanging on each other, and continue for some time in a torpid state. When they appear to be dead with cold, they may be frequently revived by laying them on a cloth at a distance from the fire, or by applying artificial heat to them in some other mode. Mild winters, as well as severe cold, are often injurious; sunshine in winter tempts them to go abroad, and exposes them to a change of weather.

6892. *Bee-hives* have been made of various forms: the common form answers in general, is well known, and easiest procured. Hinsh recommends that represented in *fig.* 907. Instead of having three or four legs, as is usually the case, a single one is preferable, as being a better protection from vermin and insects: the hive may be chained down and locked. It should be placed about two feet from the ground when on a separate stand. The fittest material is straw, which affords the best defence against the extremes of heat in summer and cold in winter; this is, in general, preferable to wood, though some ingenious kinds have been constructed of this substance. Hives, with glass, have been made for the purpose of studying the habits of the bee, but only with this view. A superior kind has been invented by Mr. Nutt, and is described in his work on bees. The size of the hives should correspond, as nearly as possible, with that of the swarms. Bees will endeavour to fill with combs whatever hive they are put into before they begin to gather honey. Owing to this, when a hive is too large for its inhabitants, the time for collecting their winter store is spent in unprofitable labour, and starvation is the consequence. This evil also extends to occasioning late swarming the next summer; it being long before the hive becomes so filled with young bees as to produce a necessity for emigration, from which cause the season is too far advanced for the young colonies to procure a winter stock. A full-sized straw hive will hold three pecks; a small-sized one from one and a half to two pecks.

Fig. 907.



When there are many hives, it is usual to collect them together in a bee-house, or apiary, for the greater facility of protecting them from the cold or thieves, and greater facility in examining their condition and progress. It may consist of a wooden closet, as above mentioned, or merely a simple recess in a wall exposed to the south, and with shutters to exclude the sun occasionally in summer and the cold in winter. The hives are often placed in the kitchen garden, where they are considered as useful, by aiding the impregnation of flowers.

6893. *The swarming of bees* generally commences in June; in some seasons earlier, and in cold climates or seasons later. It is preceded by their hanging in a kind of string. Hives should, if possible, be placed in the neighbourhood of gooseberry or currant bushes, rather than of large trees, as the bees are sure to fly to the first tree they can find.

When the bees are observed hanging together in a string, they should be carefully watched till the swarm has settled, which it generally does on a bush or tree, when a new, clean hive should be brought and placed over the bees for them to go up into; or the swarm should be swept into the hive, which must be immediately carried to the place where it is to stand. It sometimes happens that the swarm will leave the old hive and return again several times, owing to the queen not having accompanied them, or from her having dropped on the ground, when too young and weak to fly to a distance. It was formerly the practice to wash the hive with beer, or sugar and water, and, after the bees were hived, to let it stand till evening before it was removed to the place where it was to remain; but both these practices are now thought unnecessary, and the latter even injurious. Should the weather, for some days after swarming, be unfavourable for the bees' going out, they must be fed with care until it clears up, otherwise the young swarm will run a risk of dying.

6894. *The honey is taken from the hive* in two different modes. The most ancient, and still the most usual mode, is by suffocating the bees, which is done in the following manner, in the autumn, generally in October: Linen rags smeared with melted sulphur are introduced to the hive by placing it in a hole in the ground, where a few shreds of this article are undergoing a smothering combustion; or the full hive may be placed on an empty one inverted, and the sulphureous smoke introduced by a fumigating bellows. The bees will fall from the upper to the lower hive in a few minutes, when they may be removed and buried, to prevent resuscitation. The combs, being thus cleared of bees, may be cut out. Although this practice has been mentioned as cruel, it is, in fact, not more so than any other way of killing animals for food, and it would be impossible to preserve all the swarms, as the bees would multiply too fast. However, where the preservation of the lives of the bees is an object, another method is employed, by which only a part of the honey is taken, about September. It is effected as follows: Having ascertained the weight of the hive, and determined on the quantity of honey-comb that is to be extracted, begin the operation as soon as evening sets in, by inverting the full hive, and placing an empty one of exactly the same diameter over it. A table-cloth must be tied round the whole, to prevent the bees from molesting the operator. The hives being thus arranged, beat the sides gently with a stick, particularly in those parts to which the combs are attached, which are parallel with the entrance of the hive. The bees will then ascend in a few minutes into the upper hive, which will be known by a loud humming noise; or this transfer of bees may be effected by a slight fumigation with burned paper. When the whole community has ascended, the hive with the bees may be placed upon the pedestal from which the full hive was removed, and that from which the bees have been driven may be taken into the house to have the comb extracted. Particular care must be taken to cut out only one comb at a time; not to take too much. Having thus obtained a sufficient quantity, the hive may be placed over that containing the bees, which must be reversed, and both left in that position until the next morning, when the bees will be found to have taken possession of their former hive; and if the season proves fair, they will be able to make another quantity of comb and honey equal to what they lost. If the honey is taken early in the season, immediately after the first swarm, the whole of it may be cut out, and the bees, being returned into the emptied hive, will, perhaps, be able to make honey enough afterward for their winter stock; but it is to be observed that, in this case, the hive cannot be expected to be full of honey, because the bees, in June and July, are chiefly occupied in breeding, and by this method one, if not two swarms are lost. Various other contrivances have been invented for taking the honey without destroying the bees, but their description would demand more details than our limits will allow, and we must refer the reader to works written expressly on the subject, as Bagster on Bees, 1834; and Nutt's work on the same.

By managing the temperature of the hives, Nutt prevents young bees from being produced, and, consequently, no swarms can take place, which often occasion so much trouble. It appears that under a certain degree of heat the queen will lay no eggs, nor would they be hatched, although the collecting and storing of honey will go on at this low degree of heat; the hives are, therefore, kept cool by ventilation. That ventilation is important to the health of the bees there can be no doubt; but the swarming being natural to bees, it is impossible altogether to prevent it. There is some difference of opinion respecting the utility of Nutt's boxes, the advantages of which are thought to be exaggerated, though they are certainly more elegant and convenient than the common ones, where amusement chiefly is the object.

6895. *To protect the ordinary hives from the cold*, they are covered with a thatch of straw or rushes about the end of September, according to the climate and season. This is very essential, and well-covered hives are always in a better condition the following spring than such as have not been covered. In October, the aperture at which the bees enter should generally be narrowed, so as only to admit of one bee passing at a time. Indeed, a very small portion of air is sufficient for them in winter, when they are mostly in a torpid state; and it were better for them, during severe frosts, to be entirely shut up, as numbers are often lost from being enticed to quit the hive during the sunshine of a winter day. It will be proper to remove, by a crooked wire, the dead bees and other filth, which the living at this season are unable to perform of themselves. To the hives whose stock of honey was sufficient for their maintenance, or those to which a proper quantity of sugar had been given for that purpose, no farther attention will be necessary until the breeding season arrives; this, in warm situations, generally takes place about the beginning of May; and in cold, about a month after. The young bees, for a short time previous to their leaving their cells, and some time after, require being fed with the same regularity that young birds are by their parents; and if the store in the hive be exhausted, and the weather such as not to admit of the working bees going abroad to collect food in sufficient quantity for themselves and their brood, instinct impels them to kill and throw out some of the larvæ. To prevent such accidents, it is advisable, if during the breeding season it should rain for two successive days, to feed all the bees indiscriminately, as it would be difficult to ascertain only those which required it.

6896. *It is sometimes necessary to supply the bees with food early in the spring*, should they have consumed their winter's stock, or if kept during the winter, after their honey is taken. This should not be deferred too long; the hives should be examined in September, and if a large hive does not weigh thirty pounds, it will be necessary to allow it half a pound of honey, or the same quantity of soft sugar made into sirup, and less in proportion for smaller hives. It is sometimes the practice merely to dissolve sugar in water, but without boiling it into a sirup; but this does not answer properly, for, when the water evaporates, it leaves the sugar to crystallize, and in that state the bees cannot act upon it. A sirup is a closer combination of sugar with water, by which the latter is prevented from flying off, the consistence resembling honey. Some recommend a plate of diluted inferior honey crossed with straws, and covered with a paper pierced with numerous holes, through which the bees will seek the honey without daubing themselves.

6897. *When honey is scarce in the hives* early in the spring or late in the autumn, and there are no flowers to furnish them with more, and the bees have ranged the fields without success, they will endeavour to supply themselves, at the hazard of their lives, from the stores of other bees; and conflicts sometimes occur in consequence of depredations on neighbouring colonies, which frequently terminate fatally to many of their number.

6898. *The best remedy for the sting of the bee* is stated in the Quarterly Review. "Extract at once the sting, which is invariably left behind; if a watch-key is at hand, press it exactly over the wound, so that much of the venom may be squeezed out; and in any case apply, the sooner of course the better, laudanum, or the least drop of spirit of ammonia. Oil and honey, which are also recommended, probably act in keeping off the air from the wound. The cure varies much with the constitutions of individuals; but the poison being acid, any alkali will probably be serviceable."

6899. *Those who wish to amuse themselves with bees* should study their habits; it is remarkable how easily many bee masters can manage them. In particular, they cannot bear to be breathed upon.

CHAPTER X.

FISH PONDS.

6900. It is much less the custom to keep fish in ponds at present than it was in former times, when the Roman Catholic was the established religion of this country, in consequence of which fish was almost an essential article of food two days in the week, and for which reason fish ponds are still very numerous on the Continent. At that time, also, the communication between the seacoast and the inland parts of this kingdom was much more difficult than at present.

The situations in which fish ponds are most easily formed is in a small, narrow, steep valley, through which a stream of water runs. By building a dam across the valley, the water is stopped and collected, and a pond is formed without any farther trouble. Several such ponds may be made by collecting the water that overflows by similar dams lower down, provided there be water enough. In other situations, ponds must be dug, and made water-tight by clay or some other material; a soft, marly, or muddy bottom is best, with a warm exposure.

6901. *The kinds of fresh-water fish generally kept in ponds* are, carp, tench, perch, gudgeon, eel, and pike. Of these carp is the most useful; they multiply fast, and grow to a large size. Under the best system of management three ponds are required, one for breeding, another for rearing, and a third for fattening.

6902. *To stock a pond*, full-grown fish should be put in early in the spring, the season for spawning being from the latter end of May till the beginning of July. When the fish have spawned they should be put into the feeding pond, and the young fry should be left to themselves till the spawning season next year; they are then removed into the rearing pond, where they remain for two years, when they will have grown to the length of four, five, or six inches. This pond is then drawn, and all the fish above five inches are put into the feeding pond, from which the largest are taken as wanted for use. The natural food of carp consists of larvæ of insects, worms, and soft aquati plants; but to obtain these fish of a large size, they are fed in stews in rain-water, on garbage, boiled potatoes, rice, bread, or any soft food. Carp will grow to the weight of three pounds in six years, and six pounds in ten years, and they have been known to exceed that considerably. They are in season from October to April. In very large ponds, such as they have on the Continent, scarcely any food is given. Tench are generally put into the same pond with carp, as is the case in Berkshire, where there are many fish ponds. They will live in foul, stagnant water in which no other fish can exist: this occasions them to have often a muddy taste when cooked for table, except they are kept for about a week previously in clean water. Perch require cleaner water than either carp or tench, and the pond in which they are kept ought to have a stream running through it; but they will thrive in stews if the water is kept clean; they grow sometimes to the size of two feet. Gudgeons are small fish, and, being much inferior to carp or tench, are reared chiefly as food for pike and perch. Eels will live in stagnant water, and require a pond through which there is some current, as mill ponds, but may also be kept in stews; in ponds they are destructive to other fish. The pike is a very voracious fish, and requires to be kept by itself; some grow to the size of several feet; in default of other fish as food, they will devour any small animals.

6903. *Salt-water fish* of several species can be preserved, and even fattened, in fresh-water ponds, particularly the flounder and other flat fish of the genus Pleuronectes, the mullet, &c. Lately some experiments of this kind have been attended with complete success. See Brande's Quarterly Journal, Nos. 33 and 34.

BOOK XXVI.

PRESERVATION OF HEALTH, AND DOMESTIC MEDICINE.

CHAPTER I.

HEALTH IN THE NURSERY.

SECT. I.—GENERAL OBSERVATIONS.

6904. *Health in infancy and childhood* will always form a consideration of deep interest to parents. Their earliest solicitude must always lead them to seek the means of developing in fair proportion all the infantile powers, bodily and mental, of their offspring. These means are comprehended in the term "good nursing," or, in medical language, "physical education." Maternal attention and foresight should always be directed to this subject; for "bad nursing," the mismanagement or neglect of the bodily powers of children, is often the foundation of diseases in infancy, which leave permanent effects in the constitution, or bring forward diseases which might otherwise have always remained latent, thus blighting all the enjoyments of life that result from good health; besides which, so connected are the physical, intellectual, and moral systems of human nature, that in no individual can one of them be impaired without danger to the others. The wisest system of education may never be sufficiently effective to eradicate the evils of "bad nursing."

6905. If any of the following details and observations appear applicable chiefly to the affluent conditions of life, or comparatively useless to those whom pecuniary considerations would restrict in their domestic arrangements, still there will be found suggestions of a general description, and applicable to the common nature of childhood—suggestions which may serve for any sphere of life in which sensible, active mothers devote themselves sufficiently to their maternal duties. Such mothers may bring up as fine, healthy, happy children as the most expensively appointed nursery can display; and even more so, for luxury and indulgence are not in themselves at all favourable in their influences over childhood.

6906. *Children, under all ordinary circumstances,* may be brought up in the wholesome habits of cleanliness and activity; may be taught self-restraint in regard to food; may be encouraged in cheerful, enlivening pursuits; their minds may be awakened to useful observations, even by the simple exercises essential to the development of their bodily organs. These are the principal influences promotive of infant health and vigour; and by these a merciful Providence has rendered the welfare of childhood independent of the gradations in wealth and rank that are caused by the varying circumstances of civilized life. Thus mothers, employing wisely the means of good nursing which nature intrusts to all alike, may look with indifference, as mothers, on the useless appendages and luxuries with which they may be unable to surround their children: may they not also rejoice, if, while their condition denies their children privileges which affluence might yield them, it also screens them from snares and temptations most fatal to their best interests?

Without farther observations, we proceed to details regarding the rearing and management of infancy and childhood—subjects of deep interest to all who have the responsibility of parents.

Sect. II.—Arrangement of Nurseries.

6907. In addition to what has been said in Book III., "On Ventilation," we may add that *nurseries*, or any rooms appropriated to the use of children, should be lofty, airy, dry, light, and cheerful, if possible, and not on the ground floor, where the rooms would be more liable to be damp, and the air altogether less pure, than may be expected in the higher parts of the house. Whenever practicable, children should have their day nursery as well as that in which they sleep, that each room may be in turn thoroughly ventilated. [This and the accompanying suggestions, however valuable to the families of the English nobility, and to those possessed of overgrown wealth in any country, are adapted but to a very inconsiderable number in America. The luxury of both a day nursery and a sleeping nursery, distinct from the apartments occupied by the family, could be provided in few houses in this country, however large. And there are, moreover, valid objections of a moral nature to so complete a separation of infant children from the maternal eye and hand as such arrangements contemplate. The children of the humbler portion of the population, and even of the poor, with all their privations of separate nurseries, are more than compensated for their absence by maternal care, instead of having their nurture performed by proxy, even with the best qualified nurses, a blessing rarely realized, even among the rich. Without detracting from the excellent suggestions of the author, which are meritorious and valuable for those to whose position and circumstances so extensive and expensive a domestic establishment is practicable, we may, nevertheless, felicitate ourselves that, even without separate nurseries, the *ventilation*, *cleanliness*, and *temperature* of the apartments occupied in common for all the purposes of the family, as they are of necessity by multitudes in our crowded cities, may all be secured by the skill and ingenuity of our American housewives. Such mothers abound in our country, who, without "wet nurses, or head nurses, or under nurses, or nursery governesses," train up families of children, whose physical and moral training, and whose exemption from disease and death, would favourably compare with those of parents who can surround their children with this army of nurses, by reason of their wealth, and luxurious self-indulgence, often indulged by such mothers, at the expense of augmenting the fearful bills of infant mortality by the sacrifice of their own offspring.] On this one circumstance health during childhood much depends; for it cannot be preserved wherever fresh air is excluded. In children, impure air brings forward constitutional diseases, which might otherwise have continued latent. Fresh air invigorates and enlivens children; pent-up air weakens and depresses them. Day nurseries should be prepared for the children, by having the windows open early in the morning, whenever the weather admits of it. A short time suffices "to change the air" of the room, to use a common, but not very correct expression. When the children enter it, with its freshness it should brace their young nerves, perhaps relaxed by the pent-up air of their sleeping room, and they will appear in physical happiness to resemble all other young animals, free and sportive. But let them be brought out of one heated and close room into another, and they will evince all the lassitude of which bodily fatigue would occasion them, and that depressed state of their animal spirits which real weakness would cause. Such temporary effects of close-heated rooms would cease to be transient if the cause were to continue; settled indisposition and debility would ensue.

6908. Yet, desirable as fresh air is, there are some precautions to be observed in admitting it into children's rooms. To continued draughts of air no children should be exposed, unless they are running about the room, or in some way actively engaged. While sleeping in their cribs, or sitting down, they should be always sheltered from streams of air. When awakening from sleep (often in a state of perspiration), any sudden check occurring to them from a current of cold air might bring on some inflammatory attack of the lungs or bowels.

6909. *In foggy or rainy weather* nursery windows should be kept closed. In such a state of the weather the admission of air to children's rooms must be through open doors instead of open windows. Also, in the winter, at three o'clock in the afternoon, should every nursery window in day or sleeping room be closed. Night air cannot be safely admitted into nurseries scarcely at any time of the year. Children should not be permitted to sleep in smoky rooms, nor in rooms in which there are no open chimneys. The difficulty of ventilating the latter rooms is great. The air is gradually vitiated, and must be breathed several times, causing feelings of languor and general depression, and operating as a powerful and hurtful sedative to the animal system. (See Book III., "On Ventilation.")

6910. *The temperature of nurseries* is another point requiring regulation. In nurseries, extremes of heat or cold are equally to be avoided. Excess of heat in the air of rooms in which children chiefly live causes in them relaxation of the skin, irritation in the nervous system, extreme susceptibility to cold, and, in the end, general bodily debility. *Heat* constantly acting on the human frame is said to be more destructive to its vital powers than any other external agent. Sometimes children are suffered to remain, perhaps to sleep, in rooms recently scoured, or in which quantities of wet linen are hung to dry before large fires. The evaporation from the wet floors or linen going on more rapidly in an overheated room than in one of lower temperature, still more debilitating effects may be looked for than the heat without the moisture would have produced. A little moisture in a hot room may not be objectionable—it prevents the air from becoming too dry; but in excess, damp adds to the nervous exhaustion caused by overheated air, and renders children who live in such a state of the air not only more susceptible to cold, but even more liable to the diseases incidental to childhood, which are all, more or less, of an inflammatory kind.

6911. *Excess of cold*, on opposite grounds, is not without danger to children. Great heat over-stimulates, excessive cold depresses their nervous energies. The glands of children, who cannot take the vigorous exercise which adults may do, become by severe cold inactive and humid, and the fluids of the body all but stagnant; hence chilblains occur (see "Chilblains"), with other more serious diseases. These observations, if just, render the temperature of nurseries an important point in their management.

The temperature recommended for the sleeping apartments of children is from 60° to 66° of Fahrenheit. In a lower temperature than 60° the life of a very young infant could hardly be sustained. Living in a much higher temperature, its system would be for a time stimulated, and in the end debilitated.

6912. *To cleanliness in nurseries* great attention should be paid, both as it regards the health of children and the habits to be formed in them. *Nurseries* should be swept daily: damp tea leaves sprinkled on the floors before they are swept prevent the dust from rising much above the floor and settling on the furniture. Children, young infants especially, should be removed into other rooms while any sweeping in their nurseries is going on. It cannot be good for them to breathe air filled with particles of dust, nor are the eyes of infants uninjured if exposed to it.

6913. *Nurseries*, in very damp or cold weather, or in winter, should not be scoured weekly; instead of which, the floor should be merely wiped over with a damp flannel, and then rubbed with a hard brush. No children should remain in rooms damp with scouring, for reasons already stated.

6914. *Bedsteads and cradles* should be kept free of dust, and particularly the floors under them. Fleas or other insect annoyances increase whenever this cleanly process is neglected; and as they often cause children to be fretful, from the irritation their bites occasion, any neglect in daily collecting and removing the dust from beneath bedsteads and drawers should never be permitted.

6915. *Children's bedding, blankets*, and *sheets* should be exposed daily to an open window in fine weather, or to a fire in the winter. Bed linen should be changed at least once a fortnight; in many nurseries it is changed once a week. Carpeting in nurseries, it nailed to the floor, should be swept daily, tea leaves being previously sprinkled over them.

6916. *Nurseries, in their fitting-up and furniture*, can scarcely be too simple and plain. A boarded floor, provided it be not old and full of splinters, is in some respects better than a carpeted floor in rooms in which children play and run about.

6917. *Matting* is soon worn out by the incessant treading of children.

6918. *Carpets*, if used in nurseries, should be kept free from dirt, by being often taken up and shaken out of doors, or daily swept.

6919. *The walls of nurseries* are more generally papered than painted. Many persons, however, are in favour of finishing the walls of nurseries by painting them in distemper, that, in case of the infectious diseases incidental to childhood breaking out among children, the walls of their nurseries may be more easily purified from infection than if papered. In the case of scarlet fever, infection seems to linger for months, and even years, in the house in which it has been, and no means are more effectual in getting rid of this evil than that of whitewashing the ceilings, and, if the walls are distempered, of having them also done afresh. It takes but little time to do them, and but a slight expense; otherwise a papered room is, to the eye, preferable to any other mode of covering the walls of children's apartments, and in the present day the expense of papering rooms is as moderate as any other mode of finishing them. Health, however, is to be considered in every thing as the first object in rooms allotted to children.

6920. *Furniture of wood*, in nurseries, should be made as free from angles as possible; tables should have the corners rounded off, that an infant's efforts to run alone may be as little as possible discouraged; and that children may run securely about their nurseries is most desirable, for indolent nurses would often compel them into sedentary habits and pursuits when nature would incite them to active amusements, if there were any necessity to watch them constantly. Above all precautions should be those regarding open windows and fire-places. Nurseries should never be without bars to the one and guards to the other. The agility and caprice in the amusements of children (together with their inexperience of peril, which makes them fearless) often place them in imminent danger, allowing scarcely time for the most vigilant eyes to perceive, or for any one to avoid it; hence no preventive means should be neglected to preserve them from the effects of their own rashness.

6921. *A well-ordered nursery* should be furnished with everything requisite for children's use, distinct from those of the family. The nursery servants having these things in charge to keep clean and in order, much disputing and confusion among the servants generally are thereby prevented. Breakfast and tea things, spoons, tea-kettles, trays, candlesticks, &c.; tin or earthen-ware baths; *night lamps*, over which are suspended small pannikins, in which, at night, the food of weaning or dry-nursed children may be quickly warmed, though some condemn this practice altogether; washing-tables, made of a height suitable to young children; low chairs, and stools, are among the chief things really required in nurseries: additional conveniences and comforts might easily be named, but can scarcely be mentioned as requisites. See wood-cuts of many of the articles of "Furniture for the Nursery," in Book V., Chap. XIV.

6922. *Closets, cupboards, and shelves* should be found in every nursery, that there may be places into which every article not in use may be put away. It is remarkable how strong a love of neatness and order may be inculcated in childhood by neat, orderly habits in the nurseries in which it is reared, to say nothing of the comfort those habits impart to both children and nurses. When the nursery is littered with the things provided for its convenience, children can hardly play or move about without doing some mischief; and being often reproved for the injury thus done, they certainly suffer from carelessness and untidiness not their own.

6923. *Night nurseries* require little furniture beyond bedding and utensils for washing and bathing. *Carpets* many persons decidedly object to have in the sleeping nurseries, using such as may be easily taken up and shaken daily. In illness they should, in all general cases, be removed; hence it may be best seldom to have any but such as can be easily taken up.

6924. *Cribs*, or small bedsteads from three to four or four feet and a half long, and two feet and a half wide, and having rails at the sides, heads, and feet, put into frames which are fitted into grooves, so that they may be drawn out at pleasure, are at present more in use for children's beds, and for various reasons are preferable to the swinging cots. These last were introduced as substitutes for the rocking cradle of wicker-work formerly seen in every nursery; but which, with the swinging cot also, are now very little used. The objection to both arises from the power they give to nurses to overrock infants, according as their own convenience suggests to them, and renders them inattentive to those symptoms which infants evince when they have slept enough; the nurse will often be tempted to apply to the rocker to reinduce sleep in the infant under her charge before seeking into the causes which have disturbed it. But *if rocking cannot* be effected but in her arms or on her knees, it will be for her own comfort, as well as for the good of the infant, to ascertain, previous to any attempt to make it sleep again, whether its wakefulness arise from hunger or pain, from weariness of one posture, or from restlessness occasioned by too much heat of the room or weight of bed-clothing, or the reverse, for children cannot sleep well when either too hot or too cold. To remedy any of these inconveniences to the infant will be, in the end, less troublesome to the nurse than to hush in her arms the roused infant; but the case may be otherwise, and often has been, when the rocking cot has been at hand; the poor child has been then less considered than it ought to have been, and for such reasons the swinging cot, as well as the cradle of old, has almost fallen into merited disuse. Excess of rocking or swinging is on another ground objected to; it is supposed to induce in infants water on the brain; whether this supposition is well founded or not, the other objection previously observed will be sufficient to keep in disuse all rocking cots and cradles.

6925. *The bedding of cribs* should be soft and warm, and the covering as light as it can be consistent with the requisite warmth during cold seasons. After the first year a horse-hair or good flock mattress is better for children than feather beds, unless in cases of delicate, thin children, whose feeble circulation seems to stand in need of more indulgence in warmth than the more robust. But soft feather beds, with high bolsters or pillows, are supposed to admit of children lying in positions unfavourable to the spine, the feathers being too yielding: a mattress, on the contrary, does not give way to any curved position of the child. In mentioning this evil of feather beds, it is proper to remark that curvature of the spine is less the result of position than is usually imagined; and even admitting that feather beds favour it, they do so rather by contributing to a general diseased system than by any facility which they afford to what might be regarded improper positions. The bodies of young animals, left to themselves, never can suffer from such a cause. The superiority, however, of mattresses over feather beds for children is undoubted. In all cases, in hot weather, mattresses must be preferable for children's use to feather beds: in winter only may the latter be more desirable, as before observed, for feeble infants.

6926. *Blankets* for children should be light, soft, and woolly; of such are those which go under the name of Witney blankets. Those of Lancashire manufacture are heavy and close in fabric.

6927. *Sheeting* for children should be of soft linen or fine calico. The latter is now more frequently used than linen; it is less expensive in the purchase, but is not equally economic in regard to its durability. This can be of less moment in children's sheeting than in that for the family use.

6928. *Counterpanes* can scarcely be too light in texture. They should never be used for warmth, but merely as a protection of the blankets from dust and dirt during the day. When warmth is to be added to bed-clothing, it should be by means of additional blankets. The weight of counterpanes is an objection to them in all cases, and particularly for children, whose breathing should not be oppressed by any external covering either by night or by day.

6929. *Hangings and valances* to children's beds are not needful, if cribs are so placed as to be away from streams of air either from windows or doors. There should always be free circulation of air around the beds of sleeping children; and, so far from having valances to the bedsteads, their cribs should stand on legs about a foot and a half above the floor, that the lower currants of air may pass under, and prevent any stagnation of air beneath the beds.

Management of new-born Infants.

[The birth of an infant is an event which, in almost every family, awakens the liveliest interest and the keenest sensibilities of the human heart. Not only the parents and members of the immediate family manifest anxiety and concern for the safety and health of the little stranger, but the nurse is a most important personage on such an occasion, and her advice and opinions are listened to with oracular deference, especially if concurred in by the grandmother, if present, and the other matronly ladies who have been summoned as helpers in the emergency.

Hence it often happens that an infant child is subjected to a warm bath instead of being cleansed, as it should be, with cold water, except in very cold weather, and then it should barely be tepid; and next it is washed with rum, applied to its head, and sometimes to its entire body, by which its brain is intoxicated, and its outcries silenced by sleep, thus artificially induced by the outward application of some form of alcohol, within an hour of its birth. Next a spoon is thrust into its mouth with molasses and water, catnip tea, or, perhaps, salt and water, and some one of these doses forced into its stomach. Scarcely is the child dressed before spoon victuals are often in readiness, and on the least sign of wakefulness it must be fed, and if it cry under this savage handling, gin is added to the victuals until vomiting stops the process. Now it is pronounced to have the colic, and soot tea is thrust down its throat, and sometimes rue juice, or some other domestic remedy, to which Godfrey's cordial, Dalby's carminative, or some other anodyne is often added. Before the infant is a day old, and often before its lips have been allowed to approach the nipple of the mother, in addition to all this feeding and dosing, some *simple* medicine is given by the nurse, such as sweet oil, castor oil, magnesia, and often rhubarb, with the view of opening the bowels. Thus the child is often sickened nigh unto death, and then, when placed to the breast, the stomach is so nauseated that it loathes even nature's nutriment, and rejects even this when forced down with a spoon. Now the child is often fed again with spoon victuals, when it becomes thus early a victim of colic or griping, and the troubles of the mother with her breasts begin, which are often most afflictive and disastrous to her future health. Thus, the laws of nature being violated by the officiousness of ignorance and quackery, both mother and child suffer unnecessary and often untold mischiefs. Healthy children at birth are often sacrificed as victims to this shocking mismanagement, which is one among the prominent sources of infant mortality.

Instead of all this absurd and mischievous practice, new-born children should be placed within the folds of suitable clothing, and the light excluded from their eyes for half an hour after birth. They should then be cleansed with cold water, employing sweet oil as an auxiliary, if necessary. So soon as they are dressed they should be placed to the mother's breast, again and again, whether or not there be any secretion of milk, for their suction will soon invite it. The earliest secretion from the nipple is the only food or physic which should be allowed to enter the infant's stomach, nor should a spoon or its contents be ever placed in an infant's mouth. If mother and child are in health, the milk from the breast is the only food, drink, or medicine which will be called for during the first few months of infantile life, nor should such children be "fed" with aught else until they cut their teeth. The process of "teething" would then no longer be, as now, the fruitful source of those diseases which accompany its interruption, the chief of which may be ascribed to the feeding and physicking, rather than to the teeth. Children kept to the breast, and who have never had a spoon in their mouths, will cut their teeth without seriously suffering by the process, if previously healthy; but under the popular methods of feeding and dosing, the natural laws are perverted by impairing the general health, and hence the catalogue of diseases which are thus engendered.

Another equally prolific source of disease in children is found in the employment of anodynes by the nurse, often for the purpose of herself enjoying undisturbed rest, when from any cause the child is addicted to crying. For this purpose, paregoric or laudanum are often used, or, when these are prohibited, some vile compound of molasses and water with opium is substituted; as Godfrey's cordial, Dalby's carminative, American soothing sirup, or sleeping drops, all of which owe their effects to the opium in their composition. The effect of either of these is to produce costiveness, and pain in the bowels, which renders it necessary to repeat the use of purgatives almost every day. Is it wonderful that, under such constant medication, children should suffer from dangerous and fatal diseases? That this is another reason of the infant mortality so much deplored cannot be doubted.

It is true that feeble and sickly children from birth, or those especially who are from any cause obliged to be brought up by hand, are often of necessity sustained by the spoon or the bottle, and, if constitutionally defective, may also require medication. But very young children may have their bowels relieved by introducing a suppository of twisted paper, or a pencil of hard soap, in the way known to every nurse; and when something more active is required, a simple solution of manna may be given, which, indeed, is the only medicine called for, under ordinary circumstances, in young infants; nor can any more active article be used in such without hazard. Indeed, very many children are annually made the victims of medication, health being overthrown and life forfeited by this officious meddling of nurses and doctors.]

Sect. III.—Diet and Regimen.

Subsect. 1.—*Food allowed during Infancy and Childhood.*

6930. *The food of children*, in regard to its kind and quantity, must now come under consideration; and it is a subject of the greatest importance; for, although in subsequent periods of life health may continue unimpaired under deviations from the strictly wholesome diet—may be preserved in one case under too good living, in another by equal abstinence—may with impunity undergo any irregularity in regard to food which pleasure, convenience, or necessity may cause—yet in early infancy and during childhood such deviations and irregularities would be often fatal to life, and generally are injurious to the vigour of the digestive organs. The younger the child, the more urgent it is to take care that it has, at stated times, the food "convenient for it," but no more. To err in this respect, in the infant's case, is to run the greatest of risks in its rearing; and in regard to children of older growth, if not equally hazardous, it is often the cause to them of great suffering and of retarded growth.

6931. *Wet Nursing.*—The infant's food—that which nature provides for it immediately on its entrance into existence—must come first under consideration. When a mother has the power of suckling her infant, there can be no question that it is equally beneficial to her and her child. Only in particular cases, where some constitutional disease is apparent in the mother, can the abstaining from suckling be allowable; and this a medical man only can point out. In the act of sucking there are, to an infant, important effects. The mechanical action of the muscles employed in sucking—the labouring for food, as it has been called—is always regarded as causing most beneficial exertions in the infant, such as no other mode of taking its food can induce in it. In the act of sucking, the saliva, important to the process of digestion, is carried with the food into the stomach. The mere swallowing of food, given by the spoon to the infant, has not the same effect. The nutriment drawn by sucking from its source, and conveyed to the stomach, is of the very lightest nature; so much so that, if an infant take more at one meal than it requires, the milk instantly and easily, without pain or suffering, returns from the stomach, and the infant obtains immediate relief from the excess it had unconsciously committed—a relief rarely occurring when an infant's stomach is surcharged with other kind of food. Then the infant must undergo all the ills of indigestion, which, in its feeble state, are always serious, and often alarming. These ills of themselves afford a strong argument in favour of mothers suckling their children; or, if they cannot do it, the assistance of a healthy substitute should be procured. This first provision of nature for infancy nourishes it—as no other food has ever been found to do—*with certainty.* Every other food must always be given with the risk of its disagreeing. One kind may be too thick, and overload the stomach; another too meager, and deficient in yielding nutriment. Some kinds create acidity and flatulence; some relax, others constipate the infant's bowels; but, nourished by its mother's milk, such disturbances rarely occur, or, if occurring, are comparatively slight.

A thriving, happy infant is generally found to be the nursling of a healthy mother or nurse. To a hired substitute many mothers object; but do they object upon any very sound reasons? A careful selection should be made: the health of the individual about to be engaged for this purpose should be ascertained by medical investigation; the age of the milk, and its state, examined. To be thin and blue in appearance, sweet in taste, and abundant in quantity, are the best symptoms of good parent milk. When thick and yellow, its qualities may be suspected; and often it is, with such appearances, deficient in quantity. If the milk of a wet nurse does not suit a child, or is insufficient in quantity, the child ceases to thrive; its bowels become affected, and the skin of its neck and chest hangs loosely upon its little neck and limbs. These marks show something wrong in the suckling of the infant; they should have timely notice, and, if they continue, the nurse should be changed.

6932. During the first two months the baby should be frequently suckled; that is, as often as it seems to demand it; for, as it usually falls asleep while sucking, and, at first, often before it has had any sufficient quantity, it would be prejudicial to its thriving to attempt any great regularity in giving it its meals. When two or three months old, it will begin to take more of its nourishment at once; and then a more regular system may be, and ought to be, acted upon. At three months the intervals between its meals may usually extend to four hours; and during the nights these should be much longer—five or six hours. Its last meal at night should be given as late as possible; and then it should not have the breast again till early in the morning. We are speaking of a child of three or four months old—not younger. At night *excess of nursing* is injurious to both the mother (or nurse) and the child. A child suckled often during the night is sure to awaken often, and to require it more and more, until the nurse becomes exhausted in strength and unable to continue to suckle, and the infant also suffers. One meal succeeding another too closely, the coats of the infant's stomach become weakened and its bowels disordered.

6933. *Irregularity* in suckling is to be carefully avoided, as an infant gains strength to take a sufficient meal at one time. Proper hours for its meals should be fixed and observed: it is cruel to make the infant wait long beyond these periods; and hence mothers who cannot give up visiting while they are nurses had better relinquish this duty themselves, and in favour of a hired wet nurse, who must devote herself entirely to it.

6934. An infant should never be suckled immediately after it has been crying violently. Its agitation should be allowed to subside; or, if continued, it may proceed from pain in some part of its body, and this should be discovered before the breast is given to it. If in pain, it will be of no use to suckle it; it may, indeed, only increase its suffering.

When the mother has been, from any cause, agitated, she must avoid for a time suckling her child, or she may cause its bowels to be affected by the heat of her milk, and convulsions ensue. The same rule must be observed in regard to violent exercise; a mother must always avoid nursing her child while she is overheated by any excess of bodily exertion. The milk, like the blood, is equally affected by the emotions of the mind and the exertions of the body. At the same time, it may be here remarked, that regular and brisk exercise is always good for the mother who suckles, as well as for the child suckled; while violent exertions disturb and impair temporarily the qualities of the milk, activity renews it in quantity and improves it in quality.

6935. Every time an infant has been suckled, a cambric handkerchief or soft rag should be wrapped round the mother or nurse's finger, and the mouth and lips of the child should be gently wiped. The milk, if it remains in the mouth, soon becomes acid, and in this state causes a tendency to thrush.

6936. For the first four or five weeks an infant should have no food but that from the breast. If it be possible for the mother to continue the sole supplier of its nourishment, so much the happier for the infant; but where this cannot be done, other food must be allowed, the kinds of which usually given to infants will be found mentioned under the head "Dry Nursing."

6937. *Weaning and Dry Nursing.*—The period of weaning suckled children must depend on circumstances. Six months we should regard as the shortest time for suckling them—nine months the longest needful, unless there be, in any peculiar case, such delicacy of constitution as may render it desirable that the suckling should be continued to the end of the first year of a child's life; beyond this time we have never seen much good in suckling children, but the reverse. They are then arrived at an age in which they begin to require more substantial nutriment.

The use of the sucking bottle (see "Nursery Furniture," Book V., Chap. XIV.), if infants have been fed with it during the period of their suckling, should be continued for a short time after the weaning is begun. In no case would we recommend any sudden means of weaning; any sudden change of diet is trying to an adult, but it is hazardous to a delicate infant. A month at least should be given to the change; during which period every week should be begun with a diminution of the nourishment afforded by the mother or wet nurse, and a proportioned increase of the substituted food.

6938. *Cow's milk* does not always appear to agree at first with a suckled infant; when it does agree, no food can be better for children immediately upon weaning. By adding a little tepid water, in the proportion of one third water to three of *new* milk, this beverage might be often given with the best effect to children during their weaning. Whatever food they take should be very thin. To secure this important point, the sucking bottle is the best means, as before observed, by which weaned children should, in the first instance, receive their food. Care must be taken to keep it extremely clean, as well as the leather bag by which the baby sucks in the food. Whenever the bottle has been used, it should, after being washed, be suffered to remain in a basin of clean cold water till it is again wanted; the food of children, being either of milk, or mixed with milk, becomes so rapidly sour, if any be left in the bottle or in vessels employed in preparing and warming it, that too much stress cannot be laid on this one point of cleanliness. Sour food cannot fail to disorder the stomach and bowels of children.

6939. Children can hardly be fed too slowly, whether with the boat or the spoon; the former is now rarely used; it is more objectionable than the spoon, admitting as it does of the food being poured down an infant's throat, rather than drawn in by the child's own efforts. The boat is in form like the old-fashioned butter-boat, and was adopted as a means of avoiding the irritation to which a weaning child would give way (being used to sucking) on the spoon being withdrawn from its mouth to be refilled. But this imitation is better than *drenching* the infant, as it may be considered, with the boat. The effects of a large quantity of food suddenly entering the stomach by the boat or by any other means are seen in the child's oppressed breathing, and sometimes in more serious symptoms.

6940. *The kinds of food* to be given to weaning or dry-nursed children should be of the simplest description: of cow's milk we have already spoken: *arrow-root* and milk; *pearl sago* boiled in water till perfectly soft, and thinned with new milk; *rusks; biscuit powder; flour* previously boiled like a pudding in a basin till it is formed into a hard ball, from which portions can be grated into milk, and boiled in it till it thickens the milk, are the chief ingredients used as food for children either dry nursed from birth or weaned from suckling.

Rice gruel, barley and groat gruels, are also used in some cases, and with advantage; and as a change in the diet of children is advisable when they are occasionally indisposed, these kinds of gruel may be found useful varieties in the food of children.

6941. *Food* which contains milk should never be warmed over and over again, as is sometimes done; nor should it be suffered to remain, when cold, in metal utensils; if intended for future use, it should be put into earthen-ware basins, and set in a cool place; but no food thus set by for another day should have milk put into it; this should be added after portions of the food are separately warmed, previous to any of the child's meals.

6942. Of the consistence of food, it is necessary to observe that none should be given for the first three or four months in the life of a dry-nursed child, nor immediately to one being weaned, of scarcely greater thickness than the mother's milk. The great difficulty in observing this important rule is with nurses, who, regarding children as half starved if fed on food sufficiently thin, often counteract any wishes or commands mothers may express on this subject. They pretend children will not eat unless *they feel* the food on their lips, and they threaten the parents with all the ills of starvation if the children are to be so fed. Inexperienced and alarmed, many a young mother has yielded the point, and left the digestive powers of her child under the management of an ignorant and obstinate woman, until it has been needful to call in medical advice, and to threaten dismissal of the nurse upon her future disobedience to orders laid down.

6943. *The proper warmth* of food is also of great consequence to a fed infant; if it be given constantly hotter than the mother's milk, it is very likely to bring on that painful disease, the thrush—a disease more common and fatal to the fed than to the suckled child, owing, it is supposed, to the variation and uncertainty in the temperature of the food given to the dry-nursed.

6944. *In dry nursing* from the birth even more attention must be given to the above suggestions in regard to the use of the bottle, and to the degree of consistency and warmth of the food given to infants not suckled, inasmuch as the difficulty and risk are greater in rearing the dry-nursed child to health and vigour than the suckled infant. Its food should, in all respects, be made as similar as possible to the nourishment appointed for it by nature. In analyzing the human milk, it is found to contain some properties rather different from the milk of cows; yet it is probable that no substitute for the mother's milk can be found, in all respects, better than that of cow's milk; at first diluted, but, in the end, given as it comes fresh from the cow. Like the parent's milk, the properties of cow's milk are every day the same, or nearly so, while every other food is liable to many variations, arising from the uncertainty attending the preparation of it.

6945. *A dry-nursed child, brought up on cow's milk*, may require a change of diet rather sooner than would otherwise be thought of. On attaining its fourth or fifth month, one meal each day of more consistency may be given in moderate quantity by the spoon. At six months old, a light bread or flour pudding, consisting of bread crumbs (or one tea-spoonful of flour), the yolk of one egg, of milk as much as will fill a small basin; these, beaten well together and boiled in a small basin for ten minutes or a quarter of an hour, and, when turned out of the basin, sweetened with a little sugar, will generally be found palatable to a child of this age, and a safe gradation from its earliest food to one of more solidity. At nine or ten months old, meat panadas may be given; a few months subsequently, meat, merely minced, with mashed potatoes, or well-boiled cauliflower or brocoli. No one meal should consist of many things; meat and vegetables, without pudding, or pudding without meat, we would advise to be given on alternate days, till the child is a year and a half old.

6946. *The nutriment of children*, after the completion of their first year and a half, it will be necessary to increase in solidity, and, if their appetite seems to demand it, in quantity also. Their teeth begin now to aid them in masticating food, their limbs become firmer, and carry their bodily exertions often to a great extent; it is scarcely calculable the degree of exercise which healthy children voluntarily give themselves, but which stimulates the digestive organs, enabling them to receive and act upon more solid nutriment than heretofore given them. Having previously had animal food three or four times a week, children may, in the second year of their lives, safely eat it once every day—meats being chosen for them that are tender and nutritious. *Roast beef; mutton*, either boiled, roasted, or broiled; *chickens*; some kinds of *fish*; well-boiled *vegetables*, such as *brocoli, turnips, potatoes* (the latter are best for them when mashed with hot milk and a little salt); simple compounds of egg and milk; *fruits*, baked or boiled; *bread*, well made and well baked, with small portions of *butter*; these, with milk for breakfast and supper, with water as beverage, are the chief articles of wholesome food for children as long as they continue under nursery management.

6947. *The species of food we would not give them consists* of salted meats (beef, pork, or bacon); of rich stews, ragouts, and soups; of fried fish; of pastry and confectionery generally; of cheese; and of beverage, tea, coffee, beer, and wine. Of the two last mentioned, beer and wine, we may remark that, in cases of delicate health, they may be advantageously allowed; but they should always be given under medical direction, for the stimulus of fermented or spirituous liquids is not in every case of debility beneficial, sometimes the reverse; neither ought children to be allowed to drink much at a time of any liquid, however mild and innocent it may be. Too much liquid has a tendency to create flatulency, and to distend the bowels. It has been said that parents accustoming their children to drink water only, bestow a fortune upon them of the value of which they will be sensible all the days of their life.

6948. *The habits of children* at their meals should be attended to. We would let them use the spoon or fork early. It is keeping them too childish to feed them after they have strength enough to hold the spoon. At first the nurse or mother should superintend the child's attempts to feed itself; should place the spoon in its right hand; see that it is not filled too full, nor, when lifted to the mouth, forced awkwardly into it. The child should be prevented, when he seems to have satisfied his appetite, from throwing about the remains of his food, by his plate being removed to a sufficient distance from him, and his spoon taken gently out of his hand. This being uniformly done when he is inclined to scatter his food around him, will soon cure him of the trick. The use of a knife cannot, at this early period, be allowed him; he must not have it until he has sense to know the danger of misapplying it.

Children's meat should be minced as small as possible. If too much trouble is left to their feeble power of masticating, they will shun it by swallowing their food unmasticated. For children whose digestion is weak, it may even be desirable to have their meat pounded.

6949. *Children* should be encouraged to sit still at their meals; but these should be made as short as possible, that the patience of the children may not be tried too severely. Also, they should be encouraged in cheerfulness at meal time, and not in turbulence. Vigour in the digestive organs is said to be promoted by cheerfulness, but impaired by gloomy impressions, or by great anxiety of mind indulged in during meals. If this be the case, it must be desirable to keep children's spirits free from any depressing influences, and yet not forced into the opposite extreme of excitement.

6950. *In childhood, as with most young animals, activity after eating seems natural*, and we may thence infer that it is beneficial also, although in later seasons of life the reverse appears to be more generally believed. If, however, children are inclined to active sports after their meals, it is wisest to allow them, otherwise they will be fretful in their obedience, or altogether rebellious.

6951. *Greediness* is a disagreeable habit in children, too often encouraged by fruit, cakes, or other sweet things being given them as rewards, or withheld from them as punishments, and thus is an undeserved value placed on such things. Sometimes, if begged for with childish importunity or petulance, they are given to silence the bold beggar. The more timid child gains nothing by his opposite conduct, except, perhaps, to see justice and impartiality sacrificed to loud vociferations and tears. When children are really deserving of punishment, it is not a desirable way of inflicting it by any deprivation of food or dainties; certainly not to give to the brother or sister the portion forfeited by the offending party. Anger, on the one hand, is probably excited towards the favoured one, and pleasure, on the other hand, by the mortification experienced by the offending brother or sister. If any use in education be made of the natural love of sweet things, it should be to cement the social and relative connexions in life, not to dissever *them*; also, to discourage selfishness, and to forward the development of the generous and disinterested qualities. These moral benefits may be looked for when children are taught to sacrifice all enjoyments which end in self, to the higher pleasure of imparting enjoyment to others. To induce children to share with or give to brothers and sisters the things they like themselves, is the best use that can be made of the love of sweet things and dainties.

Greediness would be scarcely known in children if none but simple, wholesome food were placed before them. Such rarely tempts to immoderate indulgence of the appetite, but renders restriction almost needless. Tempt children with dainties, and restriction becomes needful, yet it does but increase the value of the things desired. Compulsory regulation of the appetite does not induce that most important of habits, self-restraint. The reverse is often more obvious. Those children whose appetites are strictly regulated by vigilant mothers and nurses more frequently transgress, when opportunity allows them, the rule of moderation than those do whose unpampered appetites are left to their own discretion. An infant almost uniformly expresses its satisfied appetite by pushing away the offered spoon, or by receiving its contents with indifference, that decided symptom of satiety which ought never to be unnoticed; no child, after such show of indifference to its food, should be urged to eat, even though it may not have cleared the plate or basin of its contents. It is safer to waste such remnants than to surcharge the organ of digestion. It is equally injurious to the child, whether the nurse forces it to take more food than it requires, or whether its own pampered taste induces greediness. Yet many nursery disciplinarians think it their duty to force children to eat up all that has been put upon their plates, forgetting how much they themselves might suffer from indigestion were they compelled to similar excess in eating. Neither is the subject of antipathies to particular articles of food always sufficiently considered. It is sometimes thought necessary to overcome them by forcing the child to eat what seems to be so very repugnant to it. Nature prescribes a different rule; what is thus disliked by any individual is often peculiarly injurious to that individual. Thus, in regard to the fat of butcher's meat; wherever it is much disliked we may believe that it is not only unpalatable, but prejudicial, and not to be forced upon any one. This aversion should not be regarded as caprice, but as arising from some peculiar state of the stomach that time or change may rectify, but not compulsion.

[It must be confessed that a luxurious mode of living often unfits a mother for being a nurse; and hence it is common among the wealthy, in imitation of her majesty, Queen Victoria, to substitute the breasts of a wet nurse for those of the mother. Nevertheless, both nature and philosophy teach, what experience confirms, that every mother should be the nurse of her own child whenever it is practicable, and this in view of her own health as well as that of her infant. Even in the case of consumptive ladies, experience amply proves that nursing will often relieve the affection of the lungs, and improve the general health. Such mothers, however emaciated, *if their appetite be good*, which is often the case, should be advised to suckle their children two or three times a day as the most likely means to restore their health. That those mothers who do not suckle their children are most subject to consumption, cancers of the breast and womb, &c., has long ago been observed: hence it has grown into an axiom that, if the mother be healthy, suckling will confirm her health; and if weakly, it will, in most cases, improve it. No other woman's milk can be so good for her own child; and as to *dry nursing*, it is unnatural and dangerous; very few of those thus brought up ever live a single year, and hence, when resorted to, it ought to be a measure of imperious necessity. When, however, a mother is unable to be the nurse of her own offspring, from disease or any other cause, or when, as is too often the case, the mother perishes in the act of giving birth to her child, in either case a wet nurse should be provided; and the choice of a woman for this service should be judiciously made. A middle-aged woman should be preferred, if she have previously borne children, for such will have more milk than the young, and more and better than the old. She should be one who has not been confined with her own infant more than three months; nor is any woman fit for a wet nurse six months after delivery, the milk being found to vary in its specific quality according to its age; and, moreover, as nature never intended a mother to nurse her child longer than twelve months, the milk will seldom continue good after that period, and hence all children ought to be weaned when they become a year old.

The nurse's food should consist of fresh meat and vegetables, bread, broth, milk, &c., without any strong liquors; and, in the absence of the first secretion of the mother's breast, which is always sufficiently purgative, the nurse should take some laxative medicine, which, through the medium of the milk, is found to operate upon the child.

As, however, children are often condemned to be brought up without the breast either of the mother or wet nurse, in such cases very different management is required, and to regulate the quality and quantity of the food becomes a subject of great importance. It is for lack of judgment in these particulars that such children suffer so much from colic and griping. It is a common mistake to suppose that whenever the child cries it wants victuals, while the acute pain and spasms, by over-distention of the stomach, is by far the more frequent cause. Indeed, healthy children seldom cry except from pain, and hunger does not cause pain unless it be very protracted. The nurse often forces down food to quiet the outcries of a child suffering already from an excess in quantity. The generation of acids and gases from the fermentation of the spoon victuals remaining undigested, by producing irritation and spasms in the stomach and bowels, gives rise to what are called inward fits, convulsions, and, not unfrequently, inflammation of the bowels. Children that are fed only four or five times in the twenty-four hours are more healthy, active, and cheerful than those who are never suffered to be hungry. Milk from the cow, goat, or ass will be the best substitute for human milk, when this is not to be had; and, in addition, potatoes, arrow-root, bread or rice flour, sago, or tapioca, and, if necessary, as the child grows older, thin and light broth, free from fat, may be superadded. Until the child cuts its teeth, however, potatoes boiled and mashed, being then mixed with fresh milk, unboiled, will be found to be preferable to most other articles, and afford ample nutriment. Children should always be fed in a sitting posture, that swallowing may be more easy to them; and if the child be not accustomed to night feeding, it will not become over-fat and bloated, but will contract the habit of sleeping the greater part of the night. When the bowels become irritable, from acid or flatulence, the best corrective is limewater, a spoonful or two being added to the food, with a little essence of peppermint or anise seed. The custom of giving spirits of any kind in children's food cannot be too highly reprobated. Strong liquors of all kinds should be avoided; and, though some children have been known to thrive under their use, it is only when the vigour of their constitution has been sufficient to counteract their usual pernicious effects.

But none of these instructions for feeding children are called for where the mother survives, and can, by possibility, perform the duty of nurse to her offspring. If the nipples be short, they may be drawn out by the nurse, or by some form of nipple-glass; and this is often needful in young mothers. When they are tender, they should be washed with brandy or a solution of borax: the poisonous preparations of lead used by nurses and recommended by quacks are high mischievous. If the nipples be small, tender, and ulcerated, there are various contrivances to enable her still to suckle her infant, the best of which is the prepared nipple, or the teats of calves, which will be found well adapted to the purpose. And for washing ulcerated nipples, a solution in water of the seeds of quinces, or some similar bland mucilage, will be found most useful.

Inflammation of the breast is another frequent obstacle to nursing by which young mothers are afflicted. Leeches early applied to the part, and some spirituous lotion, with a free purgative, will often prevent the formation of matter. Where these fail, however, and an abscess forms, it should be opened early and freely, after which a linseed poultice may be used until the matter is all discharged, when the adjacent skin may be washed with brandy two or three times a day, and dry lint applied until it heals. All oily liniments and ointments are hurtful.]

Subsect. 2.—*Sleep of Children.*

6952. "*Infants can scarcely sleep* too long at a time" for the first four or five months of their existence. During this period it is natural to them to spend their chief time in sleep. A merciful provision this, in the most helpless portion of infancy's existence; and for these reasons, while an infant's body is in a horizontal position and during sleep, the circulation of the blood proceeds more equably and calmly, the respiration is more easy, the function of digestion more steady and effective, the nutrition resulting from its processes more perfect than when the infant is in an upright position. Thus this tendency to repose is a protection against infancy's own feebleness, which might render every casualty that presented itself a real danger, an obstacle to the healthy operations of its delicate functions. The calm, steady sleep of an infant for three or four hours at a time is the mother's warrant that all is going on well with it. Were it otherwise, its rest would be broken, its crying frequent, and its bodily development and vigour would be evidently retarded and imperfect. It has been said by a German medical writer of the last century, Professor Hufeland, that twenty-four hours of perpetual *watchfulness* would be sufficient to destroy an infant of two months old. Whether this notion be well or ill founded, it conveys to us his conviction of the importance and value of long and undisturbed sleep at the earliest period of human existence.

6953. For the first three or four months of infancy any strict regulation as to habits of sleeping can scarcely be observed, no more than with regard to the meal time of infants.

6954. By the time they attain their third month some steps may be taken towards the regulation of these infantile habits. For instance, young infants often begin their lives in sleeping more by day than in the night, a very troublesome and inconvenient habit, but which it is difficult to alter; yet as soon as an infant begins to take notice, his nurse should endeavour to keep him lively and awake as the evenings draw in, by rousing his attention to everything around (for at this period his observations will be commencing their operations), and by nursing him actively in her arms. Thus, by slight fatigue and longer wakefulness, she will be preparing him so settle early in the evening. As soon as possible, suckling or feeding a child at night should be discontinued, as before remarked. Sleep at night will now be more salutary to the child than food. Now the inclination for food at night should be repressed, and the habits of sleeping equally encouraged.

6955. From its birth to the age of five or six months an infant should have two sleeps in the day, one in the fore, the other in the afternoon, each of an hour's length, if it can be obtained.

6956. At the period of the sixth month the afternoon sleep may be dispensed with; the morning sleep should be brought into midday, and should be continued till the end of the second year of a child's life, and sometimes it may be continued with advantage for a longer period.

6957. All children should rise early in the summer; there is no air so refreshing to their young nerves and muscles as the early morning air. The sun has not then given out its full heat, nor drawn upward arid, humid, or impure exhalations from the earth; it is in its best state for imparting vigour to both young and old. In the winter there are reasons for admitting of later morning hours. Children, especially very young ones, can gain little by rising in severe weather before the fires are lighted, and the air of the rooms into which they are to go is sufficiently warmed to save them the suffering which severe cold always inflicts upon them, and which is expressed by them in crying and fretfulness. Let them remain an hour longer in their warm beds, and they will show their thankfulness for the boon in their countenances and tempers. The active natures of children will always incite them to early rising as soon as their limbs are strong enough to carry on any exertion of the body sufficiently stimulating to their feeble circulation.

6958. Laziness in the morning is a bad habit of a later growth, not then to be indulged; yet still some limitation there should be in regard to the number of hours given to repose. In duration, a child's night should neither be more nor less than ten hours. When children, from habit, sleep longer than this, it may be proper to awaken them at one uniform hour, and thus destroy the wrong and establish the better habit.

6959. *But in rousing young children* the gentlest means should be employed, not violent shaking or loud speaking. It is extremely hazardous to startle or shock children when they are awake, but to rouse them from the unconsciousness of sleep into a state of terror is still more erroneous and dangerous. A boisterous, rude, or harsh nurse may in this way make an impression of horror on a child's mind that no subsequent measures of gentleness and kindness may be able to efface. Very opposite should be the mode of waking children we would prescribe. They should never, could we prevent it, open their eyes from their easy slumbers on gloomy or angry countenances. A smiling face and gentle voice should be the medium of a child's transition from the peaceful state of sleep to a cheerful, happy reality.

6960. *Sleep, to be salutary*, should be naturally procured. During dentition, or by occasional disturbances of the alimentary function, the sleep of young children is sometimes disturbed. The irritation becoming excessive, a medical man may see occasion to administer small and suitable opiates, and thereby sleep is obtained which may be absolutely requisite; but as an habitual or frequent measure, no medical man in the case of children would advise opiates to be resorted to. The immediate but transient effect of opiates on an infant is to still its nervous irritability; the subsequent consequence is to increase it as soon as the power of the opiate has passed off. When opiates are frequently given, a child's muscular vigour decreases, its countenance becomes pallid, the growth of the body is checked, the whole system is debilitated; convulsions sometimes ensue. These symptoms are here stated as warnings to mothers and nurses who, from ignorance of their danger, may be incautious in administering opiates to children; such as Dalby's carminative, the American soothing sirup, paregoric elixir, medicines which may be occasionally safely given, but not frequently without serious risk.

6961. *The best plan for getting children to sleep* is by laying them down to rest at stated hours, when, from habit, the inclination to sleep becomes the strongest. A child accustomed to be laid down awake is seldom restless or fretful, but often closes its eyes immediately on being laid down, and is asleep at once. When any deviation from this occurs, and the child, instead of composing itself, is restless, it may be inferred that something is amiss with it, that it is in pain or otherwise indisposed. Its state should be examined into, and judged of as well as it can be, before any attempt is renewed to make it fall asleep. When a child is indisposed it may be difficult to keep it in its crib, or get it to sleep in the usual mode: it must then be taken on the knee, and gently soothed to sleep by the motion of the nurse's knees; but, as a habit, this rocking to sleep is not to be encouraged: when, from the age of a child, it becomes necessary to break through it, it often proves a painful struggle to both child and nurse.

6962. *A child's position in bed* is of importance. Its pillow or bolster should be scarcely raised above the surface of the bed (see Med. Art. on the "Spine"). An infant should be laid down to sleep on its side, with its mouth and nostrils clear of the bed-clothes, as well as the whole of the face; for, while currents of air should be guarded from a child's head, there should be free admission of air to its mouth; and if infants incline to sleep better on one side than the other, the nurse, observing it, should endeavour to counter act the habit by laying it down to sleep on the alternate sides. From the day of its birth this precaution should be employed.

6963. *Infants require* warmth in their bed-clothes, and will neither sleep comfortably nor for any length of time unless it be afforded them; but the degree of warmth allowed must not be such as to cause perspiration, and which would weaken and render a child too susceptible of cold. No doubt an infant will sleep more soundly on the nurse's arm than in its own bed; and a sickly, delicate child is often comforted, nourished, and lulled by the warmth so imparted to it. The infants of the poor have always this comfort, whatever else they may want; many delicate infants in the houses of the poor would perish but for the warmth thus imparted to them during the night. For the infants of the affluent, who can envelope them in flannels and blankets, and keep them in apartments of a regulated temperature, there is less weight of argument in favour of their sleeping on the nurse's arm, and some seasons there are which render it undesirable. It frequently induces profuse perspiration in the child, and sometimes, especially when the face is covered, brings on that relaxed state of the mucous membrane which occasions the complaint called by nurses the *snuffles*, from the disagreeable noise made by the child in breathing through the nostrils.

6964. An infant lying *on* the arm of its mother or nurse is in no danger of being *overlaid;* but if, by any movement of the nurse, the child's head slips off the arm during her sleep, very distressing consequences may ensue. If her body press against and cover the mouth and nostrils of the infant, its struggles may be too feeble to rouse her from sleep, and its suffocation would then soon occur.

6965. *Children* of two or three years of age will require, if they are healthy, less bed-clothing than during their earlier infancy: their circulation is become stronger and quicker, and perspiration more easily induced in them, which, if frequent and profuse, is extremely debilitating; yet insufficient covering in cold weather would be equally prejudicial to them, and would prevent them from sleeping soundly.

Subsect. 3.—*Exercise of Infancy and Childhood.*

Exercise during infancy and childhood is the next subject of importance to which maternal attention should be given.

6966. *The muscular organs*, on which bodily activity depends, and on activity strength in the limbs and health in the functions of life, are themselves acted upon, invigorated by exercise, provided it be progressive and uniform: no overstrain upon them one day, nor disuse allowed them at other times. Either excess of exercise or the want of it would alike debilitate them. Thus, muscular power, which varies in degree in men and women, and equally so among individuals of either sex, may yet be, in each individual case, improved or impaired by exercise, according to the use or abuse of it.

6967. In this chapter, which relates to the physical treatment of infancy and childhood only, there seems no reason for prescribing different rules for the treatment of boys and girls. To the age of five or six they must be, in all material points, brought up alike. As they progress towards youth, modifications in the bodily treatment of girls will occur, in contemplation of their future position in life, which will require from them sedentary employment, and deny them indulgence in any but gentle exercise, suited to the part they have to fill in their social life.

6968. From birth to maturity, nature, by progressive, and not sudden measures, gives strength to all organized beings; hence this rule must be observed by those who conduct the physical education of infancy and childhood. Exercise proper for infancy is, at first, but the gentlest of movements in the nurse's arms, on her knee. Afterward, when three weeks or a month old, an infant may be carried out of doors, but always in a recumbent posture, for in that posture an infant should be principally kept for the first six weeks or two months of its existence.

6969. Night and morning, after being washed, the limbs, back, and stomach of an infant should be gently rubbed by the nurse. This friction may scarcely be termed exercise, but it acts as such on the delicate vessels of the skin, sending through them that degree of circulation which renews the warmth of the body, and promotes the healthy action throughout the skin, the body's covering, which it is most important to the animal economy to preserve in health.

6970. *An infant of three months old* should then begin to have active nursing in the arms. At this period a child may be permitted to be carried about in an upright position. Every nurse-maid should accustom herself to carry children on either hand; if this be done alternately, a child is in less danger of acquiring any habitual position of the body, which might end in a curvature of the spine, especially if there be in the infant any constitutional weakness. To vigorous children the mode of carrying may not be of the same consequence; but it is often very distressing to those who have maternal feelings to see fine children carried about for hours together, on the left arm generally, their bodies bent forward, their backs forming a bow; unnoticed by their nurses, their countenances are overcast, and the benefit the air and exercise might afford them is lessened by the weariness they evidently experience from this continued, painful position on the same arm. Children, after illness, being carried about in this one position, often become deformed. Besides being at this period carried, the child may be tossed in the air (though not too violently) with good effect; it may be laid on its back on the floor, or on a mattress, and suffered to kick out its legs, and to stretch out its arms, but it ought not to be kept long in any one position. The moment it begins to wail it should be taken up, and some other motion tried, to keep it lively, and its muscles in gentle play. In doing this we are acting in concert with nature, who did not give this untiring inclination to active occupation without some end. It is manifest that the progressive development of both the physical and mental powers is the object for which activity and curiosity were given to infancy and childhood; and whenever we circumscribe their range, we do but defeat nature's purposes.

6971. *An infant of six months*, if very vigorous, sometimes will begin to bend forward out of the nurse's arms, impelled by the desire to be on the ground, and on its feet. It is rather early to begin to walk, but vigour in the infant is the impelling cause, which it may not be well altogether to frustrate. If an infant be encouraged to put its feet thus early to the ground, it should at first only be allowed to do so for short intervals at a time: the nurse should endeavour to amuse her charge with other exercises as soon as she thinks he has been long enough on his feet. If she can teach him to crawl, she will give him a more beneficial mode of exercise; one which brings the muscles into easy play, and removes the weight of the head from the spine. A weakly child, however, will not attempt any permanent exertions; it will be content with the ease it enjoys in the nurse's arms. In this case, no forcing to activity should be allowed; the infant may be laid now and then on its back, and on a carpet, but unless it attempts to crawl of its own accord, it will not be wise to urge it to do so. By slower degrees the muscular action must be obtained and invigorated, probably by adopting measures to improve the infant's general health.

6972. Children are sometimes allowed to sit long, either on chairs or tables, or in little nursery swings: the pressure on the spine is then too continued, the muscles of the legs and thighs waste rather than increase, and sometimes these limbs become crooked in consequence. If children fall asleep while fastened in their chairs, their heads bend forward, and their respiration is impeded by the position of their bodies.

6973. *Children advancing to the term* of their first year will begin to exercise themselves spontaneously, and this is far more salutary than any exercise can be which is forced upon them: their own efforts will never harass or over-fatigue them; they will involuntarily relinquish them as weariness grows upon them.

6974. *Before encouraging children* to use their feet, we should look to their actual strength, not deciding how far they should be urged to walk by the actual number of months they have lived. It was not long ago considered as a reproach to a nurse if her nursling could speak before it could walk: to avert this supposed proof of bad nursing, many a child's real good has been sacrificed. Before its strength allowed, it has been urged to totter on its bending limbs, when it should rather have been reposing on the floor, or only making its own natural movements proportioned to its strength. When a child's limbs are not sufficiently strong to support the body, the consequences of urging it to walk upon them will be curved legs and weakened ankles. All artificial means of inducing children to walk, such as the go-cart and leading strings, are happily in disuse. They were, when much employed, fatal to the healthy growth of a child. If a young child once acquires the art of crawling, it will soon do more, and try to use its legs; it will first raise itself by the support of a chair or stool, will then totter from one side of it to the other, holding itself up, and by repeated exercises of this kind the limbs will acquire the requisite power, and the infant will gain courage to trust to that power; then it will walk alone. Many a fall it will have, but these will add prudence to its growing power. Let it be here observed that it is wiser, when a child has slight falls, not to run hastily to it, raise it up, or try to soothe it. Instead of going to its assistance too precipitately, it is better, if it be not really hurt, to let it help itself. This it will very soon do; and better, also, than any one can do for it. We are now alluding only to the many trifling accidents in a child's life; not to those of a serious nature, to which humanity, as well as necessity, prompts to immediate attention whenever they occur. We only recommend the discouragement of children's cries at small difficulties; aid given to these cries too promptly and too soothingly deprives children of that independence of spirit which eventually we seek to inculcate in them.

6975. However, in beginning to walk, a child must have some assistance. This should be given by holding it firmly *under*, not *by the arms*. It is frightful to see a child, held by one arm, swing its body round, in the eagerness of its exertions. Were the joints of the arms less limber than they are in childhood, such movements would nearly dislocate them.

6976. Scarcely is any sight more delightful to parents than that of the first setting off of their child; nor do *they* only feel delight; the happiness of the child, to all appearance, exceeds their own; when first it is conscious of its independence, its state of ecstasy is almost enviable. Arrived at this happy epoch in its life, something farther is yet to be done to give the child greater steadiness, and greater freedom of step and carriage. For this end *long walks* must be avoided. Children from a year and a half to two years old should scarcely even walk more than a quarter of an hour at a time; if longer, the muscles of the legs will be weakened rather than strengthened, and the child's step will be unequal and unsteady, and its carriage awkward and waddling: were it possible, a child for the first three years of its life should rarely take a walk, but rather be turned into a garden, be it ever so small; there it can run, stop, walk slowly or fast, can stoop down to pick up pebbles or flowers, then rise up; in each movement different sets of muscles are employed, one set being the safeguard to another of any overstrain upon it, by coming into play according to its rise in different postures and movements of the body. In walking at a uniform rate, in streets or on roads, one set of muscles are chiefly used, which soon tire, and give feelings of lassitude to the child it would never have experienced in the more varied change of the garden.

6977. *As children grow older and stronger*, athletic sports may be introduced among them, equally advantageous to girls as to boys, such as games at ball of various kinds, of battledore and shuttlecock, whipping tops, prisoners' base, tennis ball, and hooping, with other running games. Such sports as these will bring into healthy action the whole muscular system. The skipping rope gives excellent exercise to older children. The running and racing games should not be encouraged when children have coughs, or show any symptoms of diseased lungs. In such cases, the rapid urging of the blood into the lungs, caused by the exercise, would be very prejudicial, and might bring on inflammation of the lungs. And the same caution will apply to children troubled with temporary bowel complaints. Children with delicate bowels should never be allowed to take long walks, and violently active sports they should indulge in very moderately.

6978. In all ordinary cases of children, outdoor amusements are the best. The only precaution needful is with delicate or diseased children, in whom exercise should be as regular, but not in degree the same, as with the healthy. There are but few children who would not be the better for constant outdoor exercise, were it properly proportioned to their strength and years. When town children are taken for health to the coast, they are often made ill by the immediate injudicious degree to which their outdoor exercises are allowed to extend, while those who are under more prudent direction in this respect often derive the utmost benefit from the more measured enjoyment of their absence from towns and cities. It has been remarked that, among all the public institutions of European cities, none have provided for the innocent pleasures of children. In cities where private gardens, if there be any, can only be secured to the affluent, how beneficial would be, to the humbler classes, airy grounds, into which their children might be turned, safe from all the hazards and accidents of the streets, their only play-ground. Such would, indeed, be pleasure-grounds, and would conduce more to the welfare of rising generations than even the infant schools.

6979. It may be said that children would soon be tired of such play-grounds. The enjoyment seen among the flocks of children resorting to the open parts of the Regent's Park during the greater part of the year contradicts this objection; were such places multiplied round the town, and free access allowed to children, disease would find fewer victims among the poor than at present is the case.

[Children should be early trained to exercise their limbs, and, if healthy, they should be taught to walk by the time they are a year old. Weakly children, and even those whose legs are bent or crooked, may be essentially benefited, and their limbs made strong and straight, by frequent walking; and it is a vulgar as well as pernicious error to allow of the disuse of their limbs from a groundless apprehension of any possible injury by exercise.

So soon as children are able to walk, they should be trained to bear exercise without fatigue, by gradually increasing the length of their walk, until, by the time they are three years old, they are able to go two miles without weariness: thus, a dull, heavy child may be made playful and sprightly, and a weakly one healthy and strong, by regular habits of exercise. The cold plunging or shower bath is a valuable additional exercise for delicate children, which, during warm weather, should be repeated every morning.

Cradles are often relied on to give exercise to children by rocking—a barbarous and mischievous error; for the effect of rocking is to produce vertigo, and a species of intoxication of the brain of the child, which, being often repeated, predisposes to diseases of the head.

When children are old enough to take exercise upon a rocking-horse, this will be uniformly salutary. Swinging the dumb-bells, though often recommended, will produce deformity in some cases, and hence jumping the rope is to be preferred, especially for female children; but, after all, when, under the impulse of their own active vigour, they are impelled to running, leaping, and other sports of agility, these will be found better than any modes of exercise which may be prescribed merely for health.]

SUBSECT. 4.—*Clothing of Infants and Children.*

6980. *The clothing of infants should be warm, light, and loose.* Warm clothing is essential to infants during the early period of their existence, in which their organs and functions are so feeble that any excess of cold would quickly destroy the vital principle within them. Life in infancy is, more than at any other period, at the mercy of external influences. Sudden transitions from warm to cold check, in an infant, the circulation previously going on on the surface of the body, and drives the blood internally, so hastily as to cause some immediate evil, which would come under the general term "inflammation." Either the bowels, lungs, windpipe, or head may be attacked; hence, in the choice of an infant's clothing, that kind should be employed which may seem best adapted to secure the equal and tranquil diffusion of the blood throughout the system. Although sufficiently warm, it should be also light. If overloaded with its dress, especially in apartments in which the temperature is high, profuse perspiration may be induced in an infant, a state which is as carefully to be avoided as that caused by extreme cold. Frequent and copious perspirations impoverish the blood and enfeeble the internal organs.

6981. *By warm clothing is meant* the use of such materials and textures as best retain, when in use, the heat imparted to them by the body; such materials are called *non-conductors* of heat, and consist of flannels, woollen fabrics, and furs. In these heat accumulates, and is recommunicated to the body of the wearer.

6982. *Cool clothing*, such as *linen*, conducts heat; and even to a certain degree *muslin* and *cotton* are conductors of heat: the warmth they receive they as easily part with, and it is carried off into the atmosphere.

6983. *Flannel* worn next the skin acts upon it like a gentle flesh-brush, warming the surface and stimulating the nerves and fine vessels of the skin; soft and light, as well as of a warming quality. Flannel cannot, in this country at least, be dispensed with as an article of infant clothing. Most of the infant's under garments are of this material, although immediately next the chest and arms a fine linen or cambric shirt is worn. Above the flannel is a light petticoat of muslin, and above this a loose dress with long sleeves, and made to draw tight on the chest. As it is not well to fatigue a young infant with needless change of clothes, the dress above mentioned is, for the first fortnight or three weeks, seldom changed more than once in twenty-four hours. At the end of a month or six weeks the infant is strong enough generally to be dressed and undressed morning and night, when a difference is made between the day and night clothing; in the latter a sort of flannel wrapper is worn instead of a flannel petticoat.

6984. *Infants, for the first three or four months, are clothed in very long petticoats.* There is some utility in having the clothes of very young children of a considerable length; they help to keep the extremities of the infant safe from cold air, which would otherwise chill an infant very severely; and long clothes do also give a nurse a good hold of a child, who, without sufficient clothing, would be apt to slip out of the arms; but to have them so long as to trail on the ground, or to float with every move made by the nurse, so as to reach the bars of the grate, is preposterous, and even dangerous, and the good sense of mothers ought to be exerted to lay aside this worthless fashion, and adopt a more moderate manner in this respect. The only really essential points in infant clothing are warmth, simplicity, ease, and cleanliness.

6985. *Ease* ought never to be sacrificed to appearance; no dress that is made so as to compress or bind the person of an infant should be allowed; the use of all bandages, swaddling-clothes, tight ligatures, is most carefully to be forbidden. Every article of an infant's dress should be made as loose and easy as if it could, if needful, be made to slip off the shoulders. Too much stress cannot be laid on this subject. Tight bandaging, tight lacing, or any compression in the dress of children, if continued, injure the respiration and the action of the heart; the spine also often becomes turned by inducing children to put themselves into the posture in which they find most relief, and from the pain arising from any tight ligatures. There should be nothing in the dress of children that can restrain the free movement of all their limbs and muscles. To boys, tight waistcoats and bands are very seriously injurious, causing in them undue pressure upon other and very delicate parts of the body. In regard to the stays of girls, worn in after life, every medical man can explain to mothers the main grounds of objection to them; and no sensible or affectionate mother but would immediately make war with fashion rather than consign her young children to the sorrows and calamities of ill health.

6986. *To keep the head cool and the feet warm* may be a modern axiom, but is a good one. Caps, it is well known, are not an essential in the dress of a young infant. If born with hair, the infant can very well spare the artificial covering usually provided for it. If a cap be not worn by day, neither should one be worn during the night. This plan of dispensing with the use of caps it is very desirable to adopt, if there be in young children any tendency to water on the brain. For the same reason, heavy beaver hats and velvet bonnets, graced with plumes of feathers are the worst coverings for a child's head that can be selected. While the mother is admiring the face and curly hair beneath the heavy hat or bonnet, she is not conscious that the heat and the weight are acting forcibly and prejudicially on the delicate vessels of the head, often causing headache, if not tendencies to severe diseases. The age of the child denies him the power of expressing his suffering except by fretfulness, which alike surprises and vexes the poor mother. A lighter covering of the head might remove this annoyance.

6987. *The feet of children* should be kept warm and dry. A young infant should, in the winter, wear soft woollen socks; and children of all ages should, in this climate, wear woollen socks during three parts of the year.

A different notion and practice were formerly adopted in regard to children. They were seldom seen in socks or stockings; and even some writers on education, Locke for instance, recommend that children should have leaky shoes rather than such as would exclude the wet, as the best means of hardening and inuring them to the changeable climate in which they were born. Modern opinion and practice are the reverse of this; and the consequence is, that more children are reared now than were under the former mode of treatment: then the healthy children only survived; the delicate sunk under the hardening system. To keep the feet dry and warm of infants and children generally is the uniform advice of all medical men of the present day, and also of all persons whose observation has been principally exercised, and their experience gained, in the management of young children.

6988. *Tight shoes*, next to tight lacing, are among the domestic tortures that might generally be spared young children. It is not so much small shoes as ill-made shoes that produce injury to young feet. Shoes that do not fit well are soon worn down at the heel; a child's ankle seems to give way also, and to bend towards the defective part of the shoe; and its step becomes thus, with the use of ill-made shoes, both unsafe and awkward. To avoid this inconvenience, many mothers have boots made for their children; but to wear these constantly has its ill effects also. The ankles become accustomed to the support of the boot, and, when left off, the child appears to have weak ankles, and to be easily fatigued when walking without the support of his boots. Some persons advise for children the use of heavy shoes, as strengthening to the muscles of the ankles. If proper attention could be given by parents to this subject, and the weight of the shoe very properly adapted to the strength of a child's ankle, it might not be an unsuccessful means of adding to the muscular power of children; but when we consider that the strongest in limb among the Irish and Scotch are those who go entirely without shoes and stockings, the importance attached to the wearing a heavy shoe as a means of strengthening the ankles diminishes. To prevent children from sitting or standing long in wet shoes is a much more necessary precaution.

6989. The evaporation constantly going on, from the moisture of the shoe and from the warmth of the foot, withdraws so much warmth from the circulation as is extremely weakening, and especially to children of delicate constitutions. Chilliness is the immediate consequence, often succeeded by inflammatory attacks either of the lungs, throat, or bowels. It is, perhaps, needless to add that children, as a rule, whether the weather be dry or moist, should always change their shoes when they return from outdoor exercise, and are going to remain for some time in the house. Those who have the charge of children's shoes should always attend to their being well dried after they have been used in wet weather.

[A new-born infant is naturally warmer than an adult, and should, therefore, be less burdened with clothing; and this should be *loose*, so that no considerable pressure may be made upon the bowels or upon the limbs. This free motion of the body, and the absence of all compression, are necessary for comfort and health, so that the circulation in the superficial vessels may not be hindered. Malformations and unnatural swellings are often produced by *partial* compression, particularly in female or delicate children, resulting in distortions and deformities, as a consequence of tight clothing. The greater or less amount of clothing should be proportioned to the climate and season. In general, however, all that will be required will be a flannel waistcoat without sleeves, made to fit the body and tie loosely behind, with a petticoat not quite so long as the child, and a frock over this, a little longer, both of some light, thin material, and loosely secured to the body, avoiding any pressure which shall confine the motion of the ribs. All swathes, bandages, and stays are mischievous, and should be prohibited. If any covering for the head is insisted upon, it should be only a thin cap; but it would be far better if the practice of putting caps on young infants were utterly abandoned, as it is by judicious nurses. The friction of the cap wears off the hair, and, besides keeping the head warm, it proves a source of irritation which often results in eruptions upon the scalp and behind the ears, which are seldom or never met with in children who have never worn caps by day or night, in winter or summer. Indeed, there is good reason to believe that a predisposition to head complaints is very often produced by wearing caps, and this of itself is a sufficient objection to their use. Shoes and stockings are unnecessary and injurious, for the former cramp the feet and interfere with their exercise and growth, and the latter keep the legs wet and filthy, unless changed several times a day. Their night dress should be less than that worn by day, say only a loose flannel shirt, else the child will be liable to cold and affections of the bowels. Tape should be used, not pins, in securing the clothing, especially the napkins.

The negro children in slave countries are suffered to lie and tumble about on the floor from their earliest infancy in a naked state, and yet a deformed negro is very rarely seen. This is mainly to be ascribed to the absence of any pressure, such as made by the clothing common among the whites.

Children should be thus loosely dressed from their birth until they are three years old, when the effects of pressure from the clothing will not be so apparent. The only exception to this rule is in the case of weakly children, who, when they begin to walk, require the bowels to be gently supported. This should be effected by a thin flannel waistcoat, made to lace behind, from below upward. Beneath the laced part a slip of flannel may be placed to defend the skin, and which will afford support to the back This serves, in such cases, to prevent the relaxation and obstruction of the contents of the belly, and obviate a disposition to rickets and bowel complaints.]

SUBSECT. 5.—*Cleanliness, and Bathing of Children.*

6990. *Cleanliness, beneficial and wholesome as a habit generally, is especially requisite* in those who have charge of children, whose health and personal appearance are improved or otherwise, according as they are kept clean in their persons and habits. Bad food and bad air may weaken children, and deprive them of their elasticity of body and vivacity of spirit; but, if their skins are kept clean and wholesome, they will escape that squalid appearance which the poor children exhibit who are brought up under the combined evils of bad air, bad food, and uncleanliness. Inactive, perhaps vicious mothers (for such are always wanting in cleanly and orderly habits), neglecting to wash daily their children, to change their body linen, or keep their bedding as clean as, even in their poverty, might be done, must not be surprised if their children are subject to disagreeable eruptions, or more liable to the epidemic diseases of certain seasons of the year than the children of women of better domestic habits. But of such extreme cases of wretchedness we trust there is no need to speak here, except it be to point out that some of the great evils of life have a more aggravated character where cleanliness is wanting than where it exists.

6991. Of *tepid water*, rather than cold, we would advise the use in washing infants night and morning; and, especially if such children be of thin and delicate habits, washing in warm water is not only pleasant, but even nourishing.

6992. *Warm water*, therefore, we would not only employ at first in washing an infant, but continue to use it till the second year of his life. Any sudden use of cold water (we mean during cold weather, for, in the summer, water need scarcely be artificially warmed) we would carefully avoid, in order to prevent that distress at being washed into which some infants appear to be thrown whenever this needful business is in operation. When children cry during their washing, it leads one to think they are suffering either from the awkwardness of their nurses, or from the recollection of some former painful sensations attending this business. We would always encourage nurses to wash young infants very tenderly, in order to spare themselves the pain of hearing them cry, and the reflection that may be made upon their mode of handling and rubbing them. We know that much depends on the skill and carefulness of the nurse; she can do much towards making washing a pleasant or a vexing daily circumstance to herself and charge.

6993. *The best way of washing an infant of six weeks old* is to put it into a pan of tepid water, and, with a soft sponge slightly soaped, to gently rub the whole surface of the body and limbs: three minutes are enough time to effect that, when the child should be taken out, laid on the knee of the nurse (who on such occasions should wear a soft flannel apron), and rubbed gently, yet perfectly dry, with a soft linen towel. We must here insist as much on the benefit of the friction of the body and limbs as on the warm water; and while it is going on a child is often as happy and quiet as if the greatest pains were being taken to amuse it.

6994. *In the morning washings* the head, as well as the body and limbs, should be washed; in the evening it would be scarcely prudent to wet the head, especially if the infant has much hair. It takes too much time to dry it thoroughly in an evening, when the child is probably tired and wanting rest after the day's fatigue. To leave the hair insufficiently dried might incur the risk of giving the infant cold in its eyes or ears.

6995. *In drying* a child, friction should be less applied under the arms or in the bend of the knee than on the back, stomach, or limbs. Under the arms and behind the ears the towel should be gently pressed rather than rubbed: in those parts the skin is extremely thin and tender, and might be excoriated by much friction.

6996. *A child, after it is three or four years old*, may, in all general cases, be safely washed, night and morning, in a tub of cold water, except it be in the severe part of the winter, when a little warm water should be added to this bath. When these morning and evening washings are employed, there can be little necessity for using the plunging bath for children—formerly the panacea for all their infantile maladies; for rickets, scrofulous diseases, cutaneous affections, and emaciation, from whatever cause arising

How the shock and alarm caused invariably by a plunge into cold water could effect so much good it is difficult to imagine, except it was productive of that cleanliness without which the skin cannot perform its duty to the rest of the body.

6997. *Of cleanliness* in the clothing of children little need be said, since all are convinced of its importance to health. Yet, as some persons are fastidiously nice, and others too poor to be so, no rules can be well laid down as general guides in this branch of cleanliness. Mothers and nurses must regulate the use and change of linen according to their own judgment, applied to their own respective situation and means. Cleanliless sufficient for health is not extravagant in its requirements; and in the word health is implied moderation in the use of all the privileges of life.

SECT. IV.—NURSERY ATTENDANTS.

6998. *The head nurse*, one who has the entire charge of the infants of a family, should have health of body, vigour of mind, a well-regulated, yet cheerful temper, and undoubted integrity of heart. So important a post as this in a family should not be lightly intrusted to any one; for, in a household of domestics, which among them has equal power with the head nurse to work good or evil to those who employ her?

6999. *Whenever there is a head nurse* in a household, it is probable there is but little maternal superintendence of the nursery. To have such a domestic implies a rank in life in which minute attention to, or active occupation of, the mistress in domestic details is rarely found. In such rank, mothers see their children chiefly at stated hours, and generally in their drawing-rooms, not in their nurseries, where more might be known of their treatment. A lady frequenting her nursery at unusual seasons of the day, or for any length of time, will no longer lose caste in the eyes of her household. But should mothers of that kind still exist, the importance to them of having for their deputy in the nursery a trustworthy, sensible, good woman, not with eye-service, but in her heart performing the duties with which she is charged, is evident.

7000. *To the head nurse the exclusive charge of the infant* in a family always belongs. She washes, dresses, feeds it, carries it about, and in every way, as time advances, she attends to the development of all its powers. In all respects she ought to take upon her the mother's duties, and it is well for the infant when she discharges them faithfully.

7001. It will be needless here to enter into any detailed account of the treatment the head nurse should adopt in the rearing of infants committed to her care. In the foregoing section most of the important points are there given and discussed; and in all, even in the cutting out, making, and repairing of children's clothing, she will be expected to be skilful and diligent. We have said nothing respecting the making of children's clothing, because its style, and the materials of which the outward dress is formed, are in a constant state of change from the variations in fashion, and with which almost every nurse is as soon acquainted as the ladies whose children they have charge of.

7002. *The chief perquisites of* head nurses consist of the cast-off clothes of children, which should be done away with for very obvious reasons. Their wages are generally, in the high classes, from twenty to twenty-five guineas per annum.

7003. *The customs they are* obliged to observe are those of constant attendance in the nurseries, day and night. A head nurse having an infant under her care is never permitted to leave it, nor to allow under nurses to attend to it more than is absolutely unavoidable. When they can leave the nursery, it is only at night, when they resort to the housekeeper's room at the supper hour.

7004. At christenings, as a privilege, the nurse holds the infant; also, she always carries it into the drawing-room whenever it is required there, and again receives it when it is to return to its nursery.

7005. *Under nurses* are generally at the command of the upper, under whose superintendence they wash, dress, and attend, in every way required, to all the children in the nursery, except the infant, the exclusive charge of the head nurse. Under nurses do all the cleaning of the nurseries, make the fires and the beds, keep clean all the nursery furniture, and the various requisite utensils of earthen-ware. They bring the meals from the kitchen, and wait upon the children while they are at table. Sometimes they are required to assist in washing and getting up some of the children's clothes. In the evenings they assist in making or repairing the children's clothing. Good temper, cleanliness, activity, and a love of truth are important qualities in under nurses. Their usual wages are from eight to ten guineas per annum.

7006. *Of a nursery governess* we may venture to express a preference for an intelligent young person to one of great accomplishments, whose talents might be scarcely called forth, and who might better sustain her part in a family of older children. But although neither great accomplishments nor much learning can be requisite in the nursery governess, something more uncommon in her qualifications is in the highest degree important. We are not accustomed to regard the way in which the first seven or eight years of human existence are spent as unimportant, but very much the reverse: we therefore would seek in a nursery governess for a lady with such powers of mind and such excellent disposition as would enable and dispose her to call forth infantile observation; to fix it on suitable objects; to open and enlarge the infant capacity; to govern with gentle influence the wayward in temper; to encourage and give moral strength to the timid; to cultivate truthfulness to the very nicest degree, brotherly love, and consideration for all. Skill in the mechanical part of education (so to speak) is comparatively of no moment in the qualifications of the governess of early childhood, provided she can teach how to observe and inquire. Unfortunately for children, most parents think otherwise, and undervalue the rousing power, while they overrate the mechanical. It is true that reading, writing, arithmetic, means of acquiring future learning, *must* be taught to children, and there are times in each day which they could not better employ than in acquiring these arts. There are few ladies employed in early tuition who cannot cleverly instruct in even more than these. Yet they may not succeed in obtaining that influence over the minds of children, imperceptible, yet felt, by which their intelligence may be quickened, and their ductile affections regulated and directed. When such power exists over childhood, no deficiency in minor acquisitions should impair the value placed upon it.

[In America, as has been already remarked, this array of nurses is not deemed desirable, nor has it ever become fashionable, even among the wealthy, thus to multiply supernumeraries in the household. The housekeeper, a matronly lady, usually performs the office of "head nurse," by superintending both children and domestics. A wet nurse is employed, not for luxurious self-indulgence on the part of the mother, but as a measure of necessity in the cases in which the health of the mother, or her death, renders it imperative. Dry nurses are seldom relied on for rearing infant children, as but *little* confidence is felt in the safety of raising children by the hand; their services are therefore usually secured only for the older children, and as an assistant to the housekeeper. A child's nurse is very frequently employed among the domestics of the household, whose chief duties consist in holding the infant in her arms, carrying it out into the open air for exercise, and accompanying the mother in visiting, so as to relieve her from the fatigue of attention to the child, except at the intervals necessary for giving nourishment from the breast. As to the *nursery governess* here represented as indispensable, these duties ordinarily devolve on an elder sister, or other female relative who may be an inmate of the family. Indeed, it is found in most households that the multiplication of servants, or "helps," is to be deprecated, and especially in view of the difficulty of procuring trustworthy domestics in this country, which is much greater than in England. There multitudes aspire no higher than to be good servants, and such aim to excel in their several departments, and with the wages of such service they are content, and seek no higher condition. But here servitude is looked upon by most of those employed as degrading, and, however incompetent, they are wont to regard their condition when at service as beneath them, and to be submitted to only under galling necessity, and to be escaped from at the earliest opportunity. Indeed few servants can be found in America, unless among African slaves, who do not aspire after bettering their condition, and securing deliverance from a lot of servitude; and this, however eligible their home or liberal their wages. The fewer the servants, therefore, competent to perform the duties of the household, the better is it regarded by those who have had experience in housekeeping, for they are else liable to corrupt and spoil each other.]

CHAPTER II.

SICKNESS IN THE NURSERY.

SECT. I.—GENERAL OBSERVATIONS.

7007. The following suggestions regarding some of the diseases incidental to childhood are of a practical nature, and intended only for experienced mothers, nurses, or for any others who have the charge of the first few years of childhood. Among this class of individuals some are always to be found who indulge in an excess of apprehension when variations occur in the health of the children they have in charge. Others evince a different feeling; are either unconscious of, or supine when alarming symptoms of disease in children are really apparent. In the former case medical aid is often needlessly called for, in the other that aid is sometimes fatally neglected.

The following pages offer instructions to both descriptions of persons having this desirable end in view—the allaying of needless or the awakening of timely apprehension: herein no instruction or suggestion will be given that in its application would prove dangerous. The line beyond which the *non-medical* superintendent of the health of children should *not* pass is strictly defined, and the moment medical advice should be sought for is as accurately stated as the nature of the subject will admit of.

7008. *The common and simple* affections which attack the majority of children will be found in these pages plainly but briefly detailed, together with the symptoms of some of the more serious diseases, to carry out the object we have stated, namely, that trifling complaints may not cause unnecessary alarm, nor important cases easily escape observation.

7009. We would here remark that were much time expended in describing symptoms and treatment of severe diseases, however lucid and comprehensive such description might be, they could never qualify parents on such occasions to supply with safety the place of medical men. On the same ground, it will be useless to describe the complaints of the first few days of a child's life, because a medical man is at that time always in attendance.

7010. *Before* describing any particular disease, certain alterations in the natural actions of the child must be noticed, which, as denoting the occurrence of disease, are particularly important; they may be easily observed by the mother or nurse, and when noticed, they should be immediately mentioned to the physician or other medical man in attendance.

SECT. II.—ALTERATIONS IN NATURAL ACTIONS WHICH ARE TO BE OBSERVED BY THE NURSE.

7011. These deviations from accustomed action may be comprised under the following heads: Alterations *in the countenance* of an infant; in the gestures; in the cry; in the manner of sucking; in sleep; in the mode of breathing; in the skin.

7012. *Alterations in the Countenance.*—These are not lightly to be passed over. When there is pain in the head the brows are contracted, the eye is generally heavy and somewhat anxious: when in the bowels, there is an elevation and retraction of the upper lip.

Again, if pain be spasmodic, at the moment of seizure the brow contracts, and the child utters a cry; but the brow is not constantly knitted, as it is when continual pain is present.

In convulsions too, before the attack, a change in the countenance occurs, difficult to be described, yet peculiar, and well known to experienced nurses; for example, slight twitchings of the mouth, and unsettled rolling or else fixed gaze of the eyes.

Again, any, the most inattentive nurse, can scarcely avoid noticing any unusual flushing, or pallidity, or blueness, or yellowness of the face.

7013. *Alterations in the Gestures.*—Thus, a child will be observed to hang its head over the nurse's arm, as if too heavy for it; or to throw its head back or to the side, or to be constantly putting its hand to its head or neck; or rolling its head on the pillow. Such symptoms should never be overlooked.

A child may suddenly start, and this happens during attacks of spasmodic pain. In colic the child draws its legs up to its body; in debility, the extended position of the body indicates languor.

7014. *Alterations in the Cry.*—It should be noticed whether it be feeble, or its note altered from the usual pitch; whether there be moaning and sighing. In inflammatory diseases the child often abstains from crying, for fear of increasing the pain by movement. In commencing croup the cry, as well as the cough, is harsh, ringing, and metallic. In very severe cases of thrush the cry may become husky, but such cases are always under the care of a medical man.

7015. *Alterations in the Manner of Sucking.*—In thrush, in dentition, in fact in all cases in which there is soreness of the mouth, the child sucks feebly, with caution, and not long at a time, often leaving the breast for an instant, and then returning to it. The manner of sucking affords a tolerable estimate of the general strength of an infant.

7016. *Alterations in Sleep.*—The alterations particularly to be noticed, and reported to the medical attendant, are, sobbing, sighing, starting, knitting of the brows, drawing of the mouth, grinding of the teeth, quickened breathing, increased perspiration, or heat and flushing of face or skin generally.

7017. *Alterations in the Mode of Breathing.*—It is to be observed whether it is quickened or difficult, or more on one side than the other, or accompanied by moaning or rattling in the throat; whether the breath be fetid, or whether there be a cough.

Under this head it may be worth while to mention, that sometimes from a violent fit of crying, from passion, the child's face gets quite livid, and it almost seems as if it would be choked: a simple and generally successful remedy is plunging the child's hand suddenly into cold water; this induces a convulsive sob or sigh, and air immediately passes into the lungs.

7018. *Alterations in the Skin.*—These consist chiefly in eruptions of various kinds, which should always be attentively noticed; any unusual coldness, dryness, or, on the other hand, heat or much moisture of the skin, should not be allowed to escape notice. A singular purple streak at the verge of the eyelids was considered by Dr. Dennan as distinctive of the disease called "morbid shuffles," which usually appear after the first month. We have said nothing of alterations in the motions, the tongue, or the urine; these are too obvious to be overlooked. We have said thus much on these alterations from the natural state, because we are convinced that the importance of early noting them cannot be overrated. They mark, in some instances, the commencement of diseases, which, easily arrested by treatment in their early stages, may be in their developed attack intractable and dangerous in the highest degree. Again, they are much more easily discerned by the mother or nurse than by the physician, because the former knows the natural state of the infant, of which the latter is necessarily ignorant; and it is not the *mere presence* of these symptoms, but their presence as *alterations*, which should excite alarm.

Sect. III.—Diseases of Children.

Subsect. 1.—*Slight Diseases.*

7019. In addition to diseases common to all, children are liable to some peculiar affections, as croup, water on the brain (*Hydrocephalus acutus* of medical writers): there are also some affections more common in them than in adults, and which few children escape.

7020. *The arrangement we shall adopt* is recommended only by its convenience, and it is void of all pretension to technicality. We shall consider, under three heads, 1, a few simple complaints which are seen every day in the nursery; also, dentition and its consequences; 2, the early symptoms of certain serious diseases peculiar to, or more common in childhood, such as croup, convulsions, water on the brain, and the disease commonly called at the present day "remittent fever," and its consequence; 3, the commencement of certain diseases which commonly attack every one, as measles, scarlatina, smallpox, and hooping-cough.

The first disease we shall notice is an extremely common disease of the skin; it is generally called, in common language, "*red gum.*" It is often seen a week or two after birth; red spots are seen on the breast, back, loins, &c. It is generally of little consequence, and will frequently disappear with a dose or two of aperient medicine, or often without anything at all. In older children, and when more obstinate, it may sometimes be suspected to depend on an acescent, or, at any rate, altered state of the milk.

Another skin affection of little consequence is a blush of redness, with perhaps a little excoriation (*Intertrigo*), caused by neglect of proper cleanliness, and in parts rubbing on each other; it is easily cured by cleanliness, and the use of some simple ointment to diminish friction.

7021. *The next affection we shall notice is vomiting in the first months of life.* This often arises simply from repletion, or from temporary alteration in the milk of the nurse: the matter vomited is like milk, generally curdled, if it has been for half an hour or so in the stomach, and in colour white or slightly yellow. If it be hard, darkish, very yellow, in fact, much altered from the natural appearance of milk, then probably the cause is to be looked for in insufficient evacuation of the bowels (which should always after birth be acted upon), or perhaps the infant has been incautiously exposed to cold. In the first instance (when the vomited matter is simply returned milk), a little dill or anise seed water may be given; but often nothing more is required than to take care that the child does not suck too much at a time, or too greedily after fasting. If the vomited matter be dark and hard, and if the child be old enough, it is often necessary to give an emetic; a grain of ipecacuanha is a safe and gentle emetic for children of a month old; two grains may be given when the child is a year or more old. Should the vomiting still continue, a more dangerous cause than those now mentioned is to be apprehended, and no time should be lost in seeking medical assistance.

7022. Another extremely common and slight affection is *colic.* The child cries, starts when moved, and lies with its legs drawn up upon its bowels; there is much flatulence, the bowels are probably confined; when motions are procured, instead of the natural yellow, they are green or dark. In treating colic, the cause should always be attended to; too much healthy milk, or acid milk, or improper spoon meat, or insufficient evacuation, or exposure to cold, are among the most common causes: if the milk be in too great abundance, its quantity must be lessened; if it be acid, or if the spoon meat be improper, its quality must be altered; cold must be avoided; the bowels must be opened by calcined magnesia, with or without a little castor oil; rhubarb is too stimulating for very young children; warm fomentations should be applied by means of flannels, wrung out of warm water.

If the bowels are not moved, then medical aid is generally requisite, as sometimes, though fortunately rarely, colic passes into a dangerous disease, in which a portion of intestine slips down into the part immediately below it, and thus closes the passage (*Intus susception* of medical writers).

7023. *Diarrhœa.*—Induced often by causes very similar to those which are active in colic is a relaxed state of the bowels, or diarrhœa. It may often be traced to repletion, unhealthy milk, sudden changes of temperature. It often occurs in older children, from injudicious attempts to wean, from previous costiveness, and it is commonly said, also, from dentition, particularly of the double teeth. The motions are watery, and generally greenish, or, at least, altered from the healthy colour. Although often a very trifling affection, it should never be neglected, as sometimes it is difficult to check. The treatment depends upon the cause. If bad milk has irritated the bowels, it must be given up, and ass's milk, or the milk of a fresh nurse substituted, or a little beef gravy, rendered palatable by a little sugar, may be given: another tolerable substitute for the nutritious milk of the mother is the mucilage of barley or wheat mixed with a little gravy. If the diarrhœa result from change of diet, the infant should be fed only with the simplest food, as milk, the mucilage of wheat, &c. A gentle aperient will generally be sufficient to effect a cure; should it not, other measures become necessary, and a medical man should be consulted.

7024. *Worms.*—The following are some of the chief symptoms generally enumerated as characteristic of the presence of worms: irregular appetite, which is sometimes voracious, at other times languid; there is often a craving for food after a full meal; the bowels are sometimes costive, more generally loose; the motions are slimy and pale; often there is a little colic, and sometimes feverishness; the breath becomes fetid; there is often a livid circle round and under the eyes; after a time the child gets amaciated, and the abdomen becomes enlarged; the upper lip often becomes thickened, and sometimes also the nose; the child often picks its nose, and during sleep grinds its teeth. It seldom occurs that all these symptoms happen at the same time; and there is not one peculiar to and distinctive of worms. The most unequivocal are the irregular appetite; the craving for food after a full meal; the bowels at one time costive, at another relaxed, and the slimy characters of the motions: when these symptoms are present, worms may be suspected; but the only proof of their existence is seeing them in the stools. Such are the symptoms of two kinds of worms, the round and the tape worm (*Lumbrica Tænia*); into the treatment we do not intend to enter, as we are of opinion that in every severe case medical assistance is necessary. If aperients fail, the remedies, more particularly vermifuge, must be prescribed by the medical attendant. One remark may be made about the diet of children labouring under worms; it should be very simple, and not too saccharine. Sugar itself, when taken in excess, seems in certain habits to produce worms. A nutritious diet is generally necessary, for in these cases the health is often impaired, as evidenced in the pale, bloodless face, the white tongue, feeble pulse, and languor of body; indeed, such a state is often the precursor and the cause of worms; and removing it removes its sequence. Some practitioners suppose that neglecting to take salt with the food has some share in producing worms; and, whether this be correct or not, it is advisable to take the usual quantity, or perhaps even a little more. There is another kind of worm, called, in common language, the

7025. *Thread-worm* (*Ascarides; Oxyuris* of medical writers).—This worm makes its abode in the lowest portion of the intestinal canal; it seldom produces the severe effects ascribed to the round and tape worms. On examining the stools, it is easily seen; it is from a quarter to half an inch long, and, as its name denotes, of slender frame. These worms are easily removed for a time by injections of warm water, and their reproduction may generally be checked by injections of the infusion of the seeds of the *Santonica* (*Artemisia Santonica*), or of the solution of salt and water; or a good and popular remedy is solution of aloes in water. The best method of preventing them from increasing is to strengthen the frame generally, especially by the administration of the salts of iron, and a generous diet.

7026. *Thrush.*—Under this name popular opinion classes several distinct though allied diseases. We shall not attempt to discriminate these, but merely describe the disease in a superficial manner. By the term "thrush" is commonly understood small white vesicles, situated within the mouth, on the tongue, and inside of the cheeks; accompanying these there is generally a little derangement of the digestive organs; a little loss of appetite, or diarrhœa; the mouth also is sore, and the child sucks with pain and difficulty. It is more common in weak and sickly children, but it may appear in the most robust. All that is necessary for its cure is a gentle aperient; and in mild cases a lotion for the mouth, composed of borax and water, or honey, or a weak solution of nitrate of silver in water; this should be painted on gently with a camel's-hair pencil; not rubbed on roughly with the finger, or with flannel, as is sometimes done by nurses. In more severe cases, emetics are often useful, but to these cases a medical man should always be called in. Among the ill-fed and neglected children of the poor, and also sometimes in densely-crowded lying-in hospitals, a malignant and dangerous fever accompanies the thrush; or, to speak more correctly, of the intestinal derangement accompanying which the thrush is but a symptom. This complaint, however, is not common, and we shall not occupy any space by a description of it, as it should never be treated except by a medical man.

7027. *Dentition and its Consequences.*—It is customary among medical men, and those whom they attend, to attribute the majority of infantile diseases to this natural process. There can be no doubt that certain diseases do arise during the progress of dentition, and appear to be referable to it; but indiscriminately to lay to its account all the complaints of childhood, as some do, is little else than a confession of ignorance. The words of a French writer, Guersent, on this subject, may be quoted in support of this opinion. "On attribue," says he, "dans la monde, la plupart des maladies de l'enfance au travail de la dentition. La difficulté d'observer les maladies du premier âge, et le peu de connaissances positives que nous avons sur cette partie de la pathologie, ont contribué à emaciner cette opinion, et ce préjugé, resultat de notre ignorance, est ensuite devenu populaire comme tous les autres préjugés du médecine."—*Guersent, à l'article* "Dentition," du "Dictionnaire de Médecine."

Before enumerating and briefly noticing the diseases commonly ascribed to dentition, we shall make a few remarks on the appearances presented during the cutting of the teeth. It occasionally happens that one or two teeth are through even at birth, as was the case with Louis XIV. and with Mirabeau (*Billard*, "Traité des Maladies des Enfans:" Paris, 1833, page 260); however, the first tooth seldom appears before the seventh month after birth. About this time the child is observed to be fond of putting its fingers, or any hard substance it can get hold of, into its mouth; during sucking it will sometimes suddenly throw its head away from the breast; there is an increased discharge of saliva, which trickles down from the corners of the mouth; on looking at the gum it is seen to be swollen and rounded, and no longer to present the horny edge it possessed at an earlier period of life; by degrees the white colour of the tooth can be seen shining through it, and finally the thinned and yielding gum is entirely removed, and the tooth rises from its socket.

This process is often assisted by lancing the gum, which operation seems to be useful, not by dividing the gum, and thereby giving freer exit to the tooth, but by cutting through a little sac, in which originally the tooth was generated, and which, by becoming thickened, hinders the rising of the tooth. If the useful part of the operation be the division of this little sac, then it is evident that the lancet should always cut deep enough to grate upon the tooth. It may be that the lancing is beneficial by taking blood from the inflamed and painful gum. The statement which some have made, that, if the divided gum unite, it makes a firmer barrier than before against the tooth, appears to be unfounded; cicatrices are always more yielding than original tissues. In addition to the symptoms enumerated above, and which are always present, there are some others less common, and which may therefore be referred to unnatural dentition. These are, swellings of the glands in the neck, swelling of the hands and feet, feverishness, a difficulty in passing the water, &c.

7028. The diseases commonly referred to dentition as their cause, are, 1. Eruptions of the skin; 2. Emaciation; 3. Vomiting; 4. Diarrhœa; 5. Cough (inflammation of lungs); 6. Croup; 7. Convulsions; 8. Water on the brain; 9. Ophthalmia. Some of these complaints have been already noticed, as far as is consistent with our plan. One remark may be made about the diarrhœa attending dentition. It is an observation of Hippocrates that those children cut teeth fastest whose body is lax: common opinion has fully confirmed this remark; it has also gone still farther, and considered every diarrhœa during dentition as of use; and some writers direct such diarrhœa not to be arrested. Without entering into this question, one may safely say, that, if it arise from this cause, parents need not be alarmed about a diarrhœa, even if it be very considerable.

7029. *Rashes attending Dentition.*—One common rash is the red gum already mentioned. Very often the eruption has little watery heads, or resembles flea bites, but without the red point seen in the centre of these latter.

Another rash is one which sometimes leads parents to dread the accession of measles or scarlatina. It is a red blush, most observable on the extremities, but attended with little fever. Measles is preceded by running from nose, and a peculiar cough, and *scarlatina* by sore throat, and running from the eyes; and the absence of these symptoms in the rash now mentioned generally points out its real nature.

Another rash, presenting dull, red patches, chiefly on the legs, with here and there small swellings, is also sometimes seen. This is said to be more common when the eye teeth are cutting.

There are several other rashes, but less common than these, and which, therefore, need not be adverted to.

7030. The emaciation attending dentition is a consequence usually not immediately of the dentition, but of some of its products, as diarrhœa, fever, &c.

7031. The other disorders, as convulsions, croup, &c., will be noticed afterward.

7032. In all these cases it is, of course, difficult at once to put down the disorder to dentition; but as this *may* be the cause, it is proper in every instance to lance the gums well; and we may conclude this short account of the sequences of dentition by mentioning a remark made long ago by Dr. Underwood, that to effect permanent good it is often necessary to do this, not once merely, but many times, and on successive days; and with this remark the experience of most practical men will lead them to accord.

SUBSECT. 2.—*Early Symptoms of severe Afflictions most commonly seen in Children.*

7033. The first disease we shall notice is *convulsions, or fits*. A child is said to be in a fit when there are involuntary spasmodic movements of the muscles; the hands are clenched, the thumbs drawn in across the palms; the arms are bent and drawn to the side, or across the body; the feet and legs are drawn up; the muscles of the face distort the mouth, about which there may be a little froth; the eyes roll upward and inward, and the face becomes purple from a difficulty of breathing. After a short time the muscles relax their spasm, the eyes shut, the mouth resumes its customary appearance, and the child breathes easily, and seems quite recovered, or perhaps a little drowsy and heavy.

We presume that no parent would ever dream of treating such a disease herself; medical aid should always be promptly obtained. Very little assistance can be given in the fit itself; the head should be raised, everything removed from the neck, and, if the tongue be protruded and bitten, bits of cork must be inserted between the teeth, so as to prevent them from completely meeting. Throwing a little cold water in the face has appeared to some persons to be useful. The warm bath should be used, both in the fit and in the intervals.

Although we shall not enter upon the treatment of convulsions, we shall make a few remarks on some of the more common causes. Dentition certainly produces fits, and lancing the gums repeatedly often removes them. Too much food, and improper food, also, is a usual cause. After eating very largely, children have been known to die suddenly in convulsions. Again, too thick food in children who are brought up by hand without doubt produce convulsions: even after weaning, too much bread or rusk seems hurtful, by irritating the lining membrane of the bowels; the diet, therefore, should always be most carefully attended to, even if the fit should have proceeded from some other cause. Before the accession of smallpox, and sometimes measles, one fit or more will occur; and so far is this from being dangerous, that popular opinion regards it as favourable, and as indicating a mild attack, and certainly there is no reason for thinking that it foretells any particular severity of disease. In these cases the feet may be bathed in warm water, and a warm water injection may be given. In mentioning this, we may take this opportunity of recommending the warm water injection as a most useful assistant in securing a due regulation of the bowels in children.

We conclude this short account of convulsions by recommending in all cases the free use of mild aperients, particularly of castor oil, in doses proportioned to the age of the child.

7034. *Croup (inflammatory).*—Were medical aid sooner sought for in cases of croup, the mortality from this formidable disease would, no doubt, be very much lessened; but, unfortunately, few parents or nurses are sufficiently acquainted with those slight, yet often distinctive, symptoms which mark its early stage. At first the symptoms are those simply of a common cold; and at this time the dangerous sequence cannot always be perceived; but very often, in addition to the quickened breathing, there is an unusual resonance in the cough, something like a little metallic sound or barking; and when the child draws in its breath, there is a roughness in its sound, heard distinctly by the nurse when she places her ear close to the mouth of the child. Even in this stage the windpipe is often painful; the child raises its hand to its neck, as if to invite attention to the seat of its uneasiness. If proper measures could be taken in this stage, most children would doubtless recover; but if the parents wait till the breathing becomes much hastened and hoarse, and the cough hard and brazen, and till fever has set in, then the disease is much less easily subdued. It is much better to be deceived half a dozen times than once to overlook a case of croup; and we earnestly recommend all parents, immediately they perceive a roughened breathing and a resonant cough, and particularly if there have previously been symptoms of a cold, to lose no time in sending for medical advice. One of the best remedies in the early stages is an emetic; and this may be given without waiting for the physician: for a child of a year old, two grains of ipecacuanha is a proper dose; for two years old, four or five grains; for three years old, six grains; for four years old, seven grains; for five, six, and seven years old, eight or nine grains. An aperient may also be given, and the child should be placed in the warm bath. The other treatment must be left to the medical attendant.

Croup is more common on the eastern than on the western coast of England: it prevails most in damp situations, and in those exposed to the keen east or northeast winds. It is rarely met with before one or after eight years of age.

Before leaving this subject, we shall notice one circumstance in the history of croup which is calculated to excite fallacious hopes, and to lessen the assiduity with which remedial measures are employed—we allude to an apparent alleviation or remission of the disease which often takes place; for example, in the evening the child may be very feverish; the voice extremely hoarse; the cough violent, and loudly ringing; the neck swelled and puffy; the eyes watery; the head thrown back; in fact, all the symptoms of severe croup present: these things last through the night, but in the morning a great improvement may seem to have commenced; the fever has subsided, and the restlessness and anxiety have disappeared; the cough is lessened, and the breathing, though still roughened, is easier and more tranquil. But this improvement is temporary; with the evening all the severe symptoms return with augmented violence, and if the necessary measures have been omitted, much times is lost, which, in so rapid a disease, can never be regained. After an attack of croup, much care must be taken in avoiding cold winds and damp places; change of air is often beneficial: from time to time there may be a little recurrence of the cough and hoarse breathing, but these symptoms seldom continue, and need not generally excite alarm.

7035. *Inflammation of the Brain* (*Hydrocephalus acutus* of medical writers).—The observations made on the early recognition of croup are applicable also in this place. This disease, perhaps the most formidable and dangerous of all the diseases incidental to early life, and in its developed stage intractable in the highest degree, presents a short period only in which remedial measures can be used with any great chance of success. Fifty years ago recovery was rare; in the present day perhaps half of those attacked recover. This alteration is to be attributed, in part, to a more correct knowledge of the nature of the disease, and in no inconsiderable degree to the minute attention now paid to its early symptoms. Inflammation of the brain in children is generally seen between the second and tenth year: it is said to be most frequent in those distinguished for premature development of the intellect; certain constitutions seem to be more liable than others to its attack, for sometimes it affects every member of a particular family. In cases in which two or three children of one family have suffered from it, every, the slightest symptom must be noticed, and the signs which we shall presently enumerate carefully attended to. Inflammation of the brain in children may attack *suddenly*, but in the greater number of cases there are certain *warning* or *premonitory* symptoms, to which we particularly invite attention. These symptoms indicate derangement of the digestive organs: the child is noticed to have partially lost its appetite; seems dull and heavy; sleep is disturbed; and during sleep there is much sighing, and occasionally there is starting and crying; it seems as if the child were dreaming; the bowels are irregular, or more frequently there is costiveness, which is overcome with difficulty. When motions are procured they are seen to be scanty, dry, of a white, or, on the contrary, of a very dark colour, slimy, and fetid. Soon afterward there is feverishness; the skin is hot, the mouth dry, the child picks its nose and lips; there is thirst, and perhaps the breath is fetid. Very shortly afterward the child, if old enough, complains of pain in the head; the brows are continually knitted; the hands are raised to the head and back of the neck, and occasionally there is tottering in the walk; the child raises its foot as if to step over a threshold, as if there were some obstacle in the way; the eye presents a peculiar appearance, the expression is dull and heavy, but the eye itself physically is light and sparkling; there is often vomiting, and particularly on raising the child from the recumbent to the erect position; the tongue is dry, white, yellow, or brownish. If the child be too young to express itself, it may often be seen to hang and droop its head over the nurse's arm, as if it felt too heavy for it; the brow is knitted; there are occasionally fits of crying, and the expression of suffering seems often to have given a premature and melancholy appearance of age to the countenance. These symptoms are truly "*warning*;" but they do not always occur, or they may be slight and overlooked by the nurse, although evident enough to the eye of the medical man, who has been taught to observe them. Again, all are not usually present in a single case, and there are several diseases which resemble, in many of their characters, the early stage of inflammation of the brain. For instance, if the symptoms caused by worms are looked over, a great similarity is perceived in both diseases. There is loss of appetite, restlessness, grinding of the teeth, starting, sighing, irregularity and depraved condition of bowels, picking of the nose and lips, and feverishness. It is true that there are often certain differences; in one case the bowels are more often relaxed, in the other constipated (though this does not always hold good); the expression of the countenance is different, and, in worms, there is often craving after a full meal; and there are some finer distinctions, which the practised eye will alone recognise; but a nurse can hardly be expected to make these somewhat minute distinctions. Again, one form of a disease which we shall have occasion briefly to describe (gastric remittent fever of infants) presents many points of similitude to the warning stage of inflammation of the brain; and there are some other diseases which are somewhat similar. Dentition produces symptoms somewhat similar in young children. But supposing these more tractable disorders *are* mistaken for inflammation of the brain, and unnecessarily alarm, is it not better that this should occur twenty times than that a true case of inflammation should be once overlooked? And, moreover, inflammation sometimes succeeds to these, and is, as it were, ingrafted on them. We will presume, then, that when some, or all of the above symptoms occur, the prudent mother will endeavour to remove them; she will, perhaps, call in medical assistance, and this is the safest plan; but, for the sake of those who cannot always command immediate attendance, we will enumerate the chief measures to be adopted:

1. *Diet.*—Nature often points out, by the loss of appetite, that food is unnecessary, perhaps hurtful. If some appetite remain, food may be given; but it should be of the lightest and most simple kind, farinaceous and milky; its quantity also should be lessened.

2. The warm bath should be used once or twice a day; the child should be kept quiet, and not excited in any way; should take moderate exercise, but not too much: cold must be carefully avoided.

3. Aperients must be given. Now, although we are no friends to the indiscriminate employment of mercury in infantile diseases by parents, and wish to condemn in the strongest terms the use of calomel on the slightest occasions, we think that in the present case an exception may be made to our general rule. A mild preparation of mercury with chalk (*hydrargyrum cum cretâ*), known often by the name of "gray powder," is extremely useful in improving the condition of the bowels in the disease we are now considering. For a child of three years old, four or five grains may be given; for a child of seven or eight years, seven or eight grains; it should be taken at night, and followed next morning by a dose of castor oil, two, three, or four tea-spoonfuls, according to the age of the child. The mercury and chalk may be repeated on the following night, and the castor oil again the next morning. The mercury should not be repeated again without medical advice. The child perhaps may improve under this treatment, and the serious symptoms may disappear; but still, for some time, castor oil, the warm bath, and a careful diet should be used, and a recurrence of the constipation and disordered bowels must not be overlooked. If the disease does not yield, and the bowels get tender, and the headache and restlessness increase, no time should be lost in getting medical aid; it becomes necessary to apply leeches to the head and bowels, to give mercury in a more active form, and, in fact, to employ energetic treatment. Supposing that the warning symptoms we have described are overlooked or do not occur, certain symptoms ensue which indicate more directly the affection of the brain: the head gets hot, particularly at the front and back of the head; there is constant vomiting; increased heaviness; at times the child cries violently; the light seems to hurt the eyes; the pupil of the eye is contracted; soon afterward there is complete stupor, squinting, screaming, perhaps convulsions; the pupil is now dilated, not contracted; the pulse is irregular; the feet and hands become cold; the child seems sinking. Sometimes after this there appears to be a great improvement: the pulse rallies, the hands and feet recover their warmth, the extreme drowsiness and stupor disappear; the child sits up, recognises the by-standers, speaks rationally, takes its medicine, and hopes, unfortunately unfounded, are excited in the breasts of all but the medical attendant; for speedily the stupor returns, the pulse grows weaker even than before, a deadly paleness spreads from time to time over the drawn and emaciated countenance, cold perspirations bedew the skin with a clammy moisture; the convulsions, which may never have entirely ceased, augment in violence, and cease only with the increasing stupor, or terminate with life. This "lightening before death," as it is called in some parts of England, is, however, not very common; more generally the symptoms of stupor and convulsions never pass off, and death ensues suddenly in an attack of convulsions. The treatment of this advanced stage of the disease of course will not be described. Medical men should always be in attendance during the whole of the disease.

7036. *Remittent Fever in Infants.*—Our space compels us, somewhat reluctantly, to shorten our remarks on this very common affection. It is a disease most frequently seen between the ages of two and six. There are two chief forms in which it appears; in one case its attack is sudden, in the other gradual. In the first, or sudden form of attack, the child goes to bed apparently in perfect health, but in an hour or two is found with a burning, dry skin, a flushed face, and a quickened pulse; there is headache; the eyes seem red, and turn away from the candle; the child is very thirsty, restless, even a little delirious; there is pain in the stomach, and perhaps vomiting of a sour greenish or yellow liquid. Such an attack may generally be traced to over-eating, or to the assumption of rich and highly-spiced food, or, perhaps, after a meal of the usual kind the child has been exposed to cold and damp. If the attack seems to originate from a surfeit, then an emetic of ipecacuanha should be given, the dose the same as that mentioned under the head of "Inflammation of the Brain." After this an aperient of castor oil is useful. The warm bath should be used once or twice. The next morning the child may appear quite recovered, and sometimes really is so; but more frequently the feverish symptoms return in the evening, although, perhaps, not in so intense a degree. A few days' abstinence, mild aperients, and the warm bath will usually set everything to rights; but the attendance of a medical man is generally necessary.

The gradual form of remittent fever presents symptoms strikingly similar to those described under the head of "Premonitory Symptoms of Inflammation of the Brain;" and, indeed, there is no doubt that these two diseases are convertible into each other. This form of disease is often left after measles, scarlatina, hooping-cough, or any affection which exhausts the strength of the child. There is loss of appetite, a furred tongue, and fetid breath, costive, or, more generally, loose bowels and feverishness, increased, it may be, at some particular periods of the day. After a time the abdomen becomes enlarged, the child gets emaciated, and the skin hangs in folds, giving an aged appearance to the aspect; there is a hacking cough, restlessness, and perhaps great thirst, and, it may be, even a great craving for food, and much irritability if it be not immediately obtained; but more commonly there is loss of appetite; there is also very generally a propensity to pick the nose, upper lip, and any sore place or spot upon the skin. Treatment is often very successful; it is, however, diversified, and the attendance of a medical man is always necessary. The bowels should be kept open by rhubarb and castor oil, gentle doses of the gray powder (mercury with chalk) given every night, and the warm bath be used regularly twice a day. The diet should be very mild; barley water, thin arrow-root, and, when convalescence is approaching, chicken or veal broth. After a time tonics become very useful; but these at first must be of the mild and unirritating kind. In more severe cases of infantile fever the treatment is somewhat different; leeches and other lowering measures become useful; and medical attendance is necessary, to prevent the disease from running on into a chronic and dangerous form.

SUBSECT. 3.—*Commencement of some Diseases which few Children escape.*

7037. *Smallpox.*—The symptoms, in an unvaccinated individual, which would lead one to believe that an attack of smallpox is about to occur are the following: There is for some days after exposure to infection a degree of languor and lassitude, feebleness of the limbs, restlessness at night, and, it may be, a little loss of appetite, and nausea after taking food. In a few days more the patient feels chilly, and there is an undefined sensation of indisposition; shivering fits occur from time to time, and soon afterward pain in the head, back, and limbs, and at the pit of the stomach; in children a convulsive fit, or several fits, may occur, and these are seldom dangerous, and certainly do not indicate a particularly severe attack. There is often sickness and vomiting. Then, in about forty-eight hours after the first shivering fit, minute pimples are discoverable on the face and forehead; the sides of the nose, chin, and upper lip are the parts first affected; then the rest of the face, the neck, the wrists, and ultimately the rest of the body. These pimples may be far apart from each other, or set close together, so as to unite each other; from this two varieties have been made, the *distinct* and the *confluent.* The pimples increase in size, and a liquid is effused into them; in medical language, they become pustular, or, as the common people say, they acquire "heads." The fluid is at first clear, but it becomes, after a time, turbid and yellow. The majority of the pustules have a depression in the centre, which is characteristic of the smallpox eruption. After seven days the eruption is at its height; it then "turns," and yellowish or brownish scabs form, and drop off in the course of a few days more.

Immediately before the turning of the pustules there may be an increase of fever, the pulse becomes quicker, and there may be considerable delirium. The face swells; the eyes are closed; the feet and hands are swollen; there is considerable itching of the skin; and the child picks the scabs till they bleed, and form perhaps quite a sore place.

Such is a description of many of the milder cases; it would be here impossible to give an account of the many different and severe varieties which may occur.

It is impossible for any one to say with certainty, from the first symptoms only, that smallpox is impending; but the mother cannot do better than give an aperient of castor oil, the dose of which must be proportioned to the age of the child, and the warm bath may be used once.

During the course of smallpox the diet should be of the mildest kind; cooling drinks are very useful, and are taken with eagerness. The advantages of cool air and cleanliness are now universally acknowledged. It is, however, a practice among many old nurses, when they are engaged to attend children, to endeavour to "throw out the pock," as they term their object, by stimulating remedies, particularly saffron and aromatic waters with a little spirit. It is necessary in many cases to keep strict guard over nurses, lest they give more to their charge than is recommended by the medical attendant; and the old heating regimen was scarcely more injurious than the practice of giving saffron, spirits, and "Godfrey's cordial" in the first few days of smallpox. Any cough, or breathlessness, or hoarseness at an early stage of smallpox should be especially noticed and reported to the physician. The motions also should be observed every day; sometimes they are dark and slimy, but more frequently, perhaps, they are whiter than natural, and watery; in either case the circumstances must not be overlooked.

Various plans have been tried to prevent the "putting" of smallpox, a thing of great importance, on the face. From the structure of the smallpox pustule, we do not think any measures likely to be of much benefit. Sometimes letting out the fluid with a needle has appeared to be of service; medical men often try some other plans, such as covering the face with a mask of mild mercurial ointment, applying a solution of lunar caustic, but with little benefit. Drying powders, as of calamine or starch, may be used when the fluid from the pustules is very profuse. To lessen the itching, cold cream or sweet oil is often used, and the fingers of children should be covered with cotton wool, secured on by a linen glove, to prevent excoriation from continual scratching. In convalescence, nutritious diet must be very cautiously given; change of air, particularly at the seaside, is extremely useful.

7038. *Vaccination.*—In the present day, the advantages of Jenner's great discovery are everywhere felt, and universally acknowledged. Just conceptions of its value have superseded, on the one hand, the opposition of ignorance, and on the other the extravagant expectations of benefit which many of its early supporters entertained. Although in many cases its protective influence against smallpox is perfect, yet in others it fails; the causes of its failure are sometimes not obvious, but certainly this occasionally results from the vaccine eruption not running its proper course, but being deficient in some important particular. Our object, at the present time, is to portray its necessary changes, in order that any deviation from these may be noticed, and lead to a renewal of the vaccination.

It is customary to vaccinate children a few weeks after birth; unless the child be remarkably sickly, there seems no reason to prevent its being done when a week or a fortnight old; but as young children are not very susceptible of the smallpox contagion, it is often delayed for several months. The vaccine matter is inserted by means of a lancet, on the outside of the upper part of the arm. On the third day after its insertion the little wound or wounds, for several punctures are commonly made, appear red and a little swelled. On the fifth day a little vesicle is seen, filled with a transparent fluid; this vesicle is circular or oval. On the eighth day the vesicle is seen to have considerably enlarged; in colour it is yellowish or pearly, with a depression in the centre; the skin around its base is reddened, and this redness extends for a variable space, from a quarter of an inch in breadth to two or more inches; there is also some little swelling and pain; the child is often feverish and irritable, refuses the breast, and the bowels are a little deranged. The redness increases in degree, or, at least, continues in an intense degree till the eleventh day; it then begins to fade. The vesicle by this time has generally burst, and, drying up, forms a circular scab, of a brown or mahogany colour, which falls off in about seven or ten days afterward, and leaves a round scar marked with indentations. The glands in the neck are often swelled, and frequently a number of reddish spots appear over the body; they are of no consequence, and die away without any treatment.

It is of great importance to note these consecutive changes. If the vesicle, instead of being round or oval, tinged and depressed in the centre, is angular, pointed, with little or no redness round it, and if its contents are opaque and very yellow, instead of being pearly and transparent, the vaccination has not succeeded perfectly, and no security against an attack of smallpox can be reckoned upon. Or again, if the scab is a light yellow instead of brown, and falls off in a day or two, instead of sticking on for six or eight days, the process has not succeeded. Or if the redness round the vesicle has extended up to the shoulder and neck, or if the vesicle itself become converted into a sore, revaccination is necessary. In fact, any deviation from the regular and successive changes should be regarded with suspicion, and, as a matter of simple precaution, the child must be vaccinated again and again, till a proper and complete visicle be formed.

7039. *Scarlet Fever* or *Scarlatina.*—The degree of danger attending scarlatina, as in the cases of smallpox and measles, is very different in different cases. Sometimes the affection is so mild that it appears unnecessary even to confine the little patient in bed; at another time it is so severe that it is highly dangerous to life.

In the symptoms indicating an approaching attack, usually denominated "feverish," the child is first cold and then hot; complains of headache and pains in its back and limbs; feels sick, and perhaps actually is so. So far the case resembles smallpox, or the commencement of common fever; but, in addition, there are certain peculiar features, particularly in the severe form. One of these is sore throat, which may be exceedingly severe, pain about the jaws, difficulty in swallowing, running from the eyes, which look red and inflamed; and at this time the skin is often exceedingly hot, the face flushed, and there is intense pain in the forehead, or all over the head. We do not intend to assert that every feverish attack attended by sore throat is a commencing case of scarlatina; feverish symptoms accompany sore throat alone, as every one knows; but if with first chilliness, and then a hot and dry skin, headache, sickness, and loss of appetite, be conjoined sore throat, and if there is also running from the eyes, scarlatina should be suspected, and the case treated accordingly.

If it be a case of scarlatina, then on the second day after the accession of the febrile symptoms the rash appears on the face and neck, and gradually extends to the rest of the body, so that on the third day it spreads over the whole frame. It is of a strawberry red colour, and the tint deepens towards evening. Between two portions of the rash one may often remark a part of the skin of its natural colour. On the fifth day after its first appearance the rash gradually fades away, and as it does so the outer layer of skin in most cases peels off, or, in medical language, desquamates. Throughout the course of scarlatina the tongue is red and furred, the papillæ of it are elongated, there is thirst, quickened breathing, increase of fever towards night, and during the night perhaps even delirium; the nurse should notice whether there is any cough with the quickened breathing, and, particularly, whether any sharp, cutting pain is complained of in the chest or bowels—a circumstance which is often denoted by sudden screams, repeated from time to time, particularly when the child moves in bed; it should be observed, moreover, in what way the child ordinarily lies, whether more on one side than on the other, or whether on the back, with the legs drawn up or extended. The drawn-up limbs indicate pain in the abdomen; the extended, great debility

Treatment.—Supposing scarlatina is apprehended, the administration of an emetic is often of essential service: ipecacuanha should be given when the child is under four years of age; when above four years old, either ipecacuanha powder, or a preparation of antimony, commonly called tartar-emetic, may be used. The mode of giving this is the following: one grain, weighed very carefully, is dissolved in six ounces of water, and half an ounce, or about a table-spoonful, is given every half hour; in two doses the child is generally sick, and then the medicine may be continued every two or three hours, in the same doses; or, what is perhaps safer, discontinued till the arrival of the medical attendant. If the skin be very hot and dry, sponging with cold and slightly tepid water is very useful and agreeable to the child; cold cloths may be applied to the forehead to lessen the headache, and inhalation of warm watery vapour, by holding the mouth over a jug of boiling water, sometimes relieves the sore throat, if this be severe. Cool air and drinks are necessary, yet chilliness of the surface of the body must be carefully avoided, especially towards the end of the attack. It is, however, during convalescence more than at any other period that the well-directed attention of a parent becomes of the greatest value; too often with returning health come relaxing precautions; the danger is supposed to have passed; and yet at this time, as every medical man can certify, there is more real peril than during the height of the eruption; that is to say, more peril than in common mild cases, which are undistinguished by any malignancy of character, or any inflammation of internal organs. Exposure to cold draughts of air must be carefully shunned; the skin at this time is usually very susceptible of impressions; and by no means an unfrequent follower of scarlatina is a kind of dropsy, appearing chiefly in a swelled face and enlarged hands and legs; this almost always arises from exposure to cold and over-eating, and, as after mild cases little care is taken, it is more common after slight than after severe attacks. The diet, therefore, must be judiciously regulated; fermented liquids should not be given to children, from a mistaken notion of quickly restoring strength; the food should be nutritious, yet simple; country air is, after a time, very useful. When one member of a family has been attacked, immediate separation of the remainder of the juvenile part of it gives them the best chance of escape. A child will communicate infection to another after the eruption has disappeared, and sometimes even after the throwing off the skin has ceased. We shall make some remarks on purifying and fumigating rooms after smallpox and scarlatina when we have finished the subject of measles.

7040. *Measles.*—For several days before the appearance of the peculiar eruption of measles, there are certain symptoms which often excite a suspicion of the impending disorder. The child labours under a severe cold; there are watery discharges from the eyes and nose; accompanying these are irregular chills and shiverings, with general languor and appearance of illness. In the course of a day or two there is frequent sneezing, and a cough is generally heard of a hard, metallic, somewhat croupy character; the eyes are red, the tongue furred, and the breathing is often considerably oppressed. It will be easily observed that these symptoms differ considerably from those attending the early stages of scarlatina and smallpox: in the former, there is fever, with sore throat; in the latter, there are the peculiar and severe pains in the back, stomach, and head; but in neither is there the hoarse cough, the sneezing, and the discharges from eyes and nose which prevail in measles. On the fourth day, usually, after the commencement of the attack, when the symptoms above detailed are at their height, the rash appears. It is first visible around the head, behind the ears, and about the temples; it then appears on the rest of the face, then on the throat and neck; on the rest of the body a few spots, like flea bites, may often at this time be noticed; but the eruption has not reached the hands and feet until two days after its appearance on the face. The colour is less bright than that of the eruption in scarlatina; the rash, also, is not so universally diffused, is more patchy, and the patches will frequently be observed to have a crescentic or somewhat semicircular shape. On the day after its appearance on the hands and feet, the rash on the face begins to fade away; there is itching and scurfiness of the skin: at this time the eyelids are often swollen, but this soon abates, and the watery secretion from the eyes ceases.

The chief danger in measles arises from the occurrence of inflammation of certain parts of the lungs, and this is more frequent at the decline of the eruption; therefore, all throughout, but more especially at this time, any increase in the cough, shortness of breath, or symptoms of fever must be carefully looked out for, and their occurrence reported without fail to the medical attendant. At the close of measles a diarrhœa is extremely common.

7041. *In the treatment* very little can be done by the parent. Many writers advise an emetic, as in scarlatina; and if the child complain of sickness, it may be given. The cold sponging the body, so agreeable and efficacious in scarlatina, is not allowable in measles without medical advice. An aperient of castor oil or rhubarb may be given, with one or two grains of calomel, according to the age of the child. The apartment must be kept cool, but free from currents of air, and cooling drinks may be allowed in abundance.

7042. *Fumigation of Bed-rooms after the foregoing Diseases.*—We refer to the article on "Fumigation," for the detail of this subject. We may mention that during the course of the fever pure air should be freely admitted; and in bad cases it is often expedient to sprinkle a little solution of chloride of lime, or "bleaching liquid," as it is often called, upon the floor and in the utensils. After recovery, rooms are fumigated in various ways; some put a certain quantity of nitre in a hot saucer, and pour over it an equal weight of oil of vitriol (sulphuric acid). A more powerful means is the extrication of chlorine; this is done by placing in a vessel, heated to a considerable degree, equal weights of common salt and of the black or binoxyde of manganese, and pouring over them some sulphuric acid; all metallic furniture should be removed from the room, else it will be rusted. Nevertheless, often, after every means have been taken, the infection of scarlatina will adhere to a room for several months, even for a year; therefore, if possible, the room should be used by some one who has previously had an attack; as, on the whole, one attack certainly exerts a protective influence against a recurrence.

7043. *Hooping-cough.*—Many children escape hooping-cough, whereas few persons pass through life without having laboured under scarlatina and measles. In the present disease the child for some days seems to be effected with severe cough and cold; by degrees the cough takes on the hooping character; there is a series of little coughs which exhausts the breath, and consequently the succeeding inspiration is a long one; and, on account of certain structures being in a state of spasmodic contraction, a peculiar sound is produced; that is, *hooping.* During the coughing the child's face becomes very red; it seems struggling for breath, and as if it would be suffocated; but in a moment or two after the hoop is out, it is often running about as if nothing were the matter with it. The contents of the stomach are often discharged during the cough. Although hooping-cough is not a dangerous disease, it may become so at any time; in every case there is more or less inflammation of certain parts in the chest. This may become aggravated, or the head may be affected, and inflammation of the brain result; or in young children convulsions may occur, and be very troublesome and alarming; therefore, early medical aid is always necessary. We shall not describe the treatment, as we are of opinion that medical men alone are competent to understand this disease, and to treat the different stages of it with advantage. In convulsions the warm bath should be used. During convalescence, also, a change of air is signally useful, often removing immediately the remnants of the cough, and producing a most beneficial influence on the general health.

CHAPTER III.

CIRCUMSTANCES FAVOURABLE TO THE PRESERVATION OF GENERAL HEALTH IN THE FAMILY.

SECT. I.—DIET.

7044. *As a general rule*, the diet may have some variety; it must not be confined to one or two articles; there should be a mixture of animal and vegetable food. With regard to kind and quality, appetite and taste point out the best course; but then appetite and taste must not be perverted by condiments and spices.

7045. *The hour of meals should be regular*, and the meals themselves should not be more distant from each other than four or five hours; after a meal no exercise should be taken for at least half an hour or an hour; for if strong exercise be taken after a meal, the blood which would have been sent to the stomach, and from which the solvent fluid, the gastric juice, as it is called, would have been formed, is forced by the muscular contraction into other parts of the body; the food remains undigested, causing a load and weight to be felt at the pit of the stomach, and in a few hours often producing headache, a sour taste is felt in the mouth, and sometimes sickness. In such a case, if the sickness continue, an emetic of ipecacuanha (fifteen grains of the powder) is the best thing, and this should be followed up in a few hours afterward with an aperient mixture; but a short abstinence is preferable.

7046. *With regard to the taking of liquids*, cold water, the beverage provided by nature, is the best that can be taken; those who can be satisfied with this ought certainly to be thankful for it. Many persons accustom themselves, however, to take one or two glasses of wine every day, and, in some instances, such a practice seems beneficial; but if the quantity exceed this, the evils which the habit brings with it, in the long run, are not inconsiderable: the stomach appears to lose its power of secreting gastric juice without the ordinary stimulus; a degree of inflammatory dyspepsia is produced, and if, as is often the case, the individual increases the quantity of wine in order to get rid of the unpleasant sensations which torment him, he increases, at least in an equal ratio, his digestive disorders. Such a state seldom remains long uncomplicated; various gravelly and other disorders occur, and render life miserable.

7047. *All the evils which wine produces are caused in a still greater degree by spirits*; the most pernicious spirit is English gin, and one cannot be too thankful for any agency which seems to diminish in any degree, however slight, the consumption of spirits.

those who decry temperance societies should remember that, though total abstinence may not be needed in the middle classes, among the lower it is the *only thing* which is likely to reform them, for it is well known among medical men that the chance of curing a disposition to drink is much greater when the individual restricts himself to water alone than when he allows himself in a degree the use of fermented or spirituous liquors.

With regard to ale and porter, the same objections apply to these as to wine, though certainly with much less force; porter is often adulterated with compounds which make it heady; and ale, on the other hand, contains a large quantity of sugar and mucilage, which are digested with difficulty, and often produce acidity and heartburn.

[The preservation of general health in the family being the object of this chapter, the foregoing observations upon drinks are behind the times, and, besides, in some respects erroneous. That "one or two glasses of wine every day seems beneficial," and that the mischiefs of wine drinking are only "when the quantity exceeds this," is a dangerous doctrine. Men in health, it is proved by the experience of millions, are never benefited, but always injured, by the habitual use of wine, even in the quantity here prescribed. Nor is it found in practice that "one or two glasses of wine every day" will long be indulged without an uncontrollable inclination for more, and habitual wine drinking becomes intemperate drinking by a kind of physical necessity.

So, also, the use of spirits as a beverage is here commended to men in health, by the admission that "total abstinence may not be needed in the middle classes," and less needful, of course, in the higher classes, while "among the lower it is the only thing that will reform them." This is most pernicious doctrine, besides being unphilosophical and absurd. In America, "medical men" reason upon physical agents and their effects upon the animal economy, irrespective of "classes," only recognising cause and effect, as exemplified in invariable sequence. We do not admit in this country that English gin, or any other form of alcoholic spirit, can be taken into the stomach habitually with impunity, either among the "middle classes" or the higher, any more than the lower classes, and hence total abstinence is recommended from such drinks to all classes, as the best preservative of health.

Nor is it less exceptionable to represent the objections to the habitual use of ale and porter as applying with less force than to wine, for, apart from the "compounds" used to make these liquors heady, their alcohol is the worst compound they contain, and is never necessary to men in health.]

SECT. II.—REMARKS ON THE PRACTICE OF SMOKING.

7048. It is difficult to conceive on what grounds this practice can be defended; it produces indolence rather than excitement of the mind; it blunts the appetite, and, in some cases, it brings on an obstinate form of indigestion.

Tobacco contains a large quantity of volatile oil, which has a powerful sedative influence, often evidenced in the giddiness, sickness, and depression which follow the first attempts to smoke; after a time the system seems to accommodate itself, and to suffer little or not at all from this agent, but it would be against all reason to suppose that its effect ceases because less perceptible; on the contrary, the pale, bloated face, the indigestion, and loss of appetite, and the heaviness of mind soon point out that the habit is exerting a pernicious effect. It is true that some persons are able to smoke all day, and preserve their usual health; but this is no more an argument for smoking than the health and great age of a man who has taken his bottle of wine every day is an argument for drinking.

7049. *Smoking with a pipe*, moreover, causes sometimes a disease of the lower lip, which may become cancerous; at least this is not uncommon among the lower class of smokers in this country, who use the same pipe for a long time together.

7050. *Taking snuff and chewing tobacco* are also objectionable practices; the former blunts the sensibility of the lining membrane of the nose, destroys its susceptibility for odours, and thickens it often to such a degree that the person cannot breathe through the nose; besides, some of the snuff usually passes down into the stomach, and produces there the same effects as smoking.

Snuff-taking excites the mental faculties more than smoking does; at the same time, it is a still less cleanly habit.

7051. *Chewing tobacco* is a common practice, chiefly with seamen and travellers; it lessens the appetite very considerably, and is employed for this purpose by travellers, and others who have to endure long abstinence of food; its bad effects are, if anything, more strongly marked than those of smoking and snuffing.

SECT. III.—CLOTHING.

7052. This is a subject so well understood, that our remarks upon it will be very brief. In weak and scrofulous people, good clothing is one of the most efficient protectives against the consequences which exposure to cold brings with it to these persons. In cold and damp weather they should always wear flannel next to the skin, not merely over the chest, but all over the body from the neck to the feet; in summer, linen may be substituted for the flannel. (See Book XVII., "On the various Fabrics for Clothing.")

7053. One of the worst habits of clothing in the present day is the immoderate tightness with which some articles of dress are worn; tight cravats, when they were in fashion, not infrequently produced apoplexy; tight garters often cause enlargement of the veins of the leg and foot ("Varicose Veins"), by stopping the proper flow of the blood; tight stays, again, prevent due respiration, by hindering the movement of the ribs, and by pressing the lower ribs inward they distort the figure, and sometimes displace the organs in the abdomen. Supposing the arms to be separated from the body, the shape of the chest is a cone with a base or larger part below; but when tight stays have been worn for some years, it is not uncommon to find the chest small as usual at the top, then enlarging, and then again narrowing considerably, and giving a contracted and small, and what is by some considered an elegant, waist to the individual; but to those who know the true formation of the human body, a very narrow waist is not only inelegant, but is as displeasing as any other deformity of the person.

For information respecting the various articles used for clothing, see Book XVII.

Sect. IV.—personal cleanliness.

7054. The skin pours out continually a quantity of watery vapour, with a little saline and gaseous matter; this *secretion*, as it is called, is generally in so small a quantity, and so gradually formed, as to be imperceptible, and then it is known by the name of "*insensible perspiration.*" At certain times, however, from the effect of exercise, of clothing, of heat applied in any way, or of particular medicines, this insensible perspiration is increased so much as to form drops of fluid obvious to the eye, and then the secretion is designated by the term "*sensible perspiration.*" The quantity of water got rid of in twenty-four hours by insensible and sensible perspiration is very great, perhaps on the average as much as a pint and a half in round numbers. It is obvious at once how necessary it is to keep in a proper state the organ from which this vast quantity of fluid is constantly draining; if, in regard to cleanliness it be neglected, it becomes dry and harsh, and unfit for its functions; some other organ must then supply its place; but this other organ may have too much to do, thus working for both, and may become diseased; in fact, neglect of cleanliness of the skin is a most fertile source of disease, both of the skin itself and other parts. Cleanliness in our habitations is as necessary to health as personal cleanliness; all exhalations from decomposing animal and vegetable substances produce themselves certain complaints, and also increase the violence of other diseases in a very great degree. But this subject has lately attracted so much of the public attention that it is needless to enlarge upon it. On this subject, see farther in Book XIX.

Sect. V.—bathing.

Subsect. I.—*General Observations.*

7055. In every age, and almost in every country, even among uncivilized nations, the value of bathing appears to have been acknowledged. The perfection and luxury of baths among the enlightened nations of antiquity excite our admiration, and in many parts of the world public baths still form remarkable features. Bathing may be considered in a twofold point of view: as hygiene, or as a means of preserving health, by keeping the skin in a state fit for performing its functions; and as a therapeutic agent of great power, or for the cure of diseases. In a general sense, it means the immersion of the body in a fluid different in kind or temperature from the common air. Water is the ordinary medium employed for baths, but vapour and heated air are likewise in use for the purpose.

7056. There had long existed in this country a prejudice against bathing, or at least a degree of apathy rather surprising, indicated by the almost entire neglect of providing means for public bathing. Bathing was in the last century considered rather as a pastime and luxury than with a view to the improvement of health; but at present this is considerably altered; medical writers point out its value, and the public is beginning to be awakened to its importance to all, and particularly to the working classes. Still we are far behind in those conveniences which are essential to its general practice; and the expense and trouble attending bathing prevents its being so much employed as it might be. In France, advantages are placed within the reach of the poor to which the rich alone can aspire in other countries. The number of gratuitous baths which are given at the hospitals of St. Louis and La Charité is truly prodigious; in 1822 it amounted to 127,752 for the out-patients only of the hospital of St. Louis. In Paris the habit of bathing is so general that the public baths are extremely numerous and cheap. We are only beginning to imitate what has been long established in that way in other countries. Bathing machines at the seaside, which are but of late origin, have diminished the difficulty at the various watering-places; but the use of baths is not yet of sufficiently easy accomplishment except to the wealthy, who can have them in their own houses.

The great use of bathing must be obvious when we consider that the skin is not to be regarded as a mere covering of the body, but as an organ, the healthy condition of which is of vast importance to the well-being of the whole frame, but especially of the stomach and lining membrane of the lungs, with which, as mucous membranes, it has the closest sympathy. Taking the lowest estimate by Lavoisier, the skin appears to be endowed with the power of removing from the system, in the space of twenty-four hours, twenty ounces of waste. The retention of this, from neglect of changing the clothes or other causes, is productive of much injury to the system.

7057. *The most important circumstance respecting baths of every kind is their temperature:* various subdivisions of baths, according to their temperature, have been adopted by medical writers; but it must be obvious that every classification of this kind must be in some degree arbitrary, it being impossible to limit the degrees of warmth in each with perfect accuracy; still it is convenient to have distinct expressions for baths of different degrees of heat. The simplest division is into *cold* and *hot* baths; the former comprehends all those which communicate the sensation of cold, the latter all which occasion the feeling of warmth: all baths below 88° of temperature may be denominated cold; all above, warm. Medical practitioners subdivide them still farther into, 1, the cold bath, from 33° to 60°; 2, the cool bath, from 60° to 75°; 3, the temperate bath, from 75° to 85°; 4, the tepid bath, from 85° to 92°; 5, the warm bath, from 92° to 98°; 6, the hot bath, from 98° to 112°.

Subsect. 2.—*Cold Bath.*

7058. *The temperature of the human frame* in a state of health continues nearly the same in whatever circumstances it is placed. This in an adult is generally from 97° to 98°. In some cases of disease the temperature is above this standard, even as high as 106°, while in others it sinks far below this standard. The functions by which the body is enabled to preserve this uniformity of temperature are intimately connected with the nervous system and the respiratory organs by which heat is developed. The skin performs the function of regulating it, especially in reducing it when too high. When the body is placed in a medium or lower temperature than itself, the heat is abstracted more or less rapidly from the surface, which would have the effect of chilling it were not this counteracted by the internal development of heat. When surrounded by an aëriform medium much higher than itself, the exhalations from the surface both of the skin and lungs are greatly augmented; that from the former being thrown off in the form of perspiration, that of the latter in the form of vapour; the evaporation attending these processes occasions a reduction of temperature. *The cold bath includes* immersion in cold water, or that of a temperature from 33° to 65°, whether in the open sea, rivers, ponds, &c., or in large or small baths under a roof.

7059. *It is proper first to consider the usual effect of a cold bath* on a person in good health, who uses it only as a measure of hygiene. On immersion, there is first felt a general sensation of cold, proportioned to the lowness of the temperature of the water, and if the immersion be sudden, a peculiar impression on the nervous system is felt, forming a shock to the whole system, which is one of the most important circumstances belonging to the use of the cold bath; the skin shrinks, becomes cooler and paler, and the respiration is more hurried than before; but this is almost immediately succeeded by an equally universal sensation of warmth, which increases rapidly to a certain point, so as to cause the surrounding water, though actually cold, to feel comfortable; and this feeling is sooner produced, and continues longer, in proportion as the person is in full health and naturally possesses a vigorous circulation. By degrees, however, if the body continues immersed, it becomes chilled; violent shivering comes on, the extremities become numb and pale; sometimes sickness takes place, and at last the animal powers are exhausted by cold and fatigue. In this process, the most remarkable effects are those which occur first, and are directly consequent to the shock of immersion; and it is only when it occurs that the cold bathing should be suffered to proceed.

7060. The sensations of returning warmth which take place directly after the cold of the first immersion constitute what is called the *reaction of the system.* Medical writers explain this reaction by stating that the almost instantaneous result of the shock is the excitement of the nervous system to increased activity, in virtue, no doubt, of that general principle of self-conservation bestowed in a greater or less degree on all living, organized beings. The fluids are repelled from the surface to the internal organs, which are thus stimulated and roused to action; in consequence of which the blood is propelled through the whole capillary system, more particularly of the surface, carrying with it life and renovated energy.

If the bath is left before the second attack of shivering, or before this has continued too long, the bather generally experiences, on dressing, a renewal of the reaction which had followed the shock of immersion; and this having now nothing to counteract it, becomes more vivid and permanent: the pulse becomes fuller and stronger than before immersion; the skin recovers the plumpness it had lost; all sense of oppression and langour vanishes, and is succeeded by a feeling of buoyancy, and an agreeable consciousness of increased animal power. No second glow ever succeeds the second chill above mentioned, but the debility increases with the length of the immersion.

7061. *The whole effect may be distinguished into,* 1, the shock, the effect of which is stimulating; 2, the cooling effect; 3, the counteracting or astringent effect; and, 4, the reaction. Cold bathing may be applied so as to ensure one or other of these actions over any of the rest, according to circumstances, when all are not desired.

7062. *The cold bath, when used by persons in health*, increases the tone of the habit, strengthens the digestive organs, and by diminishing the sensibility of the whole system, and particularly of the skin, renders the body less susceptible of atmospheric impressions from cold, wet, and sudden changes of temperature—thus contributing to the production of what is termed a robust or athletic constitution; hence the beneficial effects of using the cold bath daily, and that early in the morning when just out of bed, have been experienced by persons engaged in such service as the ordnance survey, where they have to ascend high lands, and are thus exposed to a frequent change of climate.

7063. *Where the shock, as a stimulus to the nervous system* in cases of debility, is the principle desired, the water should be very cold, and the time of remaining in the bath should be only momentary; and after the first plunge the bather should leave the bath, and be wiped dry with towels in order to bring on the reaction. The water may be even dashed on, in the manner called the *douche*, which see.

When the object is to obtain the refrigeratory action of the bath with as little as possible of the nervous shock or vascular reaction, as in the case of febrile diseases and local inflammation, the water should not be applied, at first, at a low temperature, nor suddenly; it should be only cool, and applied with a sponge, repeating the application till the desired effect is produced.

7064. *It is chiefly in chronic diseases* that the cold bath is employed for a length of time; and it is then principally the secondary effect, the glow or reaction, which is desired. The rules to be observed in order to obtain this effect are founded upon the strength, which is generally inferred from the age of the individual. The degree of reaction is, for the most part, dependant upon the coldness of the water, and the length of time the person remains in the bath. Very cold water, in which the person remains but a short time, will, in general, produce a greater degree of reaction than a more moderate temperature in which he remains longer. But here much depends upon the general power of the individual, the state of his system, especially of the skin at the moment of immersion, and the nature of the bath according as it is fresh or salt water, and also the season of the year.

7065. *The effects of the cold bath have been described very differently* by physicians; some have considered it as a stimulant, others as sedative or tonic, or even debilitating; but the truth is, that its operation varies according to circumstances, namely, the mode of using it, and the condition of the patient. It may be debilitating in a case where the strength of the patient is exhausted, yet tonic in the highest degree in another when properly applied. As the reaction is commonly proportioned to the vigour of the circulation, particularly that on the surface, and to its warmth, it should be a rule, that persons with a feeble circulation and cold extremities should endeavour to invigorate the circulation and increase their temperature previously to going into the cold bath. Many imagine that, when they are made a little warm by walking, they ought to wait till the body is quite cool before they go into the water; but this idea has been shown to be erroneous; and Dr. Currie has recommended that a little exercise should be taken previously to cold bathing.

If, after coming out of the cold bath, the person feels dull and chilly, or complains of headache or tightness across the chest, it is a proof that it disagrees, and it should accordingly be discontinued.

7066. *With respect to the length of time to remain in the cold bath*, from ten to twenty minutes is sufficient even for the strongest constitution, and is too long in very cold weather. A cold bath in a cold place is far from being comfortable; and after coming out of the bath, the body should be dried in a room or place tolerably warm, that the reaction may be encouraged.

7067. *The morning is generally the best time* for the employment of the cold bath, the temperature of which should bear a relation to the time of year and the temperature of the weather, as well as to the strength of the person using it. It is an error to use cold water at night; the frame, after the exhaustion of the day, is more in a state for the soothing influence of warm water. In some cases, however, it may be proper to use tepid water in the morning, and to avoid the relaxing effects of warm water in the evening. For persons of delicate constitution it is best to fortify the habit with a good breakfast, which should be taken at least an hour or two before bathing.

7068. *The reaction is increased* by using some motion or exercise when in the cold bath; swimming is, therefore, advisable when the bather has sufficient skill and the bath is sufficiently large; but care should be taken that the stay in the water should not be too much protracted. Friction of the skin after the bath conduces to a beneficial effect, by producing a healthy glow.

7069. *The cases of disease for which cold bathing is a valuable remedy are*, morbidly increased irritability and sensibility, accompanied with general debility. When there is a tendency to colds and rheumatism, the cold bath is an excellent preventive; for this purpose, it should be used continually throughout the year, and the chest should be sponged with cold water, or vinegar and water may be substituted in winter, when there are not facilities for using the complete bath. Delicate and feeble persons of all ages require a higher temperature of the bath, and a shorter stay in it than others. It is proper for such persons to begin a course of cold bathing by the use of the tepid or temperate bath, lowering the temperature gradually ; or perhaps a glass of wine or a cup of coffee may be taken before entering the cold bath. It is a good rule to wet the head previous to taking the plunge.

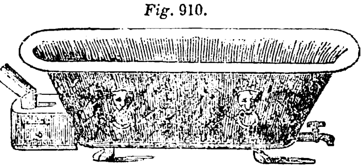
The cold bath is improper in chronic inflammation of the mucous membranes of the bronchi and intestinal canal, except when these are very slight ; but it is beneficial in certain cases of chronic catarrh, attended with little or no inflammation of the bronchial membranes, particularly in the dry catarrh, and in those forms which seem to depend rather on a relaxed than an irritated state of the bronchial membrane. In no disease is the cold bath more beneficial than in the intervals of asthma, when the system is in other respects proper for the remedy ; its principal action in this case is, no doubt, as a preventive of catarrh or cold, which is by far the most frequent exciting cause of the disease.

Neither is this remedy suited to those who have a tendency to consumption, nor to such as are constitutionally liable to bowel complaints. Before attempting cold bathing, careful investigation of the state of the mucous membranes of the chest and intestinal canal should be made, as it will certainly prove hurtful where chronic inflammation of these organs exists.

7070. *The size of the bath* is of some consequence. It is observed that bathing in the open air is of a more tonic or bracing character than bathing in a confined apartment. In the domestic bath the patient can seldom have the advantage of a complete and sudden immersion, and exercise while in the bath is almost totally precluded. It would be desirable that a room for bathing should be constructed in every house ; and though this is scarcely possible in the present condition of society, yet a bath should be considered as indispensable in every mansion of considerable size. It may be lined with marble slabs set in Roman cement, which is the most elegant and cleanest ; it may also be constructed of brick coated with cement, or with tin plate painted. The bath should have a supply of cold and hot water by pipes and cocks, together with a pipe for emptying the bath, steps for descending, &c. Baths of this kind have been frequently constructed of great elegance ; but what is most wanted is a convenient bath of small expense, so as to be within the acquisition of persons in moderate circumstances, and such baths are most conveniently placed in the bed or dressing room. In some of the London club houses and hotels, by means of the back boiler of the kitchen range, hot water is made to ascend to the baths in an upper story without any mechanical means being employed ; but this requires that the water in the boiler should always be kept boiling. In many houses in the west end of London the water rises to the bed-chamber floors by the high-service pipes of the water companies. Water may likewise be raised to the upper part of a house by a well-constructed force-pump ; and it would not be difficult to heat it in the bed-room floor. Although it would not require any great exercise of ingenuity to contrive baths in the bed-chamber stories, yet scarcely any houses of an ordinary class are furnished with so valuable an addition, the chief difficulty being the regular supply of water. It would be exceeding our limits were we to say anything on the subject of public baths farther than to point out their great utility, and to express a hope that the increased attention to the means of preserving health, which must be the result of the diffusion of knowledge, will, in no very distant period, produce all that can be desired.

7071. *Portable baths* of various kinds are made and sold in ironmongers' shops. *Fig.* 910 represents a full-sized bath of tin plate painted. Other portable baths which may be used for cold water are represented in *fig.* 911, shower bath ; *fig.* 915, hip bath ; *fig.* 916, leg bath ; and *fig.* 917, foot bath. See child's bath under "Nursery Furniture."

Fig. 910.



SUBSECT. 3.—*Temperate Bath.*

7072. This is analogous in its effects to the cold bath, but in a less degree. The Buxton water, which is of the temperature of 82°, is the best natural example of this class of baths. It may be prescribed in cases where the shock of the cold bath would be too violent for the patient ; and it may sometimes serve as a proper preparation for the cold bath.

SUBSECT. 4.—*Tepid Bath.*

7073. The tepid bath is more important for the purpose of cleanliness and the general preservation of health than as a remedy in disease, although in the latter case it is often very valuable. The range of temperature extends from 85° to 92° ; and it is sometimes employed previous to the cold bath, the bather lowering the degree of heat gradually each time until he arrives at that of the cold bath. The shock of this bath at the lowest temperature is slight when compared with that of the cold bath, but on that account is better suited to certain invalids, while its highest temperature partakes of the nature of the warm bath. For the mere purposes of ablution, the occasional use of the tepid bath of about 85° to 90° is the best, choosing the particular degree that is most agreeable. The best time is noon. Brisk exercise in the open air should be taken afterward. It is very refreshing after fatigue and travelling, and is equally serviceable occasionally to persons of sedentary habits. It is not proper immediately after a meal, nor when the person is much excited by wine; before using it, the heat of over-exercise or much excitement of mind should be suffered to pass off. Water by itself, warm or cold, is but imperfectly cleansing, as the perspiration cannot be readily dissolved and carried off by water alone; hence the advantage of employing soap of some kind when mere cleansing is required.

Subsect. 5.—*Douche Baths.*

7074. The douche bath is a powerful agent, and consists of a stream of water, cold or warm, directed with considerable force from a tube upon some particular part of the body, and varies in its power, according to the diameter of the stream, the temperature of the water, and the force with which it strikes the body. The cold douche is employed in inflammatory diseases, such as that of the brain, and in mania. The water is sometimes made to fall through a pipe from a reservoir placed at some height; and pouring water from a large tea-kettle or other vessel may be used as an inferior kind of it. The douche is much employed in the Oriental vapour and Russian baths in conjunction with vapour. There are natural douching baths of warm water in many parts of the world, as Aix les Bains in Switzerland, which are well described by Mr. Bakewell in his "Travels in the Tarentaise." The water, at a temperature of 110°, but somewhat reduced before it reaches the patient, descends upon the patient in columns as large as the arm, from a height of eight to ten feet. This is described as an operation unpleasant and exhausting, but it produces a profuse perspiration on the patient being put into a bed. It is found to be relaxing and beneficial in chronic rheumatism, sprains, and stiffness of the joints.

It is supposed that much of the advantage derived from the douche depends upon the percussion upon the part affected by the descent of the stream of water, since the height of the fall is important. When a sufficient height cannot be obtained, it is stated that the effect may in some degree be imitated by striking the part of the body to be douched with a hammer made of caoutchouc while the stream of water is acting upon it; but it is evident that this process can be practised only under the immediate direction of the medical attendant.

Subsect. 6.—*Shower Bath.*

7075. The most convenient form of cold bathing is the shower bath, already much in use. By this the water may be easily adjusted to the necessities of the bather as to its temperature and quantity, and whether it be fresh or salt. The bath takes up little room, and it may be placed in the bed-room or dressing-room.

The effects of the shower bath are, upon the whole, nearly similar to those of the plunge bath, but there is some difference between them. The shock from the shower bath is, in general, felt to be greater than that from simple immersion, particularly if the quantity of water be great, its temperature low, and the fall considerable. It sometimes happens, too, that a patient can bear one better than the other. Its effects are more speedy, and extend more to the internal organs than those of the common bath; consequently when recourse is had to it, the patient should withdraw immediately after the shock; the glow felt is almost immediate when it is beneficial; if its use is prolonged, it quickly lowers, and at last destroys, the sensibility, being then highly injurious. It should seldom be resorted to without medical advice, and it may be used either cold or tepid.

When cold water is used, the effect as a tonic is very advantageous, provided the habit is sufficiently vigorous to produce the proper reaction and glow on the surface immediately after the shower; but for delicate persons the tepid shower bath is preferable. Salt added to the water is an improvement. In certain affections of the head the *cold* shower bath is found useful; if required, the feet may be immersed in warm water while cold is applied to the head and body. Some recommend promoting the reaction by the friction of horse-hair or coarse flannel gloves. The best time for using the shower bath for hygiene purposes is immediately after rising in the morning; but in weakened habits an hour after breakfast is better.

7076. *Fig.* 911 represents the form of a shower bath as it is usually sold by ironmongers. The water is forced up into a cistern, *a*, with a perforated bottom, by a syringe, *b*, and the bather, by pulling a string, opens a valve, which causes the water to descend suddenly in a shower on his head and body through the perforated bottom. A receptacle at the lower part receives the water, and curtains confine it from splashing about.

To prevent the dampness in the room occasioned by wetting the curtains, they may easily be made to take off, and may be dried elsewhere. The whole is made of tin plate painted, one of the upright supports being hollow, to allow the ascent of the water. The usual price is from £3 to £5.

Fig. 911.

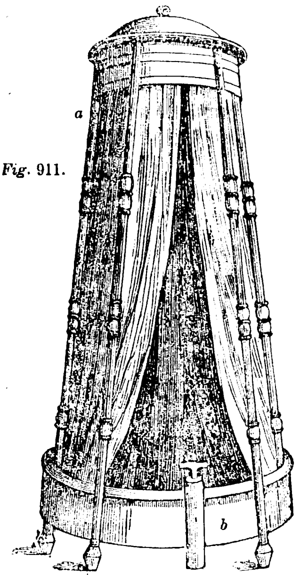


Fig. 912.

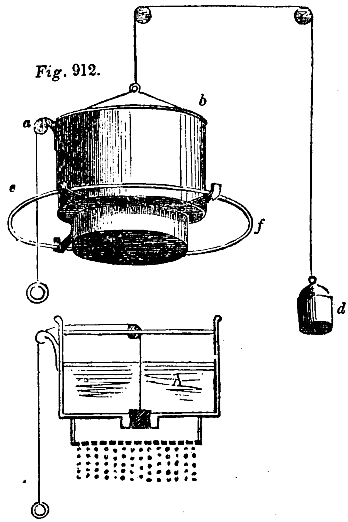
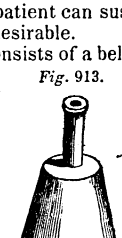


7077. *An apparatus for this purpose*, *fig*. 912, much cheaper, and answering nearly as well, has lately appeared in the shops. *a b* is the cistern to hold water, and it is suspended from the ceiling by a line, *c*, and balanced by a weight, *d*. The valve in the interior is on the same construction as in the upright shower bath, *fig*. 911, and is shown in the section A. An iron ring, *e f*, is attached to the cistern, from which the curtains hang, and another iron ring, but larger, keeps out the bottom of the curtain. The price of this apparatus is only from twelve to sixteen shillings.

7078. *When economy is an object*, a shower bath may be easily made on a cheaper plan. A wooden tub will do for the lower receptacle, to the side of which may be nailed two or three uprights of wood, having at the top some kind of pail with a perforated bottom, or a large tin colander would answer, into which an attendant, on a pair of steps, might pour water; a hoop at the top of the uprights might support a curtain of calico. Even simpler forms may be contrived by persons of ingenuity. The small quantity of water required by the shower bath is a circumstance of great convenience. If the cistern is contrived so as to hold considerably more water than is necessary, the patient can suspend and renew the shower at pleasure, which, in some cases, may be desirable.

7079. *A shower bath for children* has been lately brought into use. It consists of a bell-shaped tin vessel, *fig*. 913, the bottom of which is pierced full of holes, a hollow tube rising from the top, the aperture of which can be closed by the pressure of the finger. To use it, the bell must be sunk in a pail of water, and when it is full the forefinger is to be pressed hard upon the top of the tube, so as to close it perfectly. The bell may now be raised out of the water, and by means of the pressure of the atmosphere, as in the case of the barometer, it will continue full until it is lifted over the head of the child; when, by withdrawing the finger from the tube, the water is discharged in a sudden shower through the numerous holes in the bottom of the bell.

Fig. 913.

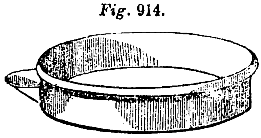


7080. *Cold affusion*, or throwing cold water on the naked body in disease, to reduce its temperature, is a rude form of the shower bath, and is more sudden and decisive than it. It is sometimes used in fevers by the advice and under the superintendence of a medical man, and should seldom be intrusted to others.

Subsect. 7.—*Sponging*.

7081. *Sponging the body* with cold or tepid water may be enumerated as one of the modes of bathing. In cases of febrile diseases, the object in sponging is to reduce the heat of the surface; but as its action is powerful, it should not be employed in this case except by direction of the medical attendant. It is sometimes performed while the patient is still in bed; the night dress being stripped down, and a large cloth tied round the waist to prevent wetting the bed-clothes, while a wet sponge is passed over the body; or a wet flannel is applied to the skin, after which the body should be dried by a gentle or brisk friction. In other states of the patient, he may sit up in a chair, while two or three persons rub his whole body with large sponges wetted, after which he is to be wiped dry and put into bed. The process should not be attempted while there is the smallest tendency to perspiration. Sponging is likewise used successfully as a tonic to ward off disease. It is found particularly serviceable when a person is disposed to asthma, or the disease of the lining membrane of the bronchial, or air tubes leading to the lungs, commonly known by the name of a *cold*, or common *cough*. For that purpose, the chest may be sponged daily, and afterward well rubbed and dried, so as to cause a glow on the surface. In some cases, salt and water, or vinegar and water, are preferable, and then much friction is not necessary. The best time for sponging is immediately on getting out of bed in the morning, when there is no perspiration. The effect is nearly similar to that of the shower bath, rendering the habit less susceptible of cold; and, when followed by exercise in the open air and proper regimen, increasing the appetite and digestion. Sponging with this view is said to be as efficacious as the shower bath, and is more proper for delicate habits. *Fig.* 914 is a shallow vessel used for sponging; and to prevent taking cold during the operation, it may be performed under a loose dressing-gown.

Fig. 914.



SUBSECT. 8.—*Warm Bath.*

7082. This strictly includes the warm water, vapour, and air bath, but the effects of these are different, and we shall first consider the warm-water bath. The effects vary with the temperature, which ranges from 92° to 98°. When the heat is about 92°, though the first effect is slightly stimulating, yet, when time is given for that influence to subside, it is gradually succeeded by soothed and tranquillized sensations, which generally allay slight degrees of local irritation of the nervous system. At a higher temperature, but under 96°, it has sometimes been imagined that the warm bath relaxes and weakens, whereas it produces a contrary effect; it is found to raise the spirits, to mend the pulse and appetite, and to refresh and invigorate the whole frame. In consequence of its soothing and agreeable impressions on the surface of the body, it produces very beneficial effects in certain disordered states of the alimentary canal originating in diminished action; but if the heat is considerably greater, or above 98°, the feelings are even painfully excited, and the temporary stimulus is followed by a proportionate degree of exhaustion. The warm bath modifies the texture of the skin; it increases the frequency of the pulse, and excites the superficial capillaries to increased action, and it also equalizes the circulation of the blood. By relieving pain and irritation, it acts as a sedative, and, by restoring deranged functions, it is an indirect tonic. The warm bath is seldom necessary, or taken, in perfect health, but it is very beneficial after fatigue or muscular exertion: in these cases the body should be allowed to rest and cool before the bath is taken. It is an invaluable remedy after travelling, which with persons of delicate or feverish habits, even in the easiest carriage, for several successive days, is apt to produce defective secretions, and general irritation of the nervous system, more particularly if there be any tendency to chronic inflammation. It is likewise useful after long mental excitement, from whatever cause, and in a variety of slight disorders of the system, such as nervous and spasmodic affections. It is effective in softening the skin, and enabling one to detach the scales which are on the surface in a state of partial decomposition, by which the function of perspiration becomes freer, and hence it is often beneficial even to the healthful.

7083. When the body is immersed in the warm bath, an agreeable sensation of warmth is perceived, the veins on the surface swell, the bulk of the body is increased a little, and the skin becomes redder than usual; the action of the heart is increased, and of course the pulse is quickened. In cases of disease, the warm bath should never be employed, except by the advice of the medical practitioner. It is perilous to persons of full habit, who are liable to a flow of blood to the head, which the warm bath promotes. When used for the preservation of health alone, the salt-water warm bath is preferable to the fresh. In a warm bath it is essential that the original temperature, whatever that may be, should be kept up the whole time that the patient remains in the bath; the temperature is best ascertained by the thermometer, of which a kind is made for this purpose.

7084. *The time of immersion in the warm bath* should be varied according to the temperature of the water and the feelings of the patient. In a bath of 94° to 96°, a person may remain fifteen, twenty, or thirty minutes; much longer time will prove relaxing: many persons prefer 95° or 96°; few lower than 93°. In a bath of 98°, or more, it will not be proper to remain so long, and, indeed, there are few persons that can bear to remain beyond ten minutes, and, in the generality of cases, not so long. Persons labouring under chronic rheumatism or palsy bear the highest degree of temperature best: these often require the hot bath. When sweating is desired (which will seldom happen except in cases of local inflammation), the warm bath should be used in the evening, and the patient should be immediately afterward put into a warm bed, and remain there until late in the next morning; but in all other cases where perspiration is not required, or in which it would be hurtful, the best time for using the warm bath is in the forenoon, about two hours after breakfast. In this case the bathers should not retire to bed, and it is not absolutely necessary to confine themselves within doors; but if the weather is cold, it will be prudent not to go immediately into the open air, but to remain quietly in the house for an hour after the bath.

7085. *Springs of water, in a state of nature*, are found at various degrees of temperature, even boiling; some of them, when of a moderate temperature, constitute warm and hot baths. In this country the only natural warm spring is that of Bath, the temperature of which is from 96° to 106°, although the water issues from the spring at 116°: on the Continent there are many warm and hot springs; those of Vichy and Barège are 120°; of Borset, 132°; of Aix-la-Chapelle, 143°; and Carlsbad, 165°.

7086. *With respect to the form of the bath*, though the common portable bath answers every purpose for which the bath is usually administered, yet in some cases, particularly when the stay in the bath is prolonged, a large open bath is much to be preferred, as the constrained position in a small bath cannot be borne long. Indeed, Bath is the only place in England where the warm bath can be taken with the greatest benefit. Our usual warm baths are necessarily artificial, and are to be found in the public establishments for the purpose. Besides these, there are portable baths, of the full size, sold by ironmongers, of tin plate painted, and of copper, as *fig*. 910.

7087. *Fig*. 910 represents one of these baths, with a fire and flues beneath to heat the water. It is scarcely necessary to observe that the bath must be placed near the chimney, that the smoke-pipe may go into the chimney-flue. The convenience of this construction of bath is very great, the labour of filling a bath with warm water being considerable.

7088. *The hip bath*, *fig*. 915, is fitted to receive the hips only, and to affect those organs that are contained within the pelvis. It has the advantage of requiring very little water, as the bulk of the part immersed raises the water on each side so as to cover the hips, and it is sloped so as to afford a support to the back. In using it a pillow or blanket should be placed on the slope.

Fig. 915.

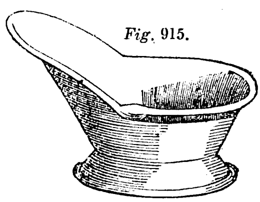


Fig. 916.

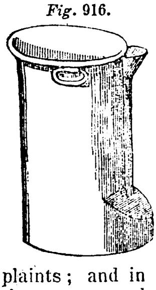
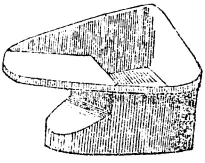


7089. *The leg bath*, *fig*. 916, should be deep enough to allow the water to rise as high as the knee. The projection at the bottom is to permit the foot to find room without increasing the diameter of the upper part.

7090. *The foot bath* is generally an oval pan of tin or earthen-ware, of sufficient size to admit the feet with ease. *Fig*. 917 is an improved kind, with a rest for the foot in drying it. After getting the feet wet, plunging them into warm water will often prevent any ill consequences; and this is found of great service in the chill and slight shivering which usher in colds, fevers, and other inflammatory complaints; and in inflammatory diseases, where the head and throat are much affected, the employment of a foot bath at a later period often gives great relief, by causing a revulsion of blood from the upper to the lower part of the body.

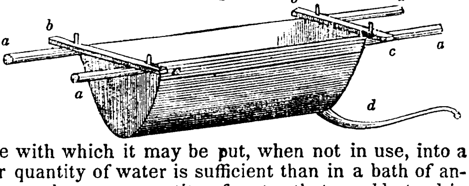
Fig. 917.



The warm douche bath has been already mentioned, p. 1192.

7091. *Dr. A. Thomson's portable bath* consists of a piece of water-proof cloth made up into the form of a sailor's hammock (*fig*. 918), and kept extended by two long poles, *a a*, *a a*, passed through a broad hem on each side of the hammock, and also by two other cross pieces of wood, *b c*, *b c*, fixed to the long poles by thumb-screws. The apparatus is supported by placing the long poles on two tressels or chairs. The advantage of this contrivance, besides its portability, and the ease with which it may be put, when not in use, into a convenient place, is, that a smaller quantity of water is sufficient than in a bath of another form; the bottom being narrow, the same quantity of water that would stand in height in an ordinary bath only three inches, is sufficient to cover the whole body of the bather. The water is drawn off by a hose or flexible tube, *d*.

Fig. 918.



SUBSECT. 9.—*Vapour Bath.*

7092. The vapour bath is more powerful than the warm-water bath in exciting perspiration, and is often very efficacious in cases of gout and rheumatism, and likewise in stiffness of the joints; also in diseases affecting the skin, in nervous complaints, dry catarrh, and recent affections of the lungs, provided there be no active inflammation. If employed in time, it is found to ward off the bad effects of exposure to cold; but it is improper for persons in a state of great debility. The vapour is certainly the most complete as the means of purifying the skin, combining the full effects of transpiration and opening the pores with ample lavation afterward; yet it exerts so powerful an agency on the system as to be actually injurious and debilitating when frequently used. The Turkish baths, which have been freequently described by travellers, possess a completeness and luxury unknown elsewhere; but they prove enervating, and are said to produce early senility. In this country the vapour bath is seldom used except medicinally.

7093. *Warm and vapour baths have been used* from time immemorial, either for purposes of hygiene, of luxury, or as remedial. By the Eastern nations, in warm climates, they were, and still are, in high esteem; and, as a means of preserving health, were wisely enjoined by the laws of Moses and of Mohammed. Among the Greeks and Romans, who wore sandals and woollen garments, the use of the bath for mere ablution was more necessary than with the moderns, who practise a frequent change of linen; and the magnificence and luxury of the public baths of Thermæ, and even of the private baths of Rome, are attested by ancient authors, as well as by the ruins that remain of the baths. A description of these ancient baths may be seen in Vol. II., "Pompeii," published by the Society for the Diffusion of Useful Knowledge. Traces still remain at Bath, and other parts of England, of such baths, on a similar construction, erected by the Roman colonies in Britain. In modern Europe the use of baths in general, and in particular that of warm baths, had declined and almost become extinct, though it has of late been partially revived. Turkey and Russia form exceptions: in these countries the vapour bath is still used nearly in the ancient manner, and in Petersburgh the baths are on a scale of great magnificence; there almost every one, poor and rich, bathe at least once a week.

7094. *There are two principal forms of the vapour bath:* 1. The free vapour bath, or steam chamber, as employed in Turkey, the Eastern countries, and in Russia; 2. The confined or solitary vapour bath, as commonly used in this country. The first consists of a close room filled with vapour from water at a temperature varying from 160° to 180°, in which the bathers move about at pleasure. In these chambers there are benches along the walls, arranged so as to rise one above the other as in an amphitheatre, on which the bathers sit, the heat being greatest on the uppermost seat. The vapour, or steam, is produced by throwing water from time to time on red-hot stones. The bathers first enter an anteroom, in which they undress. On coming into the bath, they take their places first on the lowest benches, and move to the higher, according to the length of their stay. During the time of their remaining in this bath the body is gently beaten with fresh birch twigs, and *shampooed*, by having the muscles gently pressed and kneaded; they are likewise rubbed with soap-suds, wheaten bran, &c. Cold water is also thrown upon the body by a douche tube. After being thus operated upon in various ways in the vapour by the attendants, they retire to another apartment containing only warm air, where they put on a flannel dress, and having drunk some warm fluid, they lie down to perspire; after sufficient time, they return to the anteroom, and dress. It is a remarkable fact that the Russians, after having been subjected to the influence of the vapour bath, on coming out expose themselves fearlessly to the cold, and even plunge into the snow without injury, which is supposed to restore the tone of the skin that had been relaxed by the hot vapour.

7095. A very simple kind of vapour bath, nearly resembling that used by the Hindoos, is common in this country. The patient is seated naked on a chair, *a*, *fig.* 919, and a vessel full of boiling water is placed at his side; a large blanket is thrown over his body and head, together with the vessel of hot water: this confines the vapour that rises from the latter when the vapour is to be breathed, or it is turned under his chin when it is not to be breathed. Perspiration is soon induced, and if it be necessary to keep up the action of the bath for any length of time, this may be done by dropping into the water bricks heated in the fire.

7096. A more elegant apparatus is formed by having a small steam boiler, *b*, *fig.* 919, placed so that the smoke may be conveyed by an iron pipe into the chimney-flue. The boiler must be furnished with a safety-valve, and the fire is made below it; a small tube with joints, *c*, conveys the steam to the patient; and a basket, *d*, is fixed at the top of the chair to give room for the patient's head, and prevent the blanket from collapsing. In some public bathing establishments a vapour bath is formed on a larger scale, and is supplied with steam from a boiler in another apartment. Besides artificial vapour baths, there are natural ones in several parts of the Neapolitan states, Ischia, and Switzerland.

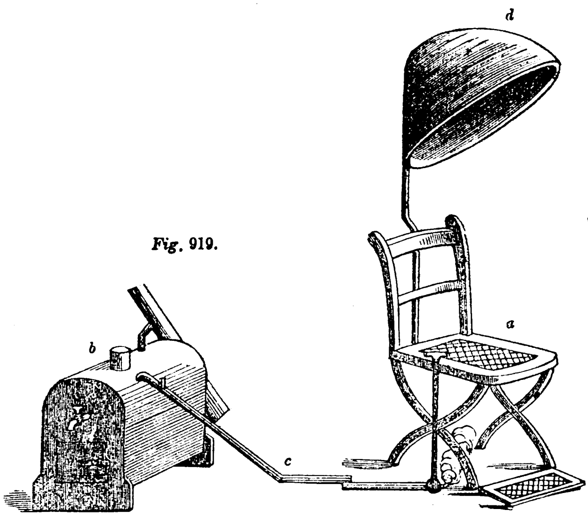


Fig. 919.

7097. *Various establishments of baths in London* are well known, and where almost all the modes of bathing may now be employed at a reasonable expense: we shall only particularize two, one belonging to the "Royal Portable Bath Company," in Oxford-street, from which warm water and a bath are sent to any part of London in the manner practised at Vienna, Baden, and other cities on the Continent; another is the Oxford and Cambridge baths in the Edgeware Road, where vapour baths are sent out. Various public large swimming baths have likewise been lately established; but this subject is beyond our limits.

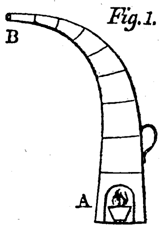
Subsect. 10.—*Warm-air Bath.*

7098. Common air, above the temperature of the body in a state of health, has been used as a kind of bath in particular cases. Warm-air chambers were employed even as luxuries by persons in health among the ancient Romans, and in Russia they are now occasionally used previous to the vapour bath. Its effect is to produce perspiration, which it does more rapidly than even the vapour bath, to which its operation is very analogous, though it differs from that in producing all its stimulating without its relaxing and soothing effects. Like the vapour bath, it is of two kinds, according as the warm air is breathed or not breathed. The latter mode is now commonly practised.

7099. The most convenient kind of warm-air bath is that introduced by Dr. Gower in 1819, under the name of *Sudatorium.* This acts upon a part of the body only. The apparatus consists of a semi-cylindrical frame-work, or oblong arch of wicker covered with blankets, and laid over a part of the patient in bed. The air is heated by means of a lamp connected with the apparatus, and may be raised to different degrees of temperature as may be required. It does not appear to be necessary to have a high degree of heat; air heated to 85°, or from that to 90°, produces, in general, a profuse perspiration, and has been found to relieve greatly in chronic rheumatism, and other pains and stiffness of the joints; also in various diseases of the skin, and in fevers. Some physicians speak in terms of high approbation of its advantages, but it is seldom employed, and it would not be advisable to try it, except under the direction of a medical practitioner. In very low constitutions of the habit, hot air above 100° may be productive of great mischief.

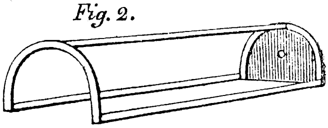
[The merit of the invention, here ascribed to Dr. Gower in 1819, is due to Dr. Samuel K. Jennings, formerly a practitioner in Virginia, but since a Professor in the Washington University of Baltimore. Many years before 1819, under the name of Jennings's vapour bath, this "Sudatorium" was employed as a domestic remedy very extensively in the southern states, and there can be little doubt, from the identity of the apparatus described as Dr. Gower's, that his knowledge of it was obtained in some way from the patent office of the United States, where Dr. Jennings had filed both a model and drawings, with the view of securing the proper application of the remedy, and preventing the indiscriminate use which might bring it into disrepute. Moreover, he had published, as early as 1818, a pamphlet on the importance of the skin, as a means of diagnosis in pathological investigations, and the value of heat externally applied as a therapeutic agent, which pamphlet had an extensive circulation, and will be found to anticipate this invention of Dr. Gower. For convenience in applying the warm-air bath where this is indicated, as it often is, in chronic diseases, Dr. Jennings's invention cannot be surpassed.

Fig. 1.



The apparatus, in its simplest form, consists of two parts, viz., *fig.* 1, a cylindrical tube of tin, sheet iron, or copper, about four inches wide at the bottom, A, and tapering until it is only one inch in diameter at the top, B. This constitutes the stove, a window being placed at the bottom, A, within which stands a small moveable cup, which, being filled with alcohol, is set on fire, the heated air then rises and passes through the stove, while the vapour of the alcohol is condensed or diffused as the operation goes on.

Fig. 2.



In *fig.* 2 is shown the semi-cylindrical frame-work, which, being placed over the body of the patient in bed, sustains the weight of the superincumbent blankets, quilt, &c. The small end of the stove-pipe being inserted into an opening seen in the closed end of the frame-work, and the alcohol inflamed below, the heated air soon surrounds the body, and speedily produces a general and profuse perspiration, which being effected, the stove is taken away, and the frame-work is drawn out from the foot of the bed, leaving the patient beneath the clothes as long as it may be desirable to keep up the perspiration.]

Subsect. 11.—*Hot Bath.*

7100. *The hot bath has a temperature* from 98° to about 112°, or the greatest heat that can be borne. It is a powerful stimulant, and should never be used by persons in a state of perfect health, but is employed only in cases of disease, and this should always be under the direction of a medical practitioner. As the object is to rouse the nervous and the general vital action, the bather should never remain long enough in the hot bath to produce exhaustion; the average time for using it is from ten to fifteen minutes. The few cases to which the hot bath is suited are chronic affections of the nervous system, such as paralysis, when all vascular fulness of the brain has been removed. The waters of the King's Bath, at Bath, and some of the hot baths on the Continent, are beneficially employed in such cases.

Subsect. 12.—*Medicated Baths.*

7101. Medicated baths are those in which medicinal substances are added to the medium of the bath. Some of these are very efficacious in certain diseases, but their use is very limited. *Sulphurous vapour baths* are found useful in several diseases affecting the skin. The *nitro-muriatic bath* of Scott is serviceable in chronic inflammation of the liver contracted in warm climates. The *ferruginous baths* in Nassau and the Hartz are more tonic than the simple cold-water bath. Many others occur in different parts of the world, but are little known, as the mud baths of the Italians; and there are various baths of mineral waters, some of which are highly praised. Carbonic acid gas issuing from the interior of the earth has been applied to the formation of air baths at Marienberg in Germany, and found useful as a powerful sedative. But the description of these various baths, however important under the direction of a skilful physician, does not come within the limits of a work treating only on domestic economy.

Subsect. 13.—*Sea Bathing.*

7102. Although the most important effects produced by bathing depend upon the temperature of the water, yet there can be no doubt that the effect of simple fresh water and that of the sea are very different. When the object is to produce reaction, and to stimulate and brace the system, sea water, which is the form of cold bath in most general use in this country, is to be preferred. When a tonic effect is required, the water of the open sea is more bracing than that in a confined apartment. Of all the substitutes for the open sea, the *swimming baths*, such as that at Brighton, are the best; and they have this advantage, that they are accessible in every kind of weather, and at any time of the day.

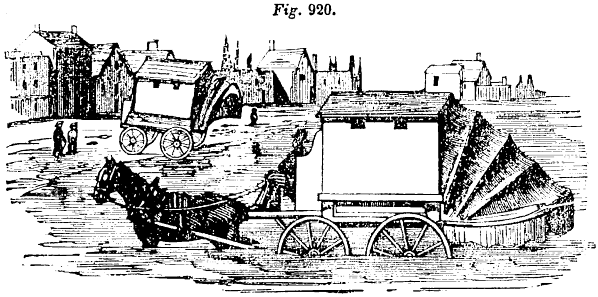
7103. *The manner of going into the bath*, and the time of remaining in it, must depend upon circumstances, chiefly on the condition of the bather. Some plunge at once, in order to have the full advantage of the shock; others, again, are recommended to take at first only one or two dips, to ascertain the power of reaction, and gradually to prolong the stay in the water. Moving the body and limbs while in the water is highly advisable, and the exercise of swimming is good, if the patient has sufficient skill and power. The body should be quickly and well rubbed, and dried with a somewhat coarse towel, and the clothes put on without any unnecessary delay; though this precaution is not so necessary as in bathing in fresh water, as the particles of salt that remain in the skin after evaporation stimulate it more than rubbing. A common error in the practice of sea bathing is, that the patient remains so long in the water that the animal heat is lowered below the proper degree, and the consequence is a subsequent sense of chilliness that is injurious.

7104. *It is recommended that the invalid should take some gentle exercise* previous to going into the cold bath, with the view of rendering the circulation more vigorous, but not so much so as to induce fatigue, or much perspiration. It is not proper to enter the water with the slightest sense of coldness.

7105. *When the bather is in delicate health,* the temperature of the water is an important consideration. In that case, from 11 to 12, after breakfast, may be preferable to the early morning; but in some parts of our southern shores, sheltered by high cliffs, the sun is too powerful in the middle of the day for invalids, and then an earlier hour may be more suitable. It is often a common error, but one oftener committed by those who bathe for laxing than by invalids, that they remain so long in the water that the animal heat is lowered below the proper degree: to boys of a feeble constitution the mischief from this is considerable. In order to obtain the full degree of salutary reaction, immersion in the cold bath should cease just before the temperature of the body is sensibly diminished; and a proof that this point has not been passed will be, that the glow or reaction is felt to continue.

7106. *Fig.* 920 is one of the bathing machines now so common at all our watering-places. It consists of a small wooden house placed upon four wheels, drawn by a horse,

Fig. 920.



the driver sitting in front. At the back there is a set of large semicircular hoops, having canvass stretched over them that can be lowered by means of hinges into the position represented in the cut. Within the area enclosed by this canvass there are steps from the back of the machine, by which the bather can descend from the interior into the sea without being seen from the shore. When the machine is not in use, these hoops are drawn up, as in the machine represented in the distance.

7107. *The periods of the year* best adapted for sea bathing are the summer and autumn, when the temperature of the water on our shores varies from 55° to 70°. Those who have vigorous constitutions, or, at least, great powers of reaction, may continue to bathe in the sea beyond the autumnal months, and some even in winter; but it will scarcely ever be proper to commence bathing at the latter time.

7108. *The time of day for bathing in the sea* must depend partly upon the locality and state of the tide; but, independently of these considerations, the best time, either as a measure of hygiene or as a remedy, will be about noon, that is, two or three hours after breakfast, when the system is sufficiently recruited by the morning's meal; but should the sun be very powerful at this time, an earlier hour must be chosen. When the constitution is strong, the temperature of the surface high, and the person refreshed and active when he rises from his bed, the bath may be taken before breakfast. The temperature of the water on the seashore will vary with the locality, the hour of the day, and the time of high water. If the shore consist of level sand or shingle, the tide which flows in the afternoon over a large expanse of surface is somewhat heated.

7109. *In cases of relaxed habits,* when there is a tendency to perspiration on slight exertion, or to cold, clammy perspiration in bed, the salt-water bath proves eminently useful, particularly when combined with dry, pure air and a bracing climate, such as are found on the airy downs along the southern shores of our island. It acts as a preventive of the numerous family of catarrhal diseases which are the result of debility, and it strengthens in a peculiar manner the skin and mucous membranes of the air-passages, the relaxation of which is so productive of catarrh on the least change of temperature. With this view, sea bathing should be practised for some time during the summer season, and afterward the shower bath; during the winter it will be proper to employ sponging on the chest and trunk. When considerable irritability of the system is shown by the state of the mental functions and the hypochondriasis of literary persons, cold sea bathing is particularly useful; but in a state of actual indigestion, especially if complicated with sub-acute inflammation of the mucous membranes of the stomach or intestines, cold bathing is very injurious. It is serviceable in cases of torpor and loss of power, and in weakness of the limbs, and after spasms and paralysis.

Simple as the cold bath appears, yet, like all other remedies, it requires caution; in infancy and old age it is less admissible than at other times, and it is quite improper if the debility is great; and hence, previous to entering upon a course of sea bathing, it is prudent to consult a physician resident upon the spot.

7110. *Warm Salt-water Bath.*—Saline impregnations modify the effects of the warm bath. The warm salt-water bath is sensibly more stimulating than the warm bath of fresh water. Accordingly, to those who are strong, after fatigue, much more refreshment is conveyed by a warm sea bath than by an ordinary warm bath; and many of those who are of that exhausted habit that they would be enfeebled by the latter, take the former with benefit and sensible improvement of strength; hence some of the contradictory accounts sometimes given of the effects of warm bathing. Baths with saline impregnations can be borne for a longer period, and are followed by less exhaustion, than those of pure water, and patients are less liable to take cold after the former.

Sect. VI.—air.

7111. The subject of the necessity of breathing good air has been already treated of in Book III., "On Ventilation." We may here state that the air is chiefly contaminated by exhalations from decomposing animal and vegetable substances: the exhalations from animal matters are most abundant in towns, particularly in large manufacturing towns, where there are numerous poor; in such places not only are the habitations uncleanly, but the system of sewerage is imperfect; matters are left to accumulate, instead of being carried off, and poured out into rivers or reservoirs; large dunghills are sometimes seen, on which all the refuse of a neighbourhood is thrown; or, if there be drains, they are uncovered, and their contents stagnate from want of sufficient stream to carry them away. Such a state of things renders those exposed to the effluvia liable to dysentery, diarrhœa, and other bowel complaints; it produces fever, or, at any rate, it aggravates this when present; and, by depressing the general health, it renders all complaints more severe and fatal. In districts in which drainage is very imperfect fever is seldom or never absent, and at particular seasons it rages like a pestilence. These matters have lately occupied much of public attention, and will doubtless soon be remedied; the knowledge of them, however, and the necessity of reform, cannot be too widely diffused.

7112. *The exhalations from decomposing vegetable substances* are evidenced in the effluvia from marshes: they produce agues and remittent fever. It is necessary for the decomposition of plants that there should be a certain degree of moisture, heat, and, of course, atmospheric air; if there be too much moisture, decomposition cannot occur; and very wet places are not so liable to ague as places sometimes wet and sometimes dry: for example, a place in which ague prevails will become free from this when a marsh is converted into a lake; again, a certain degree of moisture is necessary to produce the malaria; and if this be lessened by draining the marsh, agues cease, as in the former case.

7113. *The effluvia from plants* is most abundant in spring and autumn, and for this reason: towards the end of summer plants lose their foliage and their flowers, and scatter their seeds; an immense quantity of dead vegetable matter is thus distributed on the ground; and if the requisite degree of moisture be present, the heats of autumn soon cause decay, and extricate the peculiar substances which produce ague when distributed through the air. Marshes, again, towards the end of summer have lost much water by evaporation, and the water plants which grow in most marshes in prodigious quantity are in a position the most favourable for decomposition. The extrication goes on all the autumn, but is arrested by the frosts of winter, which congeal the water and render decay impossible; but in the spring, when the sun again acquires power, the remnants of the vegetable matter which have escaped decomposition the previous autumn, and which have lain dormant all the winter, are speedily acted upon, and a great quantity of miasma is evolved. When marshes existed over large districts, all complaints were aggravated at these times; and even now it is not uncommon in country places to hear poor people anticipating an increase of their complaints "at the spring or fall of the leaf."

7114. The "*malaria*" is rather peculiar in its transmission; sometimes it is conveyed great distances, at other times it infects only a limited district. In all marshy countries, as a general rule, it is more liable to attack those who are nearest to the marsh; sometimes, however, it will pass over a particular village, and this may sometimes be traced to the presence of woods and foliage between the marsh and village; for it is singular that thick foliage seems occasionally sufficient to arrest its course.

Malaria is more liable to attack new comers, and those unused to it, than inhabitants of fenny countries; it will sometimes not excite ague till the strength of the individual has been accidentally lowered by some cause or other. It seems more powerful in the evening than in the middle of the day; it will attack those sleeping on the ground floor, and pass over those who are at the top of the house; sleeping on the ground in the open air is almost sure to give an attack.

7115. Touching the means of preventing the action of malaria, some have fancied that smoking has much power as a securitive; and in fenny countries some people al ways take spirits before going into the air in the evening; but it is doubtful if these do any good: the best thing is to take two or three grains of *sulphate of quinine* every four or six hours, directly any symptoms of an attack are perceived.

SECT. VII.—TEMPERATURE.

7116. The human frame is capable of a considerable power of accommodation, and can sustain without inconvenience the extremes of temperature: as a means of preserving health, however, a temperature moderate, and not suddenly changeable, is the best; but on this subject we refer the reader to what we have said on "Warming," Book II., and "Ventilation," Book III.

SECT. VIII.—EXERCISE.

7117. Exercise is absolutely necessary to preserve the health; most people will admit this statement, but few know exactly what proper exercise is: by proper exercise is meant the use of all the muscles in the body, not in an immoderate degree, but enough to keep them in full play, and render the discharge of their office easy and pleasant to the person; hardly any kind of exercise by itself can be considered as doing this; even walking, which is, on the whole, the best, exercises the legs much more than the arms, and with walking it is necessary to combine some plan by which we may call into play the muscles of the arms and of the chest: the legs of the professional pedestrian are often beautifully developed, while his arms appear as if made for another person: the arms of the blacksmith, again, are those of a powerful athletic man, while his legs are comparatively small and feeble. Therefore walking, by itself, although extremely useful, does not answer to the definition of *complete* exercise, unless it be combined with the use of the dumb-bells, or with some plan which enlarges the chest and calls into action the muscles of the upper half of the body.

7118. Boating and rowing, again, exercise the chest and arms more than other parts, and in moderation, and combined with walking, no exercise is better than rowing; but if too much indulged in, it is apt to supersede walking, and then the arms are immoderately used; and, from the constant moving of the chest, the heart is made to beat stronger than it should, becomes over-nourished, and at length enlarged, and then perhaps diseased in other ways.

7119. Horse exercise is very good, and in some particular cases remarkably useful, but, like every single form of exercise, it is too partial in its operation, calling into play only a few, comparatively, of the muscles in the body; it should consequently be combined with walking, the use of the dumb-bells, &c.

7120. Carriage exercise is useful chiefly by the fresh air, change of scene, &c., which accompany it.

Among other exercises, particularly in those predisposed to any diseases of the chest, reading aloud is one of the best that can be taken; it calls into play many muscles, and causes a more rapid transmission of the blood through the lungs.

7121. To sum up what we have said in a few words, exercise must be composite; walking must be combined with other forms; horse exercise must not alone be depended on; one set of muscles must not be exercised to the exclusion of other sets.

7122. With regard to the degree and extent of exercise, this must be left to the discretion of each individual. We may make this remark, that great exercise must not be taken *suddenly*, that is to say, a person who for some months has not been able to exercise regularly must not attempt at once to return to the same degree he used before the disuse; he must regain the standard gradually. *Excess* of exercise is indeed very hurtful; many diseases, particularly of the lungs and heart, are brought on by it; the violent rowing which is practised at some of our universities has in several instances been attended with very disastrous consequences.

[The observations of this section are judicious, but incomplete Exercise, to be useful, should be performed in the open air, and it is for this reason that the use of the dumb-bells is not adequate of itself to secure the objects of an invalid. The same objection lies to a reliance upon dancing, since this, also, is mostly performed within doors. Sawing wood for males, and jumping the rope for females, in the open air, when the weather permits, will be found the preferable modes of exercise, calling into action all the muscles of the body, and especially those of the arms and chest.

Invalids should, whenever practicable, be advised to select modes of exercise which are somewhat in the nature of productive labour. To exercise for any length of time merely for the sake of health is found to become a daily toil; while labour in the agricultural or mechanic arts may be made productive, at least in seeing the fruits of their work, and calls off the mind from the existing disease which renders exercise necessary as a remedial agent. Hence those who travel solely for health, having no definite object in view, are seldom benefited by the exercise of riding or sailing, because the mind, instead of being employed on the changing scenery and varied objects of contemplation, reacts upon itself, and pores over the morbid symptoms which impose the journeying as a task, often when rest would be preferred. To have in view some object of business or even to visit distant relatives or friends, should be secured whenever practicable, in order to secure the full advantages of exercise when medically advised.]

CHAPTER IV.

USEFUL INFORMATION IN CASE OF SICKNESS IN THE FAMILY.

7123. Under this head we propose, *first*, to describe some slight disorders which are usually curable without medical aid; *secondly*, to enumerate the circumstances which would lead us to apprehend the approach of certain severe diseases; *thirdly*, to notice the chief accidents which may occur in a family; and, *fourthly*, to detail the management of the sick-room during the prevalence of certain severe affections. The two latter we shall treat of in separate chapters.

SECT. I.—SLIGHT DISORDERS USUALLY CURABLE WITHOUT MEDICAL AID.

SUBSECT. 1.—*Common Cold, Cough.*

7124. *A cold begins* with a little chilliness, and feeling of illness, followed by slight pains in the back of the head, down the neck, or in the back; there is often headache; the nostrils seem dry and stuffed; there is frequent sneezing, and soon afterward discharges from the nose and eyes. Such an attack is often called "a cold in the head;" after remaining at a height for two or three days, or longer in some individuals, these symptoms gradually subside, leaving behind them a little hacking cough with slight expectoration, which continues for two or three weeks.

Treatment of a Cold.—Almost every one possesses some way of curing his own cold. In most cases it is advisable to keep within doors, to take care of draughts, and to leave off animal food for two or three days; the feet may be bathed in warm water, and a pill taken, consisting of a mixture of blue pill (about two grains) and James's powder (about three grains).

If the cold be very severe, if there be considerable fever present, indicated by a hot skin, quick pulse, furred tongue, and thirst, the patient should retire to bed; a brisk aperient should be taken, and at night the warm foot bath used, and the pill above mentioned. After two or three days the violence of the cold subsides, and the cough left is often troublesome: the following draught is useful:

Take of wine of ipecacuanha, 10 or 15 drops; camphorated tincture of opium, 20 drops; camphor mixture, 3 table-spoonfuls. *Draught to be taken night and morning.*

Or this draught is often efficacious, viz.:

Take of tincture of balsam of tolu, 20 drops; compound powder of ipecacuanha, 5 grains; mucilage of acacia as much as may be sufficient; water, 2 table-spoonfuls. Draught to be taken every night for 3 nights running.

For measuring the drops, it is advisable to use a little graduated glass called a *minim* measure, and which can be bought at any druggist's shop. Sometimes a cold is arrested by a plan altogether the reverse of this, viz., eating as usual, and taking a glass or two of wine more than ordinary; and this plan is chiefly successful when there is but little feverishness attending the cold. Another plan by which a cold can sometimes be at once arrested is, taking a dose of tincture of opium (about twenty minims of the tincture) at bedtime, and following it up next morning with an aperient mixture, such as the following:

Take of sulphate of magnesia (Epsom salts) from 2 to 4 drachms; infusion of senna, 3 table-spoonfuls; tincture of senna, 1 drachm (60 minims). Draught to be taken the first thing in the morning.

However, if this plan do not stop the cold, it will increase it; and we do not recommend it unless there be some particular necessity for speedily getting rid of the cold. Another plan has been much recommended by Dr. C. J. B. Williams, and which seems really to be beneficial, particularly in cases where colds are very severe, lasting for 2 or 3 weeks; we allude to the total abstinence from fluids of all kinds for 48 or 60 hours; the lips may be wetted, but no fluid should be swallowed. In 46 or 48 hours the severe symptoms disappear, the eyes no longer smart, the discharges from the nose cease, and the cough disappears; one great advantage of the plan is, that it permits the individual to pursue his ordinary avocations; it does not confine him to the house. But this plan greatly augments fever when it is present.

SUBSECT. 2.—*Influenza.*

7125. This in many respects resembles a severe cold, but with more fever, with greater headache and loss of appetite; the cough is also often very severe, and there is a remarkable loss of strength; the general indisposition is very distressing; there is great thirst, white tongue, with heat of skin and quickened pulse.

7126. *Treatment.*—This is a much more serious complaint than cold, and almost always demands medical aid: the warm bath should be used, and the patient should go to bed, and take the pill formerly mentioned (viz., blue pill and James's powder), and next morning an aperient; if senna be very disagreeable, Epsom salts may be taken in an effervescing draught.

SUBSECT. 3.—*Sore Throat.*

7127. This often accompanies a cold. In a severe form it requires medical attendance; when not so severe, however, it is often relieved by simple gargles, such as solution of gum, with barley water, and by the inhalation of warm, watery vapour.

Individuals are sometimes annoyed with constant recurrences of sore throat. When examined, the throat is seen swollen, but not very red; in fact, it is what is commonly called relaxed sore throat: now it is in these cases that gargles of capsicum and of port wine are useful, but it should be remembered that these gargles, if there be much inflammation, are likely to do more harm than good; and, instead of them, we beg to recommend a gargle of alum directly the soreness and feeling of relaxation begin to appear. This gargle must be saturated with alum, and is best made in the following manner: A piece of alum is pounded finely in a mortar, and then boiling water poured upon this, and rubbed with the alum; or the alum, when powdered, may be put out of the mortar into a glass, and boiling water poured upon it, and the two stirred together with a spoon; then the water must be poured off and left to cool; if any alum is deposited as it cools, it proves that the solution is saturated. The gargle thus prepared should be used every hour or two for several successive times; after the few first times the pain and difficulty of swallowing subside, and gradually altogether disappear.

It is a good plan, when sore throat is a common occurrence, to gargle every morning, or every other morning, with this solution. Solution of salt and water is also a good gargle in such a case.

SUBSECT. 4.—*Stiff Neck.*

7128. A stiff neck is almost always relieved by warm fomentations and the warm bath; warmth may also be applied by means of hot flannels wrapped round the neck. A dose of James's powder (three or four grains) may be taken at bedtime.

SUBSECT. 5.—*Toothache.*

7129. Toothache may be rheumatic, or may be caused by the decay of a tooth and inflammation of its nerve.

In the former case the pain extends to several teeth, and along the jaw; it is duller than the pain of decayed teeth, and does not come on in paroxysms; there are also often pains over the head or down the neck, in fact, rheumatism extending to other parts.

In toothache proceeding from decay the pain is at times dull and gnawing, at times severe and cutting, shooting to the ear, along the jaw, and down the neck: the cause of the pain is an inflammation of the nerve distributed on the pulp of the tooth, and the pain is more or less severe, according to the extent and height of the inflammation. To understand this fully, a few words on the structure of the teeth become necessary. Every one knows that teeth have different shapes: one part is called the body, the other the fang of the tooth; each tooth is composed of a bony matter called the ivory and of a white matter covering this on the crown, very hard and dense, and termed the enamel of the tooth. Within the tooth is a cavity, having somewhat the shape of the tooth itself, and filled with a whitish substance called the pulp; at the end of the fang of the tooth is visible a little opening; into this opening pass numerous little vessels and nerves; they run into the central cavity, and are distributed on the pulp: now when the tooth has decayed somewhat, the food which is taken into the mouth can more easily make an impression upon the nerve; if this impression be sufficiently severe, inflammation follows, and lasts a longer or shorter time.

Several circumstances are at once evident from this statement; it proves how careful everybody should be not to let the teeth decay too far, else it becomes impossible to stop them. The process of stopping consists in scooping out all the decayed part of the tooth, and filling up the hollow with gold leaf or tin foil; if the decay has gone on to near the pulp, there is not sufficient ivory left to be scooped out. Again, it is very evident that the use of dropping laudanum and other sedatives into the tooth results from their action on the nerve itself; laudanum, indeed, is often very successful in alleviating the pain. Besides laudanum, various remedies are applied to a decayed tooth to relieve the pain; *camphorated spirit*, applied on cotton wool, or *creasote*, or *oil of cloves*, are often used with success; these seem to act, not as sedatives, but by exhausting the irritability of the nerves, and then their sensibility being deadened, the pain ceases. It might be expected that we should enlarge here on the subject of dentists, but we think it would be invidious to point out any particular individuals as better than others; and as there are plenty of excellent educated dentists in London and the large provincial towns, it is a man's own fault if he run the hazard of losing his teeth by placing himself in the hands of an empiric. We wish, however, to caution our readers against the use of alloys, amalgams, mineral succedanea, &c., and all the tribe of advertising dentists: some of these substances are made with silver and mercury, and are positively hurtful; others are useless; and though, occasionally, some seem to answer their purpose, the employment of the majority will be attended with disappointment. We believe we may safely add that all the best dentists in London have long given up these compounds. When toothache is very severe and the gum is inflamed, it is often useful to apply one or two leeches to the gum.

SUBSECT. 6.—*Earache.*

7130. This is sometimes merely a nervous affection, and may be relieved by dropping two or three drops of laudanum into the ear, with or without a little sweet oil; but often earache is by no means a trifling affection, and if the laudanum do not relieve the pain, medical assistance should be sought for, as high inflammation may prevail, and hearing may be interfered with—the brain even may be affected; leeches and active treatment, even blood-letting, become necessary.

We take this opportunity of mentioning that in case of any little insects getting into the ear, they will be immediately killed by a few drops of olive oil poured into the ear, if, indeed, the acrid secretions of the passage have not already had that effect. If a child put a seed, a little pebble, or any small body of that nature, into the ear, it may be often extracted by syringing the passage strongly with warm water for some time: if this do not effect its expulsion, the scoop or forceps of the surgeon become necessary.

SUBSECT. 7.—*Headache from Indigestion.*

7131. Headache may arise from numerous causes, with which at present we have nothing to do. We speak now of that kind of headache which people know arises from indigestion; the bowels being a little more costive than usual, the food having been different from the accustomed routine, are circumstances which in particular individuals are often followed by a heavy, tense headache, situated over the eyes, or over one eye and over one temple, or else extending all over the head. There is often a difficulty in casting the eyes up suddenly to the ceiling; the eyes look heavy, and under them is a darkened circle; there is also present a feeling of sickness, uneasiness and weight in the stomach, particularly after meals; the bowels are costive; there is flatulency; the urine is turbid; the tongue is white; the mouth parched or clammy; the breath is often a little fetid, and the food may be tasted for several hours after it has been taken.

7132. *Treatment.*—If there be much nausea, and feeling of weight and distention, an emetic of ipecacuanha becomes necessary. To an adult of twenty years and upward, from fifteen grains to one scruple will be a good dose; for a boy of twelve years, half a scruple will be sufficient. Warm chamomile tea may be drank afterward; it keeps up the sickness, and effectually dislodges all offending matter from the stomach. After the emetic has fully acted, an aperient mixture should be given.

To avoid these headaches, attention to diet and the state of the bowels are the great points to be regarded. The diet should be simple, without fermented liquor; animal food should be taken once a day. To regulate the bowels, nothing is better than dinner pills, containing a little rhubarb, aloes, and compound extract of colocynth; when the bowels are got into a regular state these should be discontinued.

SUBSECT. 8.—*Hysterical Fits and Affections.*

7133. An hysterical fit, although generally a very innocent thing, is sufficiently alarming when seen for the first time. Although most usual in excitable and ill-regulated minds, it may occur in the most sensible and calm-judging person. Sudden shocks, fright, great mental emotion, grief, joy, anger, will produce in any one an hysterical fit of more or less violence.

The fit is often preceded by a feeling of faintness, and of choking, as if a ball were rising in the throat, interfering with swallowing, and even with speech. Then comes on a violent fit of screaming, and sobbing, mingled with wild bursts of laughter; the eyes are closed, the breath is drawn with labour, the face becomes red, and the limbs perhaps convulsed; the throat is grasped violently, or the hair is torn, or the hands or feet are beaten violently against the ground. In fifteen or twenty minutes the fit goes off, and the patient comes to herself, having been unconscious the whole time, or more often retaining a distinct recollection of the occurrences around her, although she may pretend not to do so. During the fit, all that is necessary is to see that the patient does not receive any injury by rolling violently off the bed or sofa. She should be prevented striking and injuring herself, but beyond this there is no reason to employ force to restrain her movements. The sudden dashing of cold water in the face is often of service; some advise salt to be put into the mouth.

If hysteria always assumed this form, it would be a mild and tractable affection, instead of being, as it is, one of the most difficult to treat in the whole range of medicine. But the social position of women diversifies this disease in a hundred different ways. The conventionalities of society; the strife after fashion; the desire of approbation; the intense longing for sympathy; the mortification of failure; the excessive cultivation of the intellect as compared with the physical frame and strength; the excitation of the moral faculties by theatrical exhibitions, and by the innumerable works of imagination which derive their interest from delusive views of life and actual society, all tend to create a struggle and mental contest, which, in the susceptible organization of the educated woman, ends in many instances in one of the numerous forms of hysterical disease.

We make these remarks not in the shape of a crusade against the present system of female education, for this, as far as we know, has improved, and will improve still more; but we wish to point out to the parents of an hysterical patient how valuable, and indeed indispensable, to the medical man is their assistance in the treatment of the complaint. What advantage can medicines give, or the professional attendance for ten minutes a day, if the cause of all the disorder, the important mental process, be left unremedied? If parents will not assist in the treatment of these complaints, the physician cannot restrain them, nor are they "curable by any herbs." The mind must not be left to itself, nor must works of imagination and of absorbing interest be allowed under the idea of amusement. If possible, some pursuit, interesting, yet not exciting, should be inculcated—some plan by which the intellectual and moral faculties are gratified, but not roused into violent and opposing action.

The excitement of mixed society must in many cases be avoided, but the presence of friends is often singularly beneficial, by withdrawing the mind from constant attention to its own thoughts. Too much sympathy must not be given; and, especially in the middle classes, one must guard against that strange fanaticism which, under the semblance of religion, is too frequently an attendant source of hysteria.

Improvement in bodily health will often remove hysterical affections; hence country air, plenty of exercise on foot as well as on horseback, and sea bathing are of essential use. Plain food and warm clothing are also essential.

[Hysteria, as its name implies, is very frequently symptomatic of some irregularity in the function peculiar to the womb, the periodical secretion from that organ being either deficient or in excess; irregular in its recurrence; attended with difficulty and pain; or, as in many cases, morbid in its quality, being rather a discharge of blood than the ordinary flow. To some one of these conditions the severe, protracted, or repeated attacks of hysteria are to be ascribed much oftener than to the mental or moral causes justly named as occasionally productive of the disease. Indeed, many of the mental manifestations of females, which are afflictive to themselves and others, result from physical disease in the reproductive organ, which, at certain periods of life especially, may be regarded as the centre of sympathy, whence a multitude of morbid affections of the nervous system derive their origin. A neglect of recognising the important bearings of this feature in the female economy often results in withholding that sympathetic kindness and physical treatment they need, and a disposition to apply the indefinite term "nervous" to the group of symptoms which, if they do not ultimately prove serious, are for the present the source of much positive suffering.

The counsel of a skilful and experienced physician should always be sought where the earliest domestic remedies fail to relieve the irregularities of females, and especially when hysterical symptoms supervene.]

Subsect. 9.—*Whitlows.*

7134. These are extremely painful affections, arising from the formation of matter under some of the dense structures of the ends of the fingers and thumb. Cold lotions, or a bread poulice, may be applied; but the most effectual, and after a time, if the case be severe, the necessary treatment is, letting out the water with a lancet; and though this little operation is somewhat painful, yet it is much less so than the torment which often attends the disease.

7135. *Severe Whitlow.*—In commencing, laudanum applied constantly by means of a rag dipped in it, and put round the finger, is a good and soothing remedy.

Subsect. 10.—*Boils.*

7136. These are painful swellings of a hard, dense structure, slowly increasing in size, till sometimes they become as large as a pigeon's egg, or larger; after a time matter forms and discharges itself, then the core, as it is vulgarly called, comes away, and the boil heals up. They should be poulticed, and balsam of Peru applied twice a day; when matter forms, the surgeon's lancet will expedite the cure.

Subsect. 11.—*Carbuncle.*

7137. This is a large swelling, occurring chiefly on the back, very painful, and often four or five or more inches in circumference; matter gradually forms and discharges itself by several openings. It is a serious disease, and requires prompt medical aid. Poultices must be applied twice a day. If the patient be old and feeble, the strength must often be supported by animal food, malt liquor, and perhaps wine and Peruvian bark administered.

Subsect. 12.—*Chilblains.*

7138. These generally arise from sudden variation of temperature, particularly in delicate and loosely-clothed children; they are most common on the feet, but may occur on the hands, nose, ears, or other parts of the body. There is a red, painful swelling, which itches very much when in bed; ice or cold water is the best thing, and should be used two or three times a day, or various stimulating applications are resorted to, as camphorated spirits of wine, tincture of myrrh, or spirit of turpentine. The part should be well clothed, and changes of temperature guarded against. If chilblains are not arrested in this way, the red colour becomes blue, and after a time a vesicle rises, which opens, and leaves a sore and painful place. To this a poultice should be applied, or linen rags covered with some simple ointment. If the sore do not improve, certain applications are necessary, but which must not be used without the sanction of the medical attendant.

SUBSECT. 13.—*Piles.*

7139. In many instances this troublesome complaint arises entirely from a want of due attention to the state of the bowels, conjoined with sedentary habits, deficiency of exercise, and over-eating. In many cases the patient receives great relief from gentle exercise on foot and horseback, unless there be so much pain as to render this painful, in which case medical advice is necessary; otherwise inflammation of the parts may ensue, and cause excruciating torment. With regular daily exercise, also, a diet light and digestible must be used, and the bowels kept in a lax and proper state by a mixture of magnesia and sulphur, or a tea-spoonful of the confection of senna, taken every night: if this be not active enough, a drachm of powdered jalap may be added to every ounce of the confection, and a tea-spoonful of this taken. The parts should be well washed once or twice a day with cold water and soap, and afterward an ointment may be applied, made of a drachm or two of powdered gall-nuts, with an ounce of lard or any simple ointment: it is better to begin with a small quantity of gall-nut, and gradually to increase it.

If the confection of senna be not strong enough, half a tea-spoonful of sulphur may be added to every dose. Sometimes, and particularly in sedentary individuals, the lower part of the bowels gets tinged with blood, and relaxed, giving rise to the idea of piles being present; the best treatment is the avoiding constipation by taking the confection of senna mentioned above, and using exercise, gentle at first, and afterward more active.

Respecting the limits of domestic and medical treatment, this must be left to the discretion of each particular person. It is certainly better to be now and then alarmed unnecessarily, than to overlook an important and latent disease: even a common cold, if suffered to run on without checking, brings no inconsiderable evils in its train, and the slightest chilblain, if treated improperly, may become an obstinate and unmanageable sore.

SUBSECT. 14.—*Corns.*

7140. These are chiefly caused by tight shoes; the best plan is to soak the feet in hot water, and then for a corn-cutter, or chiropodist, to cut out the nucleus or core.

SUBSECT. 15.—*Warts.*

7141. These are got rid of in various ways: some tie a thread around their base; but a better plan is to have a piece of thick paper with a hole cut in it the size of the wart; this is put over the wart, and then every morning a drop or two of the strongest acetic acid dropped through the hole upon the wart; if this do not succeed, dropping oil of vitriol (sulphuric acid) in the same way will perhaps answer.

SUBSECT. 16.—*On the Limits of Domestic and Medical Treatment.*

7142. Although disease in many instances cannot be effectually treated without professional assistance, yet the greatest aid in many cases is afforded to the physician by proper apprehension of his treatment, and by judicious fulfilment of his advice: we do not exaggerate when we say that in many severe diseases the prompt and skilful attention of a nurse or mother is of incalculable importance; without it, the best directed efforts of medicine are rendered nugatory; while possessing it, the physician knows that all his endeavours are seconded in the most efficient manner. But this subject will be enlarged upon when we detail the "Management of the Sick-room—Severe Diseases."

SECT. II.—COMMENCEMENT OF CERTAIN SEVERE DISEASES.

7143. It would be of little use to enter upon the detail of all the multitudinous ills which demand medical assistance: we shall select a few of the more important, and bring these only under the attention of the reader.

The commencement of the different *eruptive* fevers (smallpox, scarlatina, measles, &c.) has already been mentioned.

SUBSECT. 1.—*Ague.*

7144. This disease, extremely common in some districts, is scarcely known in others. It is caused by the exhalations of decomposing vegetable substances, and therefore is chiefly witnessed on the borders of marshes and low countries imperfectly drained, or occasionally flooded. In its severe form it is a dangerous disease, as in the fevers of the Campagna of Rome, where a failing civilization has suffered marshes to lie undrained, and have thus produced in modern Italy an intensity of disease unknown in the days of ancient Rome.

The attack of an ague is unfortunately but too well known. At first the patient feels chilly and cold, heavy, and sleepy; then speedily the cold feeling increases, until it becomes intense; the lips and cheeks become blue; the skin becomes rough (goose skin as it is called); rings drop off the fingers, which, as well as the whole body, are shrunk and diminished in size; there is shaking and trembling. After a variable time, the coldness diminishes, and is succeeded by flushes of heat, which speedily become general; the skin is now as hot as it was before cold; the face is red and swollen; the pulse full, quick, with a degree of hardness; the eyes are dry and red; there is often intense headache and pain in the back. These symptoms, having continued at their acme for some time, gradually lessen, the skin becomes moist, and at length there occurs a universal and plentiful perspiration, which reduces the heat of the skin, and, gradually ceasing, leaves the patient free from pain and fever, but languid, inert, incapable of bodily or mental fatigue. Such is a description of a well-marked attack of simple ague; there are numerous variations, which it would be useless to introduce.

The course of an ague is as follows: It has a disposition to return periodically, that is to say, at a determinate period: thus its attack comes on in the morning, and ceases after some hours; but recurs on the following morning at the same hour; then again departs, and again makes its appearance at the same hour on the third day, and so on. Such a disease occurring daily is called, in medical language, a "quotidian ague;" if, instead of returning every day, it comes on every other day, it is a "tertian ague;" and then the attack is usually about noon; if it returns every third day, it is a "quartan ague," and the attack occurs principally towards evening.

7145. *Treatment.*—The treatment of ague is very successful: the influence of *Cinchona bark* has been known for a long time. It is usual now to prescribe, not the bark itself, but its active principle, *quinine*, extracted by chemical agency, and united with *sulphuric acid*, forming the salt called *disulphate of quinine*. The dose of this is from two to eight grains. It should be given between the attacks, in the following form:

Take of the disulphate of quinine, 2 grains; diluted sulphuric acid, 10 minims (or more, if necessary); diluted nitric acid, 5 minims; infusion of roses, 1½ ounces. Make a draught. To be taken every three or four hours.

The attack of ague may sometimes be arrested by giving an emetic. To adults such as the following:

Take of powdered ipecacuanha from 15 to 25 grains. Mix with a little water, and take. For a child, ipecacuanha wine may be given, or 3 or 4 grains of ipecacuanha itself.

Sulphate of quinine being an extremely expensive salt, charitable individuals living in aguish districts are usually anxious to obtain some substitute equally efficacious and less expensive.

The active principle of willow bark, termed by medical men "salicine" (from *Salix*, the botanical name of willow), has been used for this purpose, and may be procured from the London druggists. It has certainly very considerable powers; but, as it is seldom obtained at all pure, its employment has not hitherto been extensive.

Arsenic is another medicine which has a great influence over ague; it forms the chief ingredient in the "tasteless ague drop" of some districts, and has the advantage of being much cheaper than sulphate of quinine. We do not, however, recommend its employment in non-medical hands, as so powerful a remedy may, if overdosed, lead to dangerous consequences. If it be given, it should be in the form of the *Liquor arsenicalis*, or *Fowler's solution*, as it is often termed; and this may be procured from any druggist. Its dose is at first four or six drops; if it cause any pain in the stomach, or sickness, it must be instantly discontinued. When neither cinchona bark nor willow bark can be obtained, as, for instance, when travellers are attacked in out-of-the-way places, other substances must be had recourse to; thus, chamomile flowers, infusion of marsh trefoil, buck-bean, pepper with rum, and the rhizome (underground stem) of the sweet flag (Acarus calamus) have all been celebrated for curing agues, and all seem to possess powers able to do so, though not equal to cinchona bark. It is a good thing to take an emetic about half an hour before the attack comes on, such as ipecacuanha, 20 grains; or sulphate of zinc, 20 grains.

The root of the common Avens (Geum urbanum) also has been used in ague with success; it enters into the composition of the Augsburg beer, which in some parts of Germany is considered a preventive of ague. The root is boiled in water, and three table-spoonfuls of the infusion given every four hours.

Cascarilla bark has also been employed in agues with advantage when cinchona bark could not be got.

SUBSECT. 2.—*Continued Fever.*

7146. This disease has received various names, according to intensity and modifying circumstances; popularly it is often termed *low*, *nervous*, and, in the worst forms, *putrid fever*.

Of all the common diseases, it is at once the most complex to observe and the most difficult to treat.

It has imprinted on it various forms by the season, climate, and epidemic agencies; by habit of body or mode of life; by cleanliness, or the reverse; by good living, or by scarcity of food; by mode of employment and means of subsistence. It is sometimes a mild disease, sometimes most severe and fatal. The early symptoms present to the unpractised eye nothing distinctive. There are at first various feelings of languor, feebleness, and general illness, with cold shiverings, loss of appetite, constipation, and disturbed sleep, and, two or three days afterward, headache, pain in the back, and aching in the limbs. In the course of a day or two, or not for a week, there ensue certain symptoms which are often the first to be observed by the individual himself or his friends; these are nausea and sickness, heat and dryness of skin, great headache, and pain in the limbs, a dry and furred tongue, quick and full pulse, restlessness, and often a great feeling of distress; and with all this often a remarkable trembling, which causes the limbs to shake and totter during walking, and the tongue to quiver when protruded from the mouth.

These symptoms, popularly termed *feverish*, are by no means distinctive; they may accompany almost any acute inflammation, and, though the educated eye of the physician may be able to form a tolerably correct guess as to the nature of the case, we can not expect, by any description, to enable our readers at once to distinguish the disease. We can enable them, however, to determine that they portend the advent of some dangerous disease, for which it is desirable as early as possible to procure medical aid. But before medical aid arrives something can be done; there is great sickness and nausea; an emetic will often remove this, and give a temporary relief. Emetics are of great service; they give present relief, but they also mitigate the disease through all its succeeding stages; that is to say, a fever which, from the violence of its early symptoms, threatened to be severe, after an emetic runs its course mildly.

But then a difficulty arises: an emetic would be very useful in fever; but is the disease, to see which the medical man has been sent for, really fever? May it not be some local inflammation with feverish symptoms, and in which an emetic may do harm? Undoubtedly it may; but against this there is no remedy: the chances must be taken on both sides, and it may be said that even in local inflammation an emetic may be of service if there be much sickness.

But even if there be a fever, there may exist certain symptoms which point out that emetics are improper. To two of these symptoms we shall shortly advert. First, if there be intense pain at the pit of the stomach, with heat, and a red tongue, proving inflammation to exist there, emetics may do more harm than good; and, secondly, if there be extreme affection of the head, not merely headache, but high delirium or stupor, emetics should not be given without medical sanction. After the emetic has operated, the bowels should be opened; to adults, four or five grains of calomel may be given, followed in an hour by a dose of tartrate of soda in senna tea. The farther management of the case must be left to the medical attendant. Under the head "Management of the Sick-room," we shall describe more fully the domestic treatment of a case of fever, and detail the symptoms to be particularly attended to, and to be mentioned to the physician.

SUBSECT. 3.—*Erysipelas.*

7147. This is also a febrile disease; but one of its essential characters is an inflammation of the skin. The skin is red, and this redness rapidly spreads; it is accompanied with swelling, of a variable amount, often very considerable. When it attacks the face, the appearance of the patient is totally altered by the swelling; all the features are confused, the eyes are concealed, the expression distorted; the person would not be recognised by his nearest friends. With all this there is high fever, with quick, full pulse, thirst, vomiting, violent shivering, constipation, and, at a later stage, and in certain forms of the complaint, sinking and exhaustion.

The chief domestic treatment is to obey implicitly the medical directions, particularly as to the *constant* application of warm or cold lotions, as may be recommended. The rags with which such lotions are applied must be constantly wetted; if they are suffered every now and then to become dry, they not only lose their effect, but become positively hurtful. If erysipelas attack the head and face, it is a dangerous disease. Any approach to delirium or stupor, any anxiety as evidenced in the expressions, or any giddiness or faintness, should be looked out for, and should be instantly communicated to the medical man, as inflammation of certain parts within the scull may come on, and be with difficulty restrained.

One of the best topical applications in erysipelas is an acidulated solution of nitrate of silver, as employed by Dr. A. T. Thomson. The solution is made with a drachm of nitrate of silver, ten drops of nitric acid, and an ounce of distilled water. This is pencilled over the inflamed parts, extending to a little beyond them, and leaving it to dry It blackens the skin at the time, but the cuticle exfoliates and leaves the surface health in a few days.

SUBSECT. 4.—*Inflammations of Lungs, Bowels, Eyes, &c.*

7148. This most important class of diseases cannot be described with any effect. Several inflammatory complaints, as croup, inflammation of brain in children, sore throat, &c., have been already mentioned Cough, breathlessness, expectoration, with high fever and anxiety, should arouse apprehension, and lead to the suspicion of *inflammation of lungs*. No time should be lost in seeking medical aid. If, with a short, dry cough and breathlessness, there be a sharp pain in the side, increased by movement, coughing, or a full breath, *pleurisy* may be apprehended, and should be at once attended to. If there be a constant pain over the bowels (abdomen), increased by pressing on them with the hand, and not coming on in paroxysms, *inflammation* may be present *here* also, and the assistance of a medical man in determining the case is necessary. In these cases, before the medical attendant arrives there may be some good effected by opening the bowels. If the affection be in the chest, this may be done by calomel (four, five, or more grains, according to age, strength, and sex), followed by castor oil. If the disorder be in the bowels, it is better to give castor oil alone, till calomel be sanctioned by the physician. In all cases, also, mustard poultices, kept on for twenty minutes or half an hour, are serviceable; and if medical aid cannot be procured for some time, leeches may be applied, and the bleeding promoted by warm bread poultices. Leeches should not be applied on the bowels of children unless a medical man be by, for it is extremely difficult to arrest the bleeding. One plan that will often succeed is, to wipe the blood clean off, and then at once to sprinkle into the little orifices a small quantity of flour; this mixes with the blood, and often stops its flow. Plaster of Paris may be used in the same way, and is still more efficacious.

7149. *Inflammation of the Eyes.*—Inflammation may exist in various parts in the eye. At present we wish merely to describe the inflammation of the external superficial coats.

In *adults*, inflammation always attracts notice; there is heat and running from the eyes, pain, and a feeling as if sand or some gritty substance was lodged in them; they become reddened, or what is popularly called blood-shot; the eyelids adhere to each other in the morning. Warm milk and water applications, and leeches, may be applied on the lids, and at the external part of the eye. Medical directions should be strictly attended to.

In *children*, inflammation of eyes is often very violent, and may occur a few days after birth: there is a yellow discharge from the eyes; the eyelids are swelled, and stick together; the light hurts the eyes, which are with difficulty opened; when opened, they are seen to be very red. Certain local applications become necessary, and are applied by the surgeon; the eyes, also, should be assiduously bathed with tepid water, to which some goulard lotion may be added.

7150. *Scrofulous Inflammation of Eyes.*—The eyes in this case are little reddened, but have a great aversion to the light; the child almost constantly keeps them closed, and the eyelids are spasmodically contracted when they are attempted to be separated. A discharge, often thin and watery, oozes from the eyes, and the eyelids adhere together in the morning. Certain local applications are always applied by the surgeon: the health should be carefully attended to; good and nutrient food plentifully given; and change of air, sea bathing, and tonics are often of essential service. The child should be prevented rubbing the eyes, and in the morning they should be gently bathed with tepid water, or milk and water, before opening them. When examined, the eyes must be turned away from the light.

SUBSECT. 5.—*Apoplexy.*

7151. A person is said to be in an apoplectic fit when he falls down suddenly and lies on the ground without moving, breathing deeply, and in a peculiar manner drawing in the cheeks, and then suddenly puffing out the cheeks and lips; when examined, the eyes are seen to be staring; the pupil much enlarged; the face is often swollen, red, and turgid; the pulse is full, strong, and often slow, and, as it is termed, labouring. If such an attack occurs in a man of matured manhood, of a full body, and accustomed to live well, and particularly if it occurs two or three hours after a meal, the probability of its being apoplexy is very much strengthened. In such an attack a medical man must instantly be sent for; and all that can be done till he arrive is to loosen the neckcloth and raise the head. It is often directed that vomiting be induced by putting the fingers into the throat; this direction, however, is incorrect, for not only is the strain caused by the vomiting likely still more to increase the mischief going on within the head, but as the attack occurs generally not immediately after a full meal, but two or three hours after, when an increased quantity of circulating fluid is added to the blood, such vomiting will not dislodge anything from the stomach, and cannot possibly be of the slightest service. After an attack of apoplexy, when palsy has not resulted, the diet should be carefully attended to; often vegetables alone must be taken; animal food and fermented liquors are inadmissible; the bowels must be regulated by medicines; gentle exercise assiduously taken, and all sudden exertions or movements, or severe mental excitement, cautiously avoided. There are many symptoms which sometimes point out the approach of apoplexy, as giddiness, great drowsiness, loss of sight or hearing, failure of memory, loss of muscular power, or twitchings of muscles, &c. When any or all of these occur, medical aid should be immediately sought for.

SUBSECT. 6.—*Palsy.*

7152. This may remain after an attack of apoplexy, or may occur *per se* suddenly, when it is called a stroke of palsy, or gradually, when it is termed creeping palsy.

When we treat of the sick-room management we shall take an opportunity of describing more fully the domestic management of this disease.

SUBSECT. 7.—*Epilepsy.*

7153. An epileptic fit, when once seen, is not likely to be forgotten. A person suddenly utters a loud and piercing scream, and then stands fixed and rigid, with every muscle in powerful action for a few moments, then falls and becomes quite insensible; the eyes are rolled upward and inward, the hands clenched, the limbs convulsed, the features distorted, the head rolled from side to side, or bowed up and down; there is foaming at the mouth, and the tongue is protruded and bitten. After a time, these symptoms gradually subside, and the patient sinks into a torpid state for some hours, from which he awakens drowsy, heavy, and incapable of exertion. The scream at the commencement is very characteristic; when once heard, it can never be forgotten; on hearing it, a parrot has been known to drop from its perch to the bottom of its cage, as if stupified by terror. It does not occur, however, in all cases, and often attention is first directed to the patient by seeing him fall heavily to the ground. Persons subject to epileptic fits after a time undergo a peculiar change in feature; the face enlarges and grows coarse, the finest countenance becomes plain, the lips and cheeks become bloated, and of a white, unhealthy hue, the eyes look dull and inexpressive, memory is impaired, the finer qualities of the mind are totally lost, and in some cases, after a variable time, insanity in some one of its numerous forms, most frequently in that of imbecility, consigns the unfortunate patient to confinement. During the fit of epilepsy, all that can be done is to loosen the neckcloth, and to lay the patient on the floor or bed in such a way that his struggles may do him least injury; the movements should not be restrained, any attempt to do so often increasing their violence; when the tongue is protruded and bitten, it is always necessary to put pieces of cork or thick pasteboard between the teeth, so as to keep the mouth open; they should be placed near the angles of the mouth, between the large molar teeth.

The treatment of epilepsy between the fits is far too lengthy a subject to be treated here; we shall only remark that the best medical treatment will fail if not assisted by attention to habits and modes of life; there are certain habits of a pernicious kind, to which it is impossible to allude more particularly in this place, which sometimes produce the disease, and always augment its violence; if these are not discontinued, the epilepsy will not cease; "there is no cure for it in the medicine chest, no, not in the best-furnished apothecary's shop."

Besides these, it is necessary to avoid excitement of all kinds, too much study or attention to business; to abstain from the luxuries of the table, to take regular exercise, and to attend to the state of the secretions.

SUBSECT. 8.—*Insanity.*

7154. On this subject it is not our intention to make any remarks. The brief sketch which our space would allow to give to this subject would be more likely to mislead than to instruct; we shall content ourselves with enumerating the three great rules of what is called the "*moral treatment*" of insanity, and which have been laid down with great clearness by an admirable French writer, M. Georget. These rules are:

1. The ideas and passions of lunatics on the subject of their delirium must never be excited; 2. Their unreasonable opinions must never be opposed by argument, opposition, or ridicule: there are some exceptions to this rule, and some cases, unfortunately few in number, which are benefited by a kind and careful discussion; 3. New ideas and affections must, if possible, be excited in their minds, and their attention directed to subjects foreign to their hallucination. Their bodily health must be promoted by the usual means of diet, cleanliness, and exercise, and which will be more alluded to in the Section on "Convalescence."

SUBSECT. 9.—*Gout.*

7155. It seems scarcely necessary to describe an attack of gout. The most usual form is as follows: The attack commences in the night suddenly with a sharp pain in the ball of the great toe; it comes on in twinges, and soon becomes very severe: the toe swells, and the skin becomes red and shining over it; after remaining at a height for several hours, or for two or three days, the pain subsides, and the swelling and redness gradually disappear, and the cuticle peels off. Previous to an attack of gout, certain symptoms occur which are of great importance, because, if taken in time, the approaching attack may be warded off. These symptoms are often those of indigestion; viz., heartburn; pain at the pit of the stomach; a load there after food; acid eructations; a white tongue; costiveness; high-coloured and scanty urine, with a red deposite; wakefulness; and perhaps flying pains in the limbs. If, when these symptoms occur in a person who has previously had gout, the diet were reduced, blood-letting practised, if the habit were full and gross and the pulse strong, and purgatives taken, particularly colchicum, in the doses presently to be mentioned, the approaching attack may be at once arrested.

The most usual form of gout is one that requires abstinence and exercise; even in habits the most predisposed, attention to the circumstances will secure freedom from the disease. When the attack has occurred, its duration and severity are often lessened by medical treatment. Into this subject we cannot enter, but we may remark that if the patient take colchicum without the sanction of his medical attendant, it must be with great caution; the dose should not exceed twenty drops (or minims, measured in the glass formerly recommended), combined with calcined magnesia and with Epsom salts (sulphate of magnesia). The colchicum should not be too frequently repeated, and directly it purges it should be discontinued; it should also be left off if there be great pain at the pit of the stomach.

There is another form of gout, occurring in pale, feeble, and emaciated subjects, and aptly enough termed "poor man's gout." In this case the homely maxim which has been applied to the above-described plethoric gout, viz., "living on sixpence a day, and earning it," will not answer: good food, tonics, and wine are necessary for its cure. When, in long-continued gout, the joints become swelled and painful, and the gout stones are forming, local counter-irritation by means of lunar caustic or ether, covering the part, at the same time, with oiled silk, is often serviceable; but it must be remembered that this is temporary merely, not striking at the root of the evil. If, during an attack of gout, the pain quit the great toe, or knee, or hand, or whatever part it happened to be located in, and the swelling and redness disappear, and if, at the same time, there ensue an agonizing pain in the stomach, coming on in paroxysms, it may be useful to know that laudanum may be of the utmost service in doses of twenty drops every hour, till the medical man come, who will probably give larger doses, and hot bottles should be unceasingly applied to the region of the stomach. If laudanum cannot be procured, strong brandy is the best substitute; but this is a more dangerous remedy, since the pain *may* be inflammatory, and not spasmodic, and in such a case brandy would do much more harm than opium.

SUBSECT. 10.—*Rheumatism.*

7156. This disease is popularly divided into two kinds, the acute and the chronic.

The *acute* variety is commonly known by the name of "*Rheumatic fever:*" there is intense pain in some of the joints, namely, the knees, shoulders, and wrists, which is not stationary in one place, but migratory and wandering, attacking violently one joint, then leaving this and fastening on another, and then passing on to a third, or returning to the one most affected; the painful joint is swollen, and the skin over it is red, although not always; the slightest movement gives excruciating pain: there is high fever; great heat of skin, and thirst; quick, full pulse; white tongue; copious acid perspirations at night; loss of appetite, &c. The pains are almost always worse during the night, and, as a general rule, are increased by heat.

Such a disease, painful as it may be, is rarely fatal; but it has sometimes consequences of a nature so serious, that it becomes one of the diseases which the physician is most anxious to cut short. There is a great tendency to disease of the heart; this is often very insidious, denoted only by violent heating, or not even by that, and the patient may deny that anything at all is the matter with the heart; but the stethoscope, the most valuable addition to modern medicinal science, reveals the mischief, which, never making a sudden impression, nevertheless pursues its sure and dangerous course, and leads eventually to some of the most fatal diseases of the heart; or, in other cases, there is intense pain and inflammation of the heart, producing a state not likely to be overlooked.

We have made these remarks for this reason: these affections of the heart are comparatively rare in the middle and higher classes of society, where medical aid is always at hand, but they display themselves in their greatest violence among the indigent and half destitute inhabitants of large manufacturing towns, and the poor agricultural districts. Those charitable individuals who "go about doing good" in these haunts of misery are quite unaware of this circumstance. Knowing that rheumatic fever has a tendency to remit in two or three weeks, they fancy it is a disease which will be cured without much aid, and thus a complaint which requires the closest attendance is left to inflict its utmost ravages without impediment. Rheumatism, thus left to itself, subsides, in a great degree, in from two to six weeks; the joints are left stiffened and a little swelled, and subject to pains during damp weather and changes of temperature; a second acute attack occurs after a time, and may be again and again repeated. At length comes a time when the affection of the heart begins to display itself in palpitation, faintness, and irregular pulse; and then livid lips and breathlessness, cough, and, from time to time, a bloody expectoration; finally, general dropsy occurs, and other organs become engaged in the disease, and assist in the fatal termination. The other variety of rheumatism, termed "chronic," from the length of time it lasts, may succeed to an attack of rheumatic fever, or may be of the same character from the commencement. It is not nearly so often followed by heart disease, and is altogether a less dangerous complaint; when it affects the small joints (a disease called by some "*Rheumatic gout*"), it thickens them, renders them stiff, and enlarges the ends of the small bones. With regard to the domestic treatment of rheumatism, we shall delay its consideration till we treat of the "Management of the Sick-room."

Subsect. 11.—*Scrofula.*

7157. This is one of those diseases which are transmitted hereditarily, that is to say, if one parent, and still more if both parents have scrofulous tendencies, the children will, in all probability, also be liable to them. But, moreover, in the most healthy children, bad food, want of proper exercise and cleanliness, and, in fact, all debilitating causes, produce the same effect as hereditary predisposition. Scrofula shows itself under a variety of forms, as enlarged glands, sores, rickets, diseases of bone, as of spine, shin bone, &c., or it affects the eyes, as has been already described under the title "Scrofulous Inflammation of the Eyes." Certain diseases are more common in scrofulous children, as water on the brain (*hydrocephalus acutus*), and the disease termed "*tabes mesenterica*," and chronic inflammation of the membrane lining the bowels (chronic peritonitis). All these diseases are of a serious nature, and demand particular treatment; they have this in common, however, that, springing from one common cause, the fundamental principle of treatment is the same, viz., to give strength to the body: but this general principle is modified by others, as, for instance, in scrofulous disease of the spine, which produces a projection backward of one or more of the bones of the spine, rest and counter-irritation are needful, and in chronic peritonitis, leeches, &c., are necessary.

To take one of the common scrofulous diseases, *rickets*; in this case the bones are bent and distorted, the ends enlarged, the breast pigeon-shaped, the spine curved, and the belly enlarged; and this state of things has, in all probability, been the consequence of neglect, bad food, and deficiency of exercise. This disease is often very tractable by regulating the bowels by alteratives, by nutritious food and tonics cautiously given, and, among other tonics, nothing is better than seaside bathing; and by regular exercise the health improves, the bones get straighter and more in proportion, activity and strength are regained, and many persons, rickety in their youth, grow up to be very athletic subjects. For some observations on the proper method of nursing rickety children we refer to Book XXVI., Chap. I.

7158. In another affection, *scrofulous ulcers*, the same general treatment is necessary, viz., good food, sea bathing, regular exercise, and regulation of bowels. Applications are applied to the sores themselves; we prefer these to be of a simple kind, believing more good to be effected by attending to the health generally than to the sore itself.

7159. In *enlarged scrofulous glands* the same general principles are to be carried out, and, in addition, medicines are used internally and externally, to lessen the bulk of the glands. Iodine, in some form or other, is generally employed; but this must be left to the medical attendant.

7160. It is customary to say that *scrofula* is denoted by certain marks, viz., a light, fair complexion, light and glossy hair, a large pupil with a blue iris, a large upper lip, considerable intellectual power, &c.; but a dark, sallow complexion, with long black hair, and a muddy dark eye, are quite as often marks of scrofulous tendency. And it may be fairly stated that a child will possess any or all of the above characters, and yet not be scrofulous in the least degree. If a child be born of scrofulous parents, it may, by proper attention, be brought through the perils of childhood, and the predisposition corrected. For this purpose, it is usually directed that a wet nurse should be employed, and that the mother should not suckle her infant herself: the child should be sponged all over the body every day with cold or tepid salt and water, according to the season and to the strength of the infant; after this it should be well dried, and friction employed plenty of exercise should be taken, and the natural cries and movements of the child should be encouraged, and not repressed; the sleeping apartment should be lofty and well ventilated; and country air is always desirable, or, at least, some time in every year should be spent at the seacoast.

7161. After weaning, the diet should be as nutritious as possible, without overloading the stomach; sea bathing and exercise are as useful, or more so than before; exposure to cold and damp should be avoided; and in children of forward intellect the development of the mind must be rather repressed than forwarded, and the contrary in children of dull and heavy minds.

Subsect. 12.—*Consumption.*

7162. We propose, in this place, to describe only the early symptoms of consumption, and the mode of life requisite in one predisposed to it. Under the head "Management of the Sick-room" we shall enter more fully into the means employed to afford alleviation to those who suffer under the more advanced stages of the disease. Although a knowledge of the first symptoms of consumption is most desirable, as it is only in an early stage that its formidable progress can be stopped, we feel some difficulty in describing these in the short manner which our space renders necessary; we feel that much needless anxiety may be caused, as every one of those early symptoms of consumption, recognisable by a non-medical person, may be present, and yet the individual be free from all taint of disease. Nevertheless, as consumption is so frequent and so fatal a disease in this country, we shall run the risk of occasioning sometimes unnecessary uneasiness in the minds of friends and parents, in order that we may, in some instances, afford assistance in the early detection, and consequent treatment, of this formidable malady. The personal appearance which has been described as indicative, to a certain extent, of scrofula, is also a sign of consumptive tendency; the age most liable to consumption is that between fifteen and thirty; perhaps its most frequent time of appearance is at the period of the cessation of growth.

7163. A short account of the nature of consumption will more clearly than anything else prove to parents what great necessity there is for an early detection of the disease. The complaint consists essentially of the deposition of a new and foreign substance in the material of the lungs. This substance, in an early stage, is often in the form of little grains of a whitish or pearly colour, and it is very remarkable that these are most usually greatest in number at the summit of the lungs; indeed, just at the part where, in young women, the custom of society ordains that the dress shall cease. When these whitish grains are few in number and small in size, they produce no symptoms whatever which can be noticed by a by-stander, except a little hacking cough, with trifling expectoration, and which is most noticeable in the morning, or may appear only at that time; sometimes there are also slight pains in the chest, but not in every case, and occasionally there are feelings of languor and lassitude. Now it is at this time, during the presence of this little hacking cough, when the little grains are few and small, that there is the greatest chance of cure; and it is precisely this stage which is most commonly overlooked. Supposing it to be overlooked, the deposition of these grains continues; they become united, and form masses and knobs of a grayish, dense substance, which acts as a foreign body on the lungs, and causes inflammation, exudation of fluids, and ulceration; the gray substance also becomes yellowish, or a yellowish substance is at once deposited, and this is known by the name of "*tubercle*." At this period there is the continued cough, the breathlessness, the spitting of blood, and the loss of flesh and strength, which, perhaps, for the first time attract attention, and medical aid is sought for; but it must be obvious to every one who has read these remarks, or any others upon the disease, that medicine can have little power over a disease of such extent; the time has been overlooked during which skilful and prompt attendance would have been of the greatest service; the physician cannot undo that which inattention and negligence have suffered to proceed so far; he stands by, a spectator of events he cannot check, and has the additional mortification of hearing his art condemned for errors not its own.

The symptoms which denote the earliest stage, viz., the slight hacking cough, the slight expectoration, which may be altogether wanting, the flying pains in the chest, and the languor and feeling of illness, are, in many cases, merely accidental, and present in those whose lungs are quite free from disease; but they may derive significance and importance from occurring in persons of a weak frame of body, or who have a hereditary liability to consumption: in all cases, but particularly in these latter, it is advisable to have the chest examined by some competent stethescopician; if disease be present, it is in the state most amenable to treatment; if absent, the examination will, at least, have removed painful apprehensions. In some cases spitting of blood is an early symptom; medical aid should always be obtained, and no foolish fear of alarming the patient should prevent the relations from a prompt and satisfactory investigation. There are many other symptoms in the early stage which are less obvious, and consequently less important, recognisable only by the practised eye of the discriminating physician.

Treatment necessary in Persons liable to Consumption.—The treatment is comprehended under the two following general heads: 1. To increase bodily vigour to the utmost; 2. To ward off inflammation of air tubes; and all circumstances which may tend to develop the latent predisposition. The first rule comprehends the usual means which improve health; such as regular exercise, nutritious and unstimulating diet, attention to the bowels; in summer, the cold or tepid bath, sponging the chest with salt and water, and using friction afterward: in persons of pale face and languid habits, steel wine continued for several months is useful; sea bathing may be combined with it, and, in fact, the "tonic regimen" must be employed. It is of great importance to allow the lungs full play; all fancied elegance of person must be sacrificed for health. The use of tight stays should be discontinued; and the dress should reach quite up to the neck, and in winter be lined with flannel; the upper part of the chest should never be left uncovered. Under the second rule we would particularly mention climate; the great use of Madeira, the Cove of Cork, Hastings, Undercliff, &c., is that they are not so subject to those sudden inequalities of temperature which, in susceptible persons, excite constant little recurrences of slight inflammations of the air tubes of the lungs; in consumptive persons every return of such inflammation is productive of harm; the substance, which, when deposited in the lungs, constitutes the disease, has much less chance of removal when every few days a cold, moist wind, or a sudden dry, east wind, sets in and augments the cough by adding little inflammations to the evils already present. A respirator is also useful, by rendering the air entering the lungs of a more equable temperature. Confinement in rooms kept warmed has also this good effect, but this mode of treatment has the disadvantage of diminishing health by want of due exercise, and by the exclusion of fresh air.

These remarks are made in the most general manner, as in every case the medical man must give such directions as are demanded by the particular state of the person; and hardly any two cases of consumption demand exactly the same minutiæ of treatment, although most of them agree in the main points.

Subsect. 13.—*Indigestion or Dyspepsia.*

7164. If one were to enter fully into the subject of indigestion, he might write a volume in the place of a few paragraphs; it would be necessary to consider the various kinds, and the diet and the medicines necessary for each: but as several works on diet and regimen, and which necessarily comprise the subject of indigestion, have been published within the last few years, we shall make no apology for dismissing this disorder in a few lines.

A person is, in common language, said to be dyspeptic when the appetite is impaired or lost, when there is a load and weight at the stomach after taking food, with eructations of gas, and sometimes of an acid fluid, into the mouth; accompanying these symptoms is nausea, and occasionally sickness, with a tense headache at the back of the head, or localized over the eyes; very often also there are dark specks before the eyes, and the eyes themselves look heavy, yellow, with a dark circle beneath. The tongue is red; the papillæ small, but elongated, and the organ itself enlarged, indented by the teeth, or pale and enlarged in the same way, or covered with a white or yellow fur; the bowels are costive; the water high coloured, and with a red, or, more rarely, a whitish sediment. Such are a few of the more prominent symptoms of the different kinds. With regard to the treatment, this must be left to the physician. We may remark that the practice of taking wine and spirits to force appetite cannot be too much condemned; it is as bad as the indiscriminate use of tonics, which used to be the routine practice of the half-educated medical men of former days; in many cases the mucous membrane is in a state approaching to inflammation, and the treatment is by means of leeches, counter-irritants, alterative medicines, and a diet light, unirritating, and strictly adhered to; however, in a certain class of cases, tonics, wine, and a generous diet are to be used; but the discriminating between these two very opposite cases must be left to the physician. We may remark that some very insidious and dangerous chronic abdominal complaints are ushed in by dyspeptic symptoms; these are generally treated by the patient himself, and usually also aggravated by such treatment: we strongly recommend all dyspeptics to apply for competent aid, if they find their complaints to resist their own treatment for two or three weeks.

Subsect. 14.—*Nettle-rash.*

7165. The only diseases of the cutaneous class which we think it necessary to mention are, nettle-rash, ringworm, and the itch. Some persons are much troubled with nettle-rash, a complaint arising from the use of certain articles of food, shell-fish, fruit, &c. In some persons these produce, after a few hours, feelings of tingling of the skin, and then itching and a little burning; soon after the itching has commenced, wheals appear on the skin; these are of a white colour, and the skin around them is often very red; the face is swelled, the eyes closed, and often with all this there is a feeling of nausea and weight at the pit of the stomach. The best treatment is to dislodge the offending matter by an emetic of ipecacuanha (eighteen grains or one scruple of the powder for an adult), and afterward a brisk aperient should be taken; the warm bath often gives much relief: in severe cases, medical aid is necessary.

Subsect. 15.—*Ringworm.*

7166. Many different diseases of the scalp are popularly termed ringworm; to distinguish between these is often a matter of great difficulty, even for a medical man; it is, however, extremely important, as some forms are contagious, that is to say, are transmitted from an affected person to one unaffected; and parents are necessarily very anxious to know whether their children must be separated or not from their play-fellows or ordinary companions. If an eruption be noticed on a child's head, it is very useful to observe exactly its appearance; whether there are little vesicles; whether the fluid in these is clear or white, or light or dark yellow; whether these little vesicles are pointed or flattened, or indented like a section of a honey-comb: all these things must be reported to the physician, as often, before the head is again examined, these vesicles have burst, and the effusion of their contents confounds their characters, and renders it difficult to decide on their real nature. It should also be noticed wheth er the vesicles appear irregularly over a considerable surface, or whether they are at first few in number, and spread as from a common centre. Other things being equal, if the vesicles be round, filled with a clear, not yellow fluid, and irregularly distributed, not spreading in rings from a centre, the chance of its being contagious ringworm is diminished.

Treatment.—Perhaps in all cases it is best to exclude the child from mixing with his companions till the nature of the complaint is made out: the hair should be cut off, but the vesicle should not be broken till the medical attendant has had an opportunity of carefully inspecting the head. If the eruption be clearly the kind mentioned above as being of little importance, a few days will probably remove it. When the case is declared to be ringworm, various remedies are to be tried. Some are useful, but often a remedy will seem to do good at first, and presently appear to lose its effect; various mercurial ointments, strong acetic acid, lunar caustic, alkalies, creasote, antimonial unguents, &c., are among the numerous preparations which are usually employed: we have known some good follow the use of an ointment made with equal parts of powdered gall-nuts and lard; the head should be kept clean, but not be too often shaved. If the disease be obstinate, it is some consolation to know that it often disappears of itself in the course of from two to five years.

Subsect. 16.—*Itch.*

7167. This disease is known by the appearance of pimples and vesicles, which by scratching acquire little black heads. The itching is augmented at night by the warmth of the bed. The disease may generally be known by the peculiarity almost always existing between the fingers, and on the wrists and elbows, when it affects other parts. It never appears on the face. It seldom happens in any but those of dirty habits or trade; common cleanliness will always prevent it.

Treatment.—Among the lower orders sulphur is the grand treatment; it does little good taken internally, but the ointment should be well rubbed in every night and morning. Among the better classes, who occasionally get this disease by accident, the sulphur is usually perfumed. We can recommend another powerful remedy, viz., a strong solution of the iodide of potassium, which should be put over all the affected parts every night, and left to dry on. It has the advantage of having no smell.

CHAPTER V.

ACCIDENTS IN THE FAMILY.

Sect. I.—FRACTURES.

7168. The most inexperienced eye can often detect that a bone is broken, for sometimes the skin is wounded, the muscles are torn, and the bone is plainly seen, with perhaps one end protruding through the wound; but, independent of this, when the skin is not broken, the limb is evidently seen to be deformed, bent, one portion forming an angle with another, and it is obvious that this cannot occur without fracture of the bone. But whether a fracture is plainly discerned or only suspected, the treatment to be employed till the arrival of the medical man is very simple. The limb, if it be a limb, is to be laid in the position easiest to the patient: the easiest position must evidently be that in which the limb is, as nearly as possible, in its natural condition, when the broken bone has no weight to support, and the ends of the bones are prevented from rubbing on each other and the surrounding parts. Therefore, if the leg be broken below the knee, the plan is to put the leg and thigh quite straight, while the patient lies on the back; but if left to itself in this position, the foot must evidently fall to one side or the other, and turn one broken end of the bone upon the other, so it is necessary to keep the foot straight up, either by holding it there, or by means of pillows placed along each side of the limb; and it may be convenient to know that, when the assistance of a surgeon cannot at once be procured, very excellent pillows may be formed extempore, by making some large linen bags, and half filling them with sand, previously dried and sifted; one large bag should be laid under the leg from the knee to beyond the heel, and depressions made in it for the calf and the heel; two or three other bags, longer and less broad, should then be laid on either side of the straightened leg; and by this means the limb is kept quiet, and in a convenient position till such time as the surgeon can arrive and "*set*" the limb by applying splints, which are merely mechanical contrivances, of a less rude kind than the sand pillows described, but serving the same purpose, viz., to keep the ends of the bones together without permitting movement.

Again, when the collar bone is broken, and which may be suspected when the patient cannot raise the hand to the head, it is obviously very important to take off the weight of the arm by means of a sling, and this often gives much relief. A sling should also be used if a fracture of the upper arm is suspected. If a fracture of the lower arm is suspected, the best way is to lie down in bed, and to place the fore arm on the large sand-bag already mentioned, with the arm bent, and the thumb kept up, or, indeed, in any easy position. With regard to all fractures, it is difficult to go wrong, if it be remembered that the principle is to put the limb in the position it would be in were it not broken, and to prevent one end of the broken bone from rubbing upon the other. If the surgeon cannot at once attend, it is often very useful to apply cold water or cold lotions continually to the part, by means of linen rags, to keep down inflammation, in addition to employing the means just mentioned.

Sect. II.—dislocations.

7169. When a limb is out of its socket, it is advisable to replace it as soon as possible, and therefore medical aid should be immediately sought for; beyond this simple remark we shall say nothing, because without much description it would be impossible to tell when a dislocation had occurred; and even then such imperfect knowledge would be dangerous, as a dislocation might be mistaken for, or complicated with, a fracture, and the remedies necessary for the former would do incalculable mischief to the latter.

Sect. III.—contusions, or severe bruises.

7170. In all contusions the dark appearance, and the successive changes of colour which occur in this, are owing to blood poured out from ruptured vessels. In the treatment of contusions, the first thing is to keep down inflammation by means of leeches, cold evaporating lotions (such as one part of spirit of wine and six parts of spirit of Mindererus), and to mitigate pain by laudanum fomentations in the intervals of the applications of the lotions. When the colour begins to change, the absorption of the blood may be accelerated by rubbing the part briskly with camphor liniment, or any common stimulating application.

Sect. IV.—sprains.

7171. In the treatment of sprains the most agreeable remedy is rest, with constant application of warm flannels dipped in laudanum, or warm poppy fomentations; afterward the part may be bandaged with a broad linen roller.

Sect. V.—wounds.

7172. When a severe incised wound (*i. e.*, a cut with a sharp instrument) has been inflicted, and medical attendance cannot immediately be obtained, the attention must first be directed to the bleeding: supposing the wound to be on the arm or leg, if there be a mere oozing, a simple trickling of the blood down the limb, then it will probably soon stop of itself; linen dipped in very cold water may be applied, and it is of great importance to elevate the limb, so that gravity may not assist the flow of blood: thus, if the wound be on the leg, the person should lie on the bed, and the leg be raised high on pillows; if the arm be the part injured, it should be held above the head; but, supposing the flow of blood to be more violent, supposing it to gush out in a large stream, as it would from a large cut vessel, it is necessary to stop such a jet, else so much blood may be lost as to induce alarming fainting; the best plan is to put the finger or fingers boldly into the cut, and press upon the part from which the blood seems to come without any regard to the pain it may give the patient; the finger must not be removed till the surgeon arrive and tie the wounded vessel with a ligature. When the bleeding has stopped, or nearly so, the next object is to bring the sides of the cut into contact, so that they may unite; this is done by means of adhesive plaster, long strips of which are applied, so as not merely to cover the wound, but to draw its sides together; a very little reflection will easily show any one how a particular cut is to be *dressed*, as the covering it with plaster is technically termed. If the wound be not merely a simple cut, but complicated with a severe bruise, the straps of plaster must not be firmly applied, the sides of the cut must not be forcibly pulled together; indeed, if the contusion be very great, and the bleeding moderate, it may be better not to apply plaster at all, but to use warm poppy fomentations for twenty-four or thirty-six hours, or to apply a bread and water poultice.

Sect. VI.—scalds and burns.

7173. *Scalds*, when caused by boiling water, will, it is obvious, be always of the same degree of severity; directly a scald has happened, it is advisable to prevent the action of the air upon it, and this is done by sprinkling it thickly over with flour, or covering it with cotton wool, which must not be removed till the scald is well, which will be probably in ten days or a fortnight. When scalds are caused by water not boiling, the lead liniment recommended for slight burns is the best application.

7174. *Burns* are much more difficult to treat, as they may be of very different degrees of severity; in the slighter kinds, in which there is merely redness and blistering of the skin, cotton wool or flour may be used, as in scalds; or the following liniment may be constantly applied, viz.:

Take of undiluted Goulard's solution of lead (liq. plumb. diacetatis), ½ ounce; olive oil, ½ ounce; water, 8 ounces; mix the oil and lead solution, shake them well together, and add the water; make a liniment, to be applied by a camel's-hair brush to the burned places, or spread upon linen and applied to the parts.

If the burn be more severe, and if a part or the whole of the substance of the skin be destroyed, the turpentine liniment is preferable; if this cannot be obtained from a druggist, then flour should be applied as before. When flour is used to burns and scalds, and the part is kept quiet, the pain soon ceases. If after a burn the face be deadly pale, and the pulse unfelt, a tea-spoonful of wine or brandy, according to the age of child, should be given from time to time.

SECT. VII.—MEANS TO BE USED IN RECOVERY FROM DROWNING AND SUFFOCATION.

7175. When a person has been taken out of the water, and is insensible, he should be conveyed as speedily as possible to the nearest house or cottage; but if there be no residence near, that is to say, within two or three minutes' walk, it is necessary to use the measures for restoring animation on the spot; although recoverable when taken from the water, the patient may die in the ten or fifteen minutes' transit, for want of certain necessary measures. It is necessary that every body should know that death occurs in drowning because the water prevents the entrance of air into the lungs; the small quantity of water which gets into the lungs is of no consequence, and still less that which passes into the stomach which occurs during life, or if the body be not drowned alive; consequently, the direction sometimes given in old books of holding the head down, in order to *drain off* the water, is not only useless, but positively hurtful; but if death occurs from the want of air, it is obvious that the thing needful is to restore air to the lungs as fast as possible, and this is done by artificial inflation. The patient should be laid in the bed, and hot bottles may be applied to the feet; but while these are getting ready inflation must, if possible, be commenced: in the absence of a regular apparatus, it can be readily performed by a pair of bellows; one person should close the mouth, and one the nostril of the patient very accurately, and in the open nostril the muzzle of the bellows should be inserted by another person; then the nostril should be pressed round the muzzle, so that when air is blown it may pass *through* the nose, and not out into the apartment; directly the position is rightly attained, the bellows must be worked, and the air from them will pass into the lungs; the blowing must be very gentle, else some harm may be done to the structure of the lungs; the rising of the ribs will at once announce that the chest is filled with air; then the bellows must be removed, the mouth and nose opened, and the abdomen and ribs pressed upon so as to expel the air; then the bellows must be used again in the manner described, and the series of changes persevered in for a long time, or till recovery occur; during this time warmth may be applied by means of hot bottles, friction, &c. When a house is some way off, and the bellows cannot be procured, inflation may be performed by any person closing the nostrils of the insensible man, and then applying his mouth to that of the patient and blowing into the lungs, then pressing down the ribs as before, to expel the air, and then blowing in again. Before the operator breathes air in, he should make three or four deep inspirations and expirations, so as to change the air in his lungs, and get it as like atmospheric air and as free from carbonic acid gas as possible. These means should be persevered in for a long time; hope should not be given up, for recoveries have occurred under very untoward circumstances.

7176. *Suffocation.*—In many cases the inflation described above is the remedy applicable here also: thus, if a person be suffocated in a brewer's vat, or by any mephitic gas, the body should be brought into the air, and the above-mentioned process must immediately be had recourse to; medical aid, of course, will always be speedily obtained.

[For the recovery of persons drowned, or suffocated by non-respirable gases, experience has shown that to throw suddenly and violently several buckets of water successively against the spine is a mode of concussion which will be found successful if life be not extinct. This method of treatment is of vastly more importance than the inflation of the lungs by bellows, rolling the body upon a barrel, &c., neither of which can be relied on with half the certainty of resuscitation. So soon as by this method the signs of life become unequivocal, by commencing respiration, groans, or involuntary motions of the head or limbs, indicating sensibility to the concussion upon the spine, the body should be wrapped in blankets, and heat applied, as directed in the foregoing section.]

SECT. VIII.—TORPOR FROM COLD.

7177. When a person has been buried under the snow, has been exposed for some time to weather of great severity, or has in any way become half frozen and stupified by excess of cold, the great rule is *to restore heat as gradually as possible:* thus, in some cases, even friction would communicate heat too soon, so friction with snow is employed to ensure a *very slow* development of heat. The person must not be brought into a room with a fire, but be kept in a very cold room, and covered with very light clothes; of course, in the majority of cases, it is not necessary to use frictions of snow; few cases are so severe as to require this. When long-continued friction has partly restored warmth, the individual may be removed to a warmer room, covered with warmer clothes, and the friction made with brandy. When warmth has been still more restored, heat may be more speedily communicated by means of one or two persons getting into bed with the person and warming him with their bodies: warm bottles and cordials must not be used till heat has been restored to a very great degree. The penalties which attend the too rapid production of heat are indeed great; rapid inflammation and mortification of fingers and toes, or even hands, feet, arms, and legs, or nose and ears, ensue, and the person rescued from the cold may be killed by an ill-judging zeal.

The retreat of the French from Moscow affords striking illustrations of the effect of heat too rapidly applied. These unfortunate men, exposed to a degree of cold to which their campaigns in Italy and in Egypt had little inured them, retreated in weather severe even for that cold latitude; their legions, as they marched, left, for those who followed, rows and groups of dead and frozen soldiery; those who were fortunate enough to reach the camp fires at night hastened toward the welcome blaze, and spread out their half-congealed limbs to the heat; in many cases gangrene followed on the instant, and increased so rapidly that its progress could be traced by the eye, or in other instances a kind of fulness of blood pervaded the lungs and brain; the individuals, perhaps, had scarcely breathed the new atmosphere, when, fainting, they staggered back, their limbs swelled enormously, they became devoid of sensibility, and died in two or three hours.

SECT. IX.—ABSTINENCE FROM FOOD.

7178. Here also the return to a natural state of things must be very gradual; if tho abstinence have been of great length, nothing stronger than chicken or veal broth must at first be given, and then by degrees strong beef tea, and after this some light vegetable, or a bread pudding; animal food must not be given for a long time.

SECT. X.—ANTIDOTES TO POISONS.

7179. *Sulphuric Acid, or Oil of Vitriol.*—The children of poor people often accidentally take this acid; it is bought to clean metallic vessels, and children take the half-emptied bottle, standing on the table, and put it to their mouths. The parent is generally at once informed of what has happened; she hears the child cry, and, turning round, sees the bottle in its hand, or, if she has left the room, she easily perceives what has occurred, from the cries of the child, the marks of the acid on its lips, and the empying of the bottle. Of course a surgeon is at once sent for, but it may be useful to know that magnesia or whiting, or chalk mixed up with water, are the best antidotes: the child should drink a good deal of the mixture. If none of these substances can be procured, a piece of soap may be beaten down in water and given, or even common oil, for this sheathes and somewhat protects the stomach from the corrosive effects of the acid.

7180. *Oxalic acid* is sometimes taken by mistake for Epsom salts; the taste is, however, very different, being powerfully acid, and this usually apprizes the person of the mistake he is committing, or if, as sometimes occurs, he has swallowed the draught at a gulp without tasting it, he is convinced that something is wrong from the excruciating and racking pain which almost immediately follows. The great antidote here, also, is chalk, which invaluable fact was first proclaimed by Dr. A. T. Thomson. It should be mixed with a *small* quantity of water, and taken in considerable quantity. Alkalies and soap are, in this case, improper, but carbonate of magnesia is also an excellent antidote.

7181. *Arsenic* is the most common of all poisons; it produces, some little time after it is taken, feelings of heat and pain at the pit of the stomach, which rapidly become agonizing; vomiting soon occurs, first of the contents of the stomach, then of mucus, bile, and blood. Such are the first symptoms, and their occurrence suddenly in a healthy person, and twenty minutes or an hour after a meal or taking anything into the stomach, they excite suspicion of poisoning. The medical man is of course at once sent for, and while he is coming vomiting may be increased, or, if not present, produced by mustard and water, or salt and water; draughts of warm water may also be taken to excite very copious vomiting. If full vomiting, not merely retching, occur, the chance of recovery is greatest. Two tea-spoonfuls of mustard in a glass of hot water will generally make an adult vomit copiously.

7182. *Corrosive Sublimate.*—The early symptoms of this poison are much the same as those of arsenic, but the pain is more violent, and the taste is most acrid and disagreeably metallic. If from these or any other circumstances corrosive sublimate is suspected or known to be the poison, then white of egg beaten with water should be given; it unites chemically with the corrosive sublimate, and the compound formed is quite inert.

7183. *Verdigris.*—If the person be known to have taken copper, or if it be suspected from the smell and the greenish colour of the vomited matters, and from the coppery taste in the mouth, then white of egg, not mixed with water, must be given here *also*.

7184. *Opium and Laudanum.*—These are two poisons very frequently taken by suicides: an overdose of laudanum, or of some preparation of morphia, is also sometimes taken by mistake. It is soon suspected that a person has taken opium; he is found lying in a state of stupor, as if in a fit of apoplexy, breathing heavily, or hardly breathing at all. Now the question is, what is the matter with this person? Has he apoplexy? is it sudden death from some internal disorder, or is it poisoning by opium? Perhaps a bottle or a glass will be found about, and give some clew: the pupils of the eye also are looked at, and found to be much contracted; now in apoplexy they are generally enlarged. The balance, then, is in favour of its being poisoning by opium, and the principles of cure are first to get the opium out of the stomach by emetic—an operation afterward done more effectually by the surgeon with his stomach-pump; or, if the patient can swallow, fifteen or twenty grains of vitriol, "*sulphate of zinc*" (a salt which can be procured from an adjoining druggist), should be given, or mustard and water, as in the case of poisoning by arsenic, or one scruple of the salt called "*carbonate of ammonia*" may be taken, and is a very good emetic. The next thing is to keep off the stupor as much as possible; this is done by making the patient walk about the room, and allowing no sitting down: if the stupor be too deep for walking, two strong men must literally drag the patient round and round the room, so that no repose whatever can take place. Cold water should also be assiduously dashed in the face, and the face and neck flapped suddenly with a wet napkin: this rouses the nervous energy; the patient generally opens his eyes, and he is capable of replying to questions for the space of half a minute or more. The water may be again dashed upon his face and chest as often as he relapses.

CHAPTER VI.

DOMESTIC MANAGEMENT OF THE SICK-ROOM.

7185. *In describing the management of the sick-room*, every circumstance which can contribute to the comfort and convalescence, or, when convalescence may not be possible, to the mitigation of the bodily sufferings of the sick, we have now to consider. These circumstances we shall place under three heads; 1, regarding those of the patient's room and its furniture; 2, of the qualifications of sick nurses; and, 3, of the course they should pursue when attending patients afflicted with severe and tedious or with mortal diseases, such as consumption and palsy.

SECT. I.—OF THE SICK-CHAMBER AND ITS FURNITURE.

7186. *Rooms for the sick*, wherever choice can be exercised, should be of considerable size, lofty, having open fire-places, and, for some cases of disease, a northern aspect.

7187. *Well-ventilated rooms* are, in all cases of illness, indispensable; yet ventilation should be so regulated that no current of air could pass immediately over the patient's bed or chair. It may always be supposed that draughts of air prevail in the direction of the fire-place, from any window or door; and hence in such situations the invalid should not be permitted either to lie or sit. In few cases free circulation of air is of primary importance. A patient in typhus fever suffers seriously from an overheated room; but, when the heat is moderated by the admission of fresh air, he will in a few hours often materially improve, so great an effect does this single circumstance produce.

7188. *In the convalescent stage of scarlatina free ventilation* is no less needful; but even greater care is requisite than in other cases of fever to screen the patient's bed from any current of air; for if the skin of the patient become slowly chilled, its functions are impeded, no reaction takes place, and the peculiar dropsy before mentioned occurs as a sequel to this disease.

7189. *The temperature* of the sick-room should not be below, nor much exceed, 60° of Fahrenheit.

7190. The kind of bedding for invalids is a subject of importance to their comfort. *In some cases* a well-stuffed feather bed is to be preferred to mattresses, which for fever or paralytic patients are not always sufficiently yielding. By the constant pressure of any particular spot on the mattress, the skin becomes inflamed, and a sore sometimes ensues. A feather bed may, however, be too soft, and become easily disarranged; the patient may be too ill to have it daily made and well shaken, and in such case it becomes often lumpy, and more uncomfortable and injurious to the skin than a hair mattress.

7191. *The spring mattresses* are the most unobjectionable of any; they give way easily to pressure, and spring up, by means of their elastic stuffings, as soon as the pressure is removed. They require no daily making, and afford the patient much assistance, from their elasticity, in turning from one side to the other. They are expensive to purchase, but when a long illness occurs in a family the value of one is incalculable.

7192. *The water, or Arnott, bed* is also another valuable contrivance for mitigating the sufferings and weariness of the victims to lingering, yet fatal diseases. In using it, the head and shoulders of the patient must be supported upon some fixed substance, otherwise, being heavier than the limbs, the inclination of the body will be the reverse of that which is natural. On whatever bed a patient lies, it should be large enough to admit of his being removed from one side to the other, to afford changes in the bed linen, as well as to afford relief in posture to the sufferer; or, if the bed be small, a second bed in the room answers the same ends, as well as admitting of daily exposure, for a short period, of the bed and bedding to the air of the room, when it may be again shaken well, made and prepared for the invalid, to whom, when again carried, it will afford renewed relief and refreshment.

7193. *Carpets* in the sick-room are often removed, under the impression of their retaining infection, if the illness be fever; but their removal is sometimes very inconvenient to the patient, causing too much noise, when the nurses are walking upon the bare floors, for the sensitive state of invalids; when this is the case, the carpets should be replaced, and every other means adopted to deaden sound, such as stuffing cotton wool into the window frames, using a wooden poker for the fire, &c.

7194. *Bed curtains*, in febrile cases of illness, should never be entirely closed, nor should the colour of bed hangings be of a vivid description; red is often a painful colour to invalids; green agreeable; so that, when a choice in this particular is possible, the room in which the latter colour is found should be appropriated to the invalid. Curtains should be removed altogether.

Articles useful in the Sick-room.

The minim glass, for the accurate measurement of medicine given in drops, or tea-spoonfuls. (It may be purchased at druggists for 2*s*. or 2*s*. 6*d*. apiece.)

A thermometer, for regulating the warmth of the invalid's room more uniformly than can be done by consult ing either the invalid's feelings or those of the nurse.

Chloride of lime, in cases of illness from fever, should always be kept in a bottle ready for use.

SECT. II.—QUALIFICATIONS OF NURSES FOR THE SICK.

7195. *When a disease is lingering*, or from its character requiring bodily strength in those employed as nurses, the members of a family are often obliged to give up the charge to the *hired sick nurse*, who knows, or ought to know, how to perform many important duties, of which those less accustomed to illness are ignorant. An experienced sick nurse is also quick in noticing changes in the symptoms of the patient's disease, which the relatives, from inexperience, would overlook, and which it may be important for the medical attendant to be informed of. But most sick nurses still require to be superintended by those most interested in the recovery of invalids; they are often inattentive to the needful ventilation of sick-rooms, and to the regulation of their temperature, keeping up the fires, and especially at night; this fault often increases a patient's fever, which it puzzles the physician to account for. Sometimes, also, nurses are careless in omitting, at the precise hours, to give the medicine ordered, and are not always strict in administering the right quantity. In the convalescent stages of fever, they also require to be cautioned in respect to the diet of their patients, which in quantity they are generally disposed to overdo.

7196. *The qualifications of a good nurse should be* good health; strength enough to lift a patient when requisite; activity, wakefulness, cheerfulness, yet with the power of being silent—a noisy nurse being most unfit for sick patients; intelligent enough to understand readily the often indistinctly expressed wishes of an invalid, and educated enough to read the directions attached to the medicines ordered. Her age should not exceed fifty, nor be much less than thirty years. She should be free from any habitual cough, or any habit which might annoy a patient, such as snuff-taking, &c.

7197. A society has been formed in London for the instruction of sick nurses. Those sent out go by the name of the Protestant Sisters of Charity, and are taught to perform all the offices of charity for which the Roman Catholic Sisters of Charity have been so long distinguished. Much good may be expected by the extension of this benevolent institution, for the sisters are engaged to serve the poor as well as the rich; the latter only being expected to afford the pecuniary means of supporting the institution. No money is given to the sisters by the patients or their friends.

SECT. III.—COURSE TO BE PURSUED BY NURSES IN SEVERE AND TEDIOUS SICKNESS.

7198. *During the first week of typhus fever*, in addition to the remedies ordered by the physician, and with which we have nothing to do here, certain things are ordered in the majority of cases, and the performance of which, although most important, is often left to the judgment of an ignorant nurse. For instance, if the skin be hot and the pulse quick, the skin is directed to be bathed night and morning with cold or tepid water, according to the heat of the skin, the age and strength of the patient, and the kind and period of the disease. Now this is a measure not only important as regards ultimate cure, but very important as regards the personal comfort of the patient, since nothing gives more relief and gratification than this bathing of the skin. The best time for doing it is before the bed linen is changed, as at that time it does not matter about any accidental wetting the sheets, but which, with proper management, need scarcely happen. The patient should not be altogether uncovered, but one part should be bathed at a time, and then dried. In bathing the part, it is necessary to use a good deal of water, not merely to rub the body with a wet sponge; the arms, for instance, may be held over a basin, and water freely poured upon them. After free bathing of this kind, the dry and harsh, unpleasant feeling about the skin goes off, and the patient feels relieved and comfortable. This bathing of the skin is still more useful in the early stage of scarlatina, when the skin is usually very hot.

7199. *In cases of typhus* which have continued some time, and in which the patient's strength has been reduced, this free bathing is inadmissible; but if the sponging be ordered in such a case, the physician will probably stand by, and, to prevent any injurious excess in the bathing, see it done himself.

7200. Another remedy, which is almost always used in the early stages of typhus, is the application of cold to the head, in the form of linen cloths soaked in cold water, or evaporating lotion, or ice applied in a way presently to be described. The use of these cold applications to the head is to prevent any congestion and accumulation of blood within it (a circumstance exceedingly common in fevers); or to moderate such accumulation when it does occur; or to keep down any inflammation of the brain or parts belonging to it, for inflammation of the brain or its membranes in various degrees is not unusual in cases of typhus fever. In order to apply cold effectually, it is, in almost all cases, necessary to shave the head, or to cut the hair very short; and to secure the full advantage of cold applications, the finest head of hair must be sacrificed. Parents who, for appearance sake, refuse such a petty sacrifice when life is in peril, are often sufficiently punished by the ill success of the treatment. When the head has been shaved, a cloth dipped in cold water should be applied over as much space as possible; to prevent the pillow being wetted by the water, a piece of common oil silk, which can easily be procured, should be laid under the head upon the pillow. A piece of simple linen is better than soaking a nightcap and puttting it on, as is sometimes done; it is less heavy, and more easily wetted again. The linen cloth should *never* be left on till it is dry; nurses often allow it, when it becomes dry and harsh, and the head gets hotter than before its application. Another way of applying cold water is to fill a large bladder about one third full of water; it moulds itself upon the head, and is not very heavy.

7201. Ice is best applied by pounding it very small, and half filling a large bladder with it; this also moulds itself upon the head, and is a very powerful agent. It should not be suffered to be on the head too long, else it may reduce the heat too much; it should therefore be removed for a few minutes from time to time.

7202. *By letting water fall from some height, drop by drop,* on the forehead of a highly delirious patient, a most powerful effect is sometimes produced; but this is too strong a measure to be had recourse to without the sanction of the medical attendant.

7203. *Another remedy,* often inefficiently attended to, is fomentation of the bowels; this is best done by having two large pieces of flannel, and dipping one into water as hot as can be borne, then wringing it quickly out, placing it on the bowels, and in the course of a few minutes, when it begins to cool, changing it with the other flannel, also dipped and wrung out; and this should be repeated for an hour or more.

7204. *The clothes on the bed* should not be too thick; the physician will of course see to this: if the patient appear cold, hot bottles should be put to the feet; if there be any accumulation of blood in the head, the feet are often cold; in this case they should be wrapped up in flannel, and hot bottles constantly applied.

SUBSECT. 1.—*Early Stages of Fever.*

7205. *During the early stages of fever* there are certain symptoms which must be particularly noticed, and reported without fail to the physician. It should be noticed how much sleep the patient gets, whether this is deep or disturbed, whether there is any confusion or forgetfulness on awakening: this does not of itself prove that delirium is coming on; but as it is really often the commencement of it, it should not be overlooked; during sleep, too, it should be noticed whether the breathing is regular and deep, or whether it is quick and shallow. Any little cough should not be overlooked.

7206. *Again, the nurse should observe whether there is an increase of fever* at any particular time of the day; such increase is denoted by the skin becoming hotter, the pulse quicker by from six to twenty beats; by the face flushing, the eyes becoming more sparkling, and by the patient being thirstier, and complaining more of headache. The number and kinds of the stools, &c., also should be examined into. Patients are often exceedingly thirsty at this period of the fever; they may drink as freely as they like, and of all beverages cold water is the best. Lemonade is not so good, as in such large quantities it tends to disorder the stomach. The patient usually refuses to take any food, and it should not be pressed upon him from any mistaken idea of giving strength, for it is the fever which exhausts as much as the starving, and it is the former which is to be dreaded; get rid of it, and the debility is generally easily remedied; besides, if food be pressed upon a stomach not demanding it, it will do no good; it will not be digested and assimilated properly, but will pass down into, and perhaps stimulate, the intestines, and cause diarrhœa, with certain formidable ulterior consequences. In addition to what has been now said, it is of course essential that such medicines as are ordered should be given regularly at the appointed times, both day and night.

SUBSECT. 2.—*The latter Stages of Fever.*

7207. *In the latter stages of fever* the weakness is the thing with which the nurse has most to do. It is of the highest importance to give the food which is ordered regularly. The patient is perhaps dreadfully emaciated, weakened to the last degree, and, *if left* without nourishment for several hours together, would perhaps fall a victim to debility alone. It is during the night that a person requires most support; it is during this time that such support is most likely to be forgotten. The food should be given frequently, and in small quantities; the exact quantity of food and time of taking it depend upon the weakness and the appetite of the patient, and necessarily vary in each particular case. If wine be ordered also, it should be given frequently, and in small quantities, mixed with water. It should never be forgotten by nurses that wine by itself has no nourishing power; it is only employed by the medical man to sustain the failing strength, by its exciting agency, till such time as the food taken may have, in some degree, restored the tone of the body. If therefore wine flushes the face, quickens the pulse, and excites headache, it is doing too much; the body is over-excited.

7208. *With regard to the kind of food:* at first it must be simple and farinaceous, and afterward a transition may be made to beef tea, veal and chicken broth, &c., to prepare which we refer to the article on "Cooking for Invalids." Also, during the latter stages of fever, great care should be taken to preserve perfect cleanliness—often a very difficult matter, for the discharges are often somewhat decomposed, and of a bad smell; the sheets should be changed every day, or more often if necessary, and when taken off should be immersed immediately in a pail of water ready at the bedroom door, and to which some of *Labarroque's disinfecting liquid* should be added; some of this should also be sprinkled about the room.

7209. *The patient should not be suffered to lie too long in one position*, but should be gently moved from one side to another, because in these long illnesses, if parts be too much pressed upon, they become sore; therefore towards the end of a severe fever the physician generally examines the lower part of the back and the sides of the sick man, to see if there be any appearance of a sore place; if he does not do this, the friends should see to it; this examination should never be left to the nurse alone.

Directly a part appears discoloured, you may be sure it is too much pressed upon; the patient should be placed in some other position, and propped up by pillows; pillows should also be put above and below the part, to take off the pressure. Certain applications are to be used to the part itself; one of the best of these is a solution of nitrate of silver (lunar caustic), the strength of which should be about twenty grains to an ounce of water; a little of this should be painted on with a camel's-hair brush every day. When the spot has gone beyond this slight discoloration, and has become sore, or seems to be on the point of doing so, the most simple ointments are the best, as a mixture of equal parts of lard and oxyde of zinc, or calamine mixed with oil till it acquire a tolerable consistence; these ointments should be spread on linen, and applied constantly over the part; if the sores seem to be spreading, a water bed is often of great service.

7210. *Again, during the latter stages of fever*, everything should be carefully observed; the position of the patient in bed, and whether he spontaneously changes it, is an important point; also the expression of the countenance; the action of the bowels is one of the most important circumstances to be noticed; the stools should always be kept for the physician to see; the mode of breathing and the presence or absence of cough must not be forgotten; it should also be noticed whether the patient is constantly drowsy, and whether, when awake, he be sensible or delirious, or, as it were, childish, which last state is common in convalescence, and goes off as strength returns.

SECT. IV.—COURSE TO BE PURSUED BY NURSES IN CASES OF CONSUMPTION.

7211. It often happens that a patient with consumption will be able to walk in the open air—will, in fact, possess considerable muscular strength till within a short period of death. The chief things which render this period of consumption harassing are the constant cough, the breathlessness, the occasional sharp, flying pains in the chest, the evening fever, which often prevents sleep till towards the approach of morning, and the nocturnal perspirations. When the cough is very severe, certain remedies intended to allay it are always ordered by the medical man, and these often give temporary relief. The chief thing that the non-medical attendant has to do with regard to the cough is to keep the apartment at a temperature tolerably constant, day and night; all sudden changes from hot to cold air, or the reverse, augment the cough; if it be winter, the patient should not proceed from one room to another, and should not go up and down stairs without putting on a respirator. The temperature of the sitting and bed rooms should be comfortably warm, but never very high; towards the evening it should, if anything, be lower than in the morning, as in the majority of cases the pulse gets quicker and the face more flushed towards night; there is, in fact, an accession of fever, and hot rooms are likely to augment this, and, by so doing, add not a little to the discomfort of the patient. When exercise is taken in the open air, it should never be violent; the patient should walk gently, or, at a later period, be wheeled slowly about in a chair; quick walking increases the flow of blood through the lungs, and, as a consequence, augments the cough and the difficulty of breathing. If the weather be tolerably warm, as much outdoor exercise should be taken as can be borne. With regard to the breathlessness, it may be some consolation to know that this is often much less than might be expected from the extent to which the lung is affected; for the system gradually accommodates itself to the means of breathing which still remain to it; and persons who have only a small portion of lung capable of admitting air still may not suffer materially from difficulty of breathing.

The flying pains in the chest, which are sometimes very severe, will, of course, be treated by the physician; mustard poultices may always be applied, and, according to very high authority on this subject (Sir J. Clark), are often of very considerable service.

The fever, which comes on towards evening, *and the night perspirations*, are two very distressing occurrences in many cases; the patient cannot sleep, but tosses about in bed, or occasionally has a short, unquiet doze; towards three or four o'clock in the morning, perhaps, he falls into a deeper sleep, accompanied with great perspiration, and wakens after a few hours, feeling unrefreshed, and weaker than the night before; after an hour or two, however, he gets more comfortable, and returns nearly to the same state he was in on the day before.

7212. *The night perspirations* are, in some degree, under the influence of medicine, particularly some of the mineral acids, as diluted sulphuric acid, &c.; but the feverishness is often very obstinate; it must be tried to be lessened by quiet of mind and body some time before going to bed, and by abstaining from all heating food, or from anything that may stimulate, in the evening.

7213. *In the degree of severity*, consumption varies infinitely in different persons; some are afflicted by pains in the back and abdomen, headache, dreadful paroxysms of cough, and breathlessness, dyspepsia, evinced by loss of appetite, loathing of food, or sickness and pain after taking it, and a load at the pit of the stomach, with acid eructations, and a red, furred tongue, dryness of the mouth, and considerable thirst; in these cases, as in the less severe ones, there may be spitting of blood very copious, or only sufficient to tinge the expectoration; at a later stage there may be excessive pain in the bowels, great headache, delirium, or a kind of stupor, and a most distressing diarrhœa, which speedily exhausts the patient, and reduces him to the last degree of emaciation; and then thrush about the mouth, which ensues, is extremely tormenting. Fortunately, however, consumption does not always have a course so painful to the patient, and so distressing to the witnesses: in some cases, though perhaps not in the majority, the cough is not so constant and violent; the breathlessness is less; the weakness is progressive and sure, but never makes rapid advances; the emaciation goes on slowly; the appetite and the digestion continue good; no diarrhœa or thrush torments the patient; and, as an excellent writer on this subject describes it, "it is an easy descent, *facilis descensus;* the patient sinks step by step, and gentle is the parting of the last filament, when the body sinks to earth, and the soul rises to eternity." (Dr. C. J. B. Williams.)

7214. *One characteristic of consumption* has been often described by medical writers, and noticed with wonder by the attendants; it is an extreme hopefulness of mind: many patients firmly believe they shall recover, even when in the last stage; no amount of experience can eradicate this, and undoubtedly no one could wish to have such a belief eradicated. We have described above two forms of consumption, differing greatly in severity, and our chief object in so doing was to mention that, in many cases, though not in all, it is possible to change a case which at first threatened to be severe into a milder form; of course in many instances, from the great excitability of the patient, the extreme liability to tuberculous deposites, or from the advanced period of the complaint, such a change is impossible; but, fortunately, sometimes, if the diarrhœa and pains in the bowels can be put a stop to, the remainder of life is comparatively tranquil, and free from distressing symptoms. Therefore, if the patient begin to complain of shooting pains in the abdomen, or if there be a diarrhœa commencing, a mustard poultice should be applied, and repeated every six hours, and the physician should be apprized of the state of things: if the pain be in one spot, a small blister, about the size of the palm of the hand, or smaller if the pain occupy less space, may be put on, and this measure sometimes gives great relief. The diet, also, should be changed; animal food, if it be taken, should be left off for a few days, and mild farinaceous articles alone taken; but of course all these details must be left to the attending physician.

7215. *In the latter stages of consumption* thrush often makes its appearance on the lips, tongue, and inside of the cheeks; the appearance of this in children has been already described; and the measures applicable in that case, as borax with honey or water, are useful, also, in this instance. Very little can be done for the delirium or the stupor, both of which are the immediate precursors of death; life seldom continues more than a fortnight after the former has commenced. Many patients have no delirium or stupor, but die suddenly in a paroxysm of coughing.

SECT. V.—COURSE TO BE PURSUED BY NURSES IN CASES OF PALSY.

7216. *In palsy one side of the body loses its power of motion*, either wholly or in great part, and with or without loss of sensation; or the loss of motion may be confined to both the legs, and the rest of the body remain unaffected. The former case (*hemiplegia*) is the more common complaint of the two, although both are far from rare; yet it sometimes follows a stroke of apoplexy, that is to say, when a person recovers from the stupor of apoplexy, he finds he has lost all power over one side of the body, and that his face is drawn to the opposite side; or loss of motion suddenly occurs without loss of consciousness, and this is popularly termed "*a stroke of palsy.*" Palsy may, however, occur gradually, a degree of feebleness being first noticed; and this is called, both popularly and medically, "*creeping palsy.*"

7217. *In this form of the complaint* the patient should at first be kept quiet, and the skin of the affected side should be well washed with warm water every day, and then well dried; and it is a good plan to rub it well with a horse-hair glove, unless there be some particular reason why this should not be done. As soon as possible, the patient should be encouraged to make what use he can of the arm and leg, and if he be quite incapable of any motion, it is a good plan for the nurse or attendants themselves to move the arm and leg every day for about the space of an hour; this prevents the muscles from wasting so rapidly as they would otherwise do from want of use. If a seton be inserted into the back of the neck, the part should, after an hour or two, be covered with a linseed meal poultice; this lessens the irritation caused by the seton.

7218. *In the other form of the disease*, that in which the legs are palsied, (*paraplegia*), and which generally arises from disease of the spinal marrow, the position of the patient must be carefully attended to: if the case be a tedious one, the back is liable to become sore and ulcerated, and this should always be noticed, and if any indications of approaching ulcerations be apparent, the same remedies should be used as were recommended for the same condition in typhus fever. The muscles should be exercised in this case also every day by the attendants. If issues are made in the back, it is necessary to prevent the patient from lying too much on the back, else the issues may become troublesome sores, and nearly impossible to be cured. We shall not describe here the mode of dressing issues, because the surgeon who makes them can explain this in a few words. For farther information the reader is recommended to consult "The Domestic Management of the Sick-room," by Dr. A. T. Thomson.

CHAPTER VII.

CONVALESCENCE.

7219. *The period of recovery is a most important time*, and often requires as much care as the disease itself; the body is weak, susceptible of impression, disposed to take on morbid actions, and, in some instances, a relapse into its previous state may occur from causes which in its healthy condition would not at all affect the body. The management of convalescence is so extensive a subject, so diversified, and requires so much medical knowledge, that it is quite impossible to enter fully into it in a book intended to be popular; our observations, therefore, will be of a simple and general kind.

SECT. I.—DIET IN CONVALESCENCE.

7220. *After a disease has been subdued*, the appetite returns: the object of food is to restore gradually the waste which the body has sustained; the kind of food must be left to the medical attendant, as it will differ in different cases; and for much useful information on this subject we refer to Book VII., "On Food."

The food must be nutritious and easily digestible, but, at the same time, quite unstimulating; in the early days of convalescence wine, spirits, or malt liquor are generally quite inadmissible, except in convalescence from low fevers. In convalescence after fever, but particularly after typhus fever, the quantity of food must at first be very small, and gradually increased; the appetite is usually extremely keen, and relapses are more often brought on by excess in diet than by any other cause. The digestive organs being weakened, and unable fully to perform their office, it is quite impossible that the quantity of food which the patient would take, were it allowed, can be digested; it lies, therefore, in the stomach, causing a load and weight there, and producing sickness and depression, or, passing beyond the stomach, it induces irritation in the intestines, and diarrhœa; when it is known that the intestines are particularly affected in typhus fever, it is at once apparent why an excess of food is so particularly hurtful in convalescence from that complaint.

7221. *In recovery from all fevers* patients must take food frequently, and in very small quantities at a time; they should never be left a whole night without food. When meat is allowed, poultry and game are usually the first things given; the latter is reckoned more stimulating than the former. With regard to the time of taking these, or fish, &c., we shall make no remarks in this place; we wish only to insist on a most important statement, namely, that in recovery from fevers more harm is done by over-feeding than by any other mistake in treatment; people, in general, have a dread of debility, that leads them, without the advice of the physician, to commence stimulating diet, and in their eagerness to escape one evil they fall into another, which has consequences much more dangerous and irretrievable.

Sect. II.—exposure to cold.

7222. This must be particularly avoided in recovery after typhus or scarlatina: in the latter disease it often brings on the dropsy, formerly mentioned.

Sect. III.—exercise.

7223. Exercise must be gradually taken after fevers, and still more care must be employed in recovery from inflammation in the chest; in these latter cases, a warm, sheltered seacoast, as the Cove of Cork, Hastings, or the Undercliff in the Isle of Wight, is the best situation for recovery. We need hardly mention *warm clothing* as essentially necessary to recovery. The advantages of cheerfulness, of forgetfulness of invalid feelings, must be sufficiently obvious. Travelling is useful in some cases of advanced convalescence, and particularly after recovery from disorders of the digestive organs.

INDEX.
